6. Stem from ſix to fifteen feet in height, ſuffruticoſe, biennial, ſmooth. Branches almoſt erect, round and ſmooth or pubeſcent. Leaves alternate, the upper three-lobed, the lower five-lobed; lobes ovate, acute, nerved, ſmooth above but pubeſcent underneath. Petioles five or ſix inches long, roundiſh, patulous, ſmooth or ſometimes pubeſcent. Glandular pores, commonly three, on the midribs of the leaves underneath. Peduncles oppoſite to the petioles and ſhorter, thickiſh, round, ſtriated, pubeſcent, one-flowered. Flowers large, yellow, turning finally red. Outer calyx half-five-cleft; ſegments ovate, acute, ſmooth or pubeſcent, or having black atoms ſcattered over them: inner having three or five minute, blunt teeth. Petals having a purple ſpot at the baſe, and ſmooth on the outſide. Filaments ſhorter than the petals: anthers yellow or ſulvous. Germ roundiſh-acuminate: ſtyle three or five-cleft at top. Capſule ovate-roundiſh, ſmooth, ſometimes dotted with black, three-celled, three-valved. Seeds oblong, eight to twelve, black, eaſily ſeparated from the cotton.

This is the ſpecies which is ſo much cultivated in the Weſt Indies[f], and form a conſiderable branch of their exports.

An emulſion of the ſeeds is recommended in the bloody-flux; and an oil is obtained from them by expreſſion, which ſupplies the boiling-houſe lamps in ſome plantations[g].

Cultivated here in 1759, by Mr. Miller[h].

This and the third and fourth ſpecies are not eaſily diſtinguiſhed, for they vary in the ſize of the parts, the diviſion and pubeſcence of the leaves, the colour of the ſeeds and cotton, the adherence and tenacity of the latter, the number of glands at the back of the leaves, &c. ſo that it is difficult to ſay which are ſpecies, and which are varieties[i].]

PROPAGATION AND CULTURE.

All the ſpecies of Goſſypium or Cotton are very tender, and will not grow in the open air in England. The firſt and third will ripen their ſeeds here, if they be ſown early in the ſpring, upon a good hot-bed; and when the plants are come up, planted each into ſeparate pots, and plunged into the bark-bed to bring them forward: when they are too tall to remain under the frames, remove them into the tan-bed in the ſtove: and when the roots have filled the pots remove them into larger. With this management the flowers will appear in july, and the ſeeds will be ripe towards the end of ſeptember.

The Shrub-Cotton will riſe from ſeeds very eaſily, if ſown on a good hot-bed early in the ſpring: if they are brought forward in the ſame manner as directed for the others, the plants will be five or ſix feet high the ſame ſummer; but it is difficult to preſerve them through the winter, unleſs they are hardened gradually during the warm weather; for when they are forced on at that time, they will be ſo tender, as to render them incapable of reſiſting the leaſt injury. In autumn they muſt be placed in the bark-ſtove, and kept in the firſt claſs of heat, otherwiſe they will not live through the winter in England.

[Cotton is propagated in the Weſt Indies by the ſeed, which is ſet in rows, about five feet aſunder, at the end of ſeptember, or beginning of october, at firſt but ſlightly covered; but after it is grown up, the root is well moulded. The ſeed is ſubject to decay, when it is ſet too deep, eſpecially in wet weather. The ſoil ſhould not be ſtiff, nor ſhallow, as this plant has a tap-root. The ground is hoed frequently, and kept very clean about the young plants, until they riſe to moderate height; otherwiſe they are apt to be deſtroyed by caterpillars. It grows from four to ſix feet high, and produces two crops annually; the firſt in eight months from the time of ſowing the ſeed; the ſecond, within four months after the firſt; and the produce of each plant is reckoned about one pound weight. The branches are pruned or trimmed after the firſt gathering; and if the growth is over-luxuriant, this ſhould be done ſooner. When great part of the pods are expanded, the wool is picked, and afterwards cleared from the ſeeds by a machine called a gin, compoſed of two or three ſmooth wooden rollers of about one inch diameter, ranged horizontally, cloſe and parallel to each other, in a frame; at each extremity they are toothed or channelled longitudinally, correſponding one with the other; and the central roller, being moved with a treadel or foot-lath, reſembling that of a knife-grinder, makes the other two revolve in contrary directions. The Cotton is laid, in ſmall quantities at a time,

[a] Linn. ſyſt. [b] Swartz. [c] Gærtner. [d] Hort. kew. [e] Murray.

[f] Swartz. [g] Browne. [h] Hort. kew. [i] Swartz.

Upon these rollers, whilst they are in motion, and readily passing between them drops into a sack, placed underneath to receive it, leaving the seeds, which are too large to pass with it, behind. The Cotton thus discharged from the seeds, is afterwards hand-picked, and cleansed thoroughly from any little particles of the pods or other substances which may be adhering to it. It is then stowed in large bags, where it is well trod down, that it may lie close and compact, and the better to answer this purpose, some water is every now and then sprinkled upon the outside of the bags; the marketable weight of which is usually three hundred pounds. An acre may be expected to produce from two hundred and forty pounds to that quantity; or two hundred and seventy pounds on an average *.

DESCRIPTION, *&c.*

[Stem shrubby, and climbing like Hops by axillary tendrils. Leaves ovate or oblong-acute, acuminate, or blunt with a point, unequally serrate-toothed, or slightly crenate only, smooth, deep green, alternate, petioled, two inches long. Racemes furnished with one or two leaflets. The male flowers have no pistil whatsoever; but there are three or four flowers in a hundred that have a style without any germ.

Native of St. Domingo, in woods'. Cultivated by Mr. Miller in 1739'.]

PROPAGATION AND CULTURE.

Sow the seeds on a hot-bed early in the spring, and when the plants are strong enough, transplant each into a small pot filled with light rich earth, and plunge the pots into a moderate hot-bed of tanner's-bark, watering and shading the plants until they have taken new root. In winter plunge them into the bark-bed in the stove, and water them frequently. The stems must be supported, and they seldom produce flowers before the third summer.

GRAFTING is the taking a shoot from one tree, and inserting it into another, in such a manner, as that both may unite closely, and become one tree; this is called by the ancient writers in husbandry and gardening, incision, to distinguish it from inoculating, or budding, which they call inserere oculos.

The use of grafting is to propagate any curious sorts of fruits, so as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as are not worth cultivating: but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock, or tree, on which they are grafted; for though the grafts receive their nourishment from the stocks, yet their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration is, that when the stocks on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they will not make near so great progress as they otherwise would do, nor will the fruit they produce be so fair, and sometimes not so well flavoured.

The shoots are termed cions, or graffs; in the choice of these the following directions should be carefully observed. 1st, That they are shoots of the former year, for when they are older, they never succeed well. 2dly, Always to take them from healthy fruitful trees, for if the trees are sickly from whence they are taken, the grafts very often partake so much of the distemper as rarely to get the better of it, at least for some years; and when they are taken from young luxuriant trees, whose vessels are generally large, they will continue to produce luxuriant shoots, and are seldom so fruitful as those which are taken from fruitful trees, whose shoots are more compact, and the joints closer together; at least it will be a great number of years before the luxuriant grafts begin to produce fruit, if they are managed with the greatest skill. 3dly, You should prefer those grafts which are taken from the lateral, or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given.

These grafts, or cions, should be cut off from the trees before the buds begin to swell, which is generally three weeks or a month before the season for grafting; therefore, when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood is cut off with the cion, it will preserve it the better; and when they are grafted, this may be cut off, for at the same time the cions must be cut to a proper length before they are inserted in the stocks; but, till then, the shoots should remain their full length, as they were taken from the tree, which will preserve them better from shrinking; if these cions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month, or longer; but these should be cut off earlier from the trees than those which are to be grafted near the place where the trees are growing.

Having given directions for the cions and grafts, we next come to that of the stock, which is a term applied to the trees intended for grafting; these are either such old trees as are already growing in the places where they are to remain, whose fruit is intended to be changed, or young trees, which have been

been raiſed in a nurſery for a ſupply to the garden: in the former caſe there is no other choice, but that of the branches, which ſhould be ſuch as are young healthy, well ſituated, and have a ſmooth bark; if theſe trees are growing againſt walls, or eſpaliers, it will be proper to graft ſix, eight, or ten branches, according to the ſize of the trees, by which they will be much ſooner furniſhed with branches again, than when a leſs number of cions are put in; but in ſtandard-trees, four, or at moſt ſix cions will be ſufficient.

In the choice of young ſtocks for grafting, you ſhould always prefer ſuch as have been raiſed from the ſeed, and that have been once or twice tranſplanted.

Next to theſe, are thoſe ſtocks which have been raiſed from cuttings, or layers, but thoſe which are ſuckers from the roots of other trees ſhould always be rejected, for theſe are never ſo well rooted as the others, and conſtantly put out a great number of ſuckers from their roots, whereby the borders and walks of the garden will be always peſtered with them during the ſummer ſeaſon, which is not only unſightly, but they alſo take off part of the nouriſhment from the trees.

If theſe ſtocks have been allowed a proper diſtance in the nurſery where they have grown, the wood will be better ripened, and more compact than thoſe which have grown cloſe and have been there drawn up to a greater height; the wood of theſe will be ſoft, and their veſſels large, ſo that the cions grafted into them will ſhoot very ſtrong, but they will be leſs diſpoſed to produce fruit than the other; and when trees acquire an ill habit at firſt, it will be very difficult to reclaim them afterward.

Having directed the choice of cions and ſtocks, we come next to the operation, in order to which you muſt be provided with the following tools.

1. A neat ſmall hand-ſaw to cut off the heads of large ſtocks.

2. A good ſtrong knife with a thick back, to make cleſts in the ſtocks.

3. A ſharp penknife to cut the grafts.

4. A grafting chiſſel and a ſmall mallet.

5. A wedge, to keep open the cleſts in large ſtocks till the inſertion of the graft.

6. Baſs ſtrings, or woollen yarn, to tie the grafts with, and ſuch other inſtruments and materials as you ſhould find neceſſary, according to the manner of grafting you are to perform.

7. A quantity of clay, which ſhould be prepared a month before it is uſed, and kept turned and mixed, like mortar every other day; this is to be made after the following manner:

Get a quantity of ſtrong fat loam (in proportion to the quantity of trees intended to be grafted) then take ſome new ſtone-horſe dung, and break it in amongſt the loam, and if you cut a little ſtraw, or hay, very ſmall, and mix amongſt it, the loam will hold together the better; and if there be a quantity of ſalt added, it will prevent the clay from dividing in dry weather; theſe muſt be well ſtirred together, putting water to them after the manner of making mortar; it ſhould be hollowed like a diſh, and filled with water, and kept every other day ſtirred; but it ought to be remembered, that it ſhould not be expoſed to the froſt, or drying winds, and the oftener it is ſtirred and wrought the better.

Of late years ſome perſons have made uſe of another compoſition for grafting, which they have found to anſwer the intention of keeping out the air, better than the clay before deſcribed. This is compoſed of turpentine, bees-wax, and reſin, melted together, which, when of a proper conſiſtence, may be put on the ſtock round the graft, in the ſame manner as the clay is uſually applied; and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by froſt, which is very apt to cauſe the clay to cleave, and ſometimes fall off; and when the heat of ſummer comes on, this mixture will melt, and fall off without any trouble. In uſing of this, there ſhould be a tin, or copper-pot, with conveniency under it to keep a very gentle fire with ſmall-coal, otherwiſe the cold will ſoon condenſe the mixture; but you muſt be careful not to apply it too hot, leſt you injure the graft. A perſon who is a little accuſtomed to this compoſition, will apply it very faſt, and it is much eaſier for him than clay, eſpecially if the ſeaſon ſhould prove cold.

There are ſeveral ways of grafting, the principal of which are five:

1. Grafting in the rind, called alſo ſhoulder-grafting, which is only proper for large trees; this is called crown-grafting, becauſe the grafts are ſet in form of a circle, or crown, and is generally performed about the latter end of march, or the beginning of april.

2. Cleft-grafting, which is alſo called ſtock, or ſlit-grafting; this is proper for trees or ſtocks of a leſſer ſize, from an inch, to two inches or more diameter: this grafting is to be performed in the months of february and march, and ſupplies the failure of the eſcutcheon way, which is practiſed in june, july, and auguſt.

3. Whip-grafting, which is alſo called tongue-grafting; this is proper for ſmall ſtocks of an inch, half an inch, or leſs diameter; this is the moſt effectual way of any, and which is moſt in uſe.

4. Grafting by approach, or ablactation; this is to be performed when the ſtock you would graft on, and the tree from which you take your graft, ſtand ſo near together, that they may be joined; this is to be performed in the month of april, and is alſo called inarching, and is chiefly uſed for Jaſmines, Oranges, and other tender exotic trees.

[5. Grafting in the root, which is of later invention than any of the former ways, and in many circumſtances may be an improvement of them all.

The ſeaſon for grafting muſt be regulated by the weather. Our climate is ſo uncertain in the ſpring, that it is better to defer it till the circulation of the ſap is briſk, and the buds of the ſtocks are beginning to break into leaves: obſerving only that the weak ſhoots of tender trees will not admit of being ſo long cut as the more hardy.

It is indiſpenſably neceſſary never to graft while it actually freezes or rains *.]

We come next to the manner of performing the ſeveral ways of grafting.

The firſt method, which is termed rind, or ſhoulder-grafting, is ſeldom practiſed but on large trees, where either the head, or the large branches, are cut off horizontally, and two or four cions put in, according to the ſize of the branch, or ſtock: in doing of this, the cions are cut flat on one ſide, with a ſhoulder to reſt upon the crown of the ſtock; then the rind of the ſtock muſt be raiſed up, to admit the cion between the wood and the bark of the ſtock, which muſt be inſerted about two inches, ſo as the ſhoulder of the cion may meet, and cloſely join the crown of the ſtock; and after the number of cions are inſerted, the whole crown of the ſtock ſhould be well clayed over, leaving two eyes of the cions uncovered therewith, which will be ſufficient for ſhooting; this method of grafting, was much more in practice formerly than at preſent; the diſcontinuance of it was occaſioned by the ill ſucceſs it was attended with; for as theſe cions were placed between the rind of the ſtock and the wood, they were frequently blown out by ſtrong winds, after they had made large ſhoots, which has ſometimes happened after five or ſix years growth; ſo that whenever this method is practiſed, there ſhould be ſome ſtakes faſtened to ſupport the cions, until they have almoſt covered the ſtock.

The next method is termed cleft, or ſtock-grafting; this is practiſed upon ſtocks, or trees, of a ſmaller ſize, and may be uſed with ſucceſs, where the rind of the ſtock is not too thick, whereby the inner bark of the cion will be prevented joining to that of

* Boutcher.

the ſtock; this may be performed on ſtocks, or branches, which are more than one inch diameter; in the doing of this, the head of the ſtock, or branch, may be cut off with a ſlope, and a ſlit made the contrary way, in the top of the ſlope, deep enough to receive the cion, which ſhould be cut ſloping, like a wedge, ſo as to fit the ſlit made in the ſtock, being careful to leave that ſide of the wedge, which is to be placed outward, much thicker than the other; and in putting the cion into the ſlit of the ſtock, there muſt be great care taken to join the rind of the cion to that of the ſtock; for if theſe do not unite, the graſts will not ſucceed: when this method of graſting is uſed to ſtocks which are not ſtrong, it will be proper to make a ligature of baſs, to prevent the ſlit of the ſtock from opening; then the whole ſhould be clayed over, to prevent the air from penetrating the ſlit, ſo as to deſtroy the graſts, only leaving two eyes of the cions above the clay for ſhooting.

The third method is termed whip, or tongue-graſting, which is the moſt commonly practiſed of any by the nurſerymen near London, eſpecially for ſmall ſtocks, becauſe the cions much ſooner cover the ſtocks, in this method than in any other.

This is performed by cutting off the head of the ſtocks ſloping; then there muſt be a notch made in the ſlope toward the upper part downward, a little more than half an inch deep, to receive the cion, which muſt be cut with a ſlope upward, and a ſlit made in this ſlope like a tongue, which tongue muſt be inſerted into the ſlit made in the ſlope of the ſtock, and the cion muſt be placed on one ſide of the ſtock, ſo as that the two rinds of both cion and ſtock may be equal, and join together exactly; then there ſhould be a ligature of baſs to faſten the cion, ſo as that it may not be eaſily diſplaced, and afterward clay it over, as in the former methods.

The fourth ſort of graſting is termed inarching, graſting by approach, or ablactation. This is only to be performed when the ſtocks, which are deſigned to be graſted, and the tree from which the graft is to be taken, ſtand ſo near together, or may be brought ſo near together, as that their branches may be united: this method of graſting is commonly practiſed on tender exotic plants, and ſome other ſorts which do not ſucceed in any of the other methods.

In performing this operation, a part of the ſtock, or branch, muſt be ſlit off about two inches in length, obſerving always to make choice of a ſmooth part of the ſtock; then a ſmall notch ſhould be made in this ſlit of the ſtock downward, in the ſame manner as has been directed for whip-graſting; then the branch of the tree deſigned to be inarched, ſhould have a part ſlit off in like manner as the ſtock, and a ſlit made upward in this, ſo as to leave a tongue; which tongue ſhould be inſerted into the ſlit of the ſtock, obſerving to join their rinds equally, that they may unite well together; then make a ligature of baſs, to keep them exactly in their ſituation, and afterward clay this part of the ſtock over well, to keep out the air; in this method of graſting, the cion is not ſeparated from the tree, untill it is firmly united with the ſtock, nor is the head of the ſtock, or branch, which is graſted, cut off till this time, and only half the wood pared off with a ſlope, about three inches in length, and the ſame of the cion, or graft.

This method of graſting is not performed ſo early in the ſeaſon as thoſe of the other, it being done in the month of april, when the ſap is flowing, at which time the cion and ſtock will join together, and unite much ſooner than at any other ſeaſon.

The Walnut, Fig and Mulberry, will take by this method of graſting; but neither of theſe will ſucceed in any of the other methods; there are alſo ſeveral ſorts of Evergreens, which may be propagated by this method of graſting; but all the trees which are graſted in this way are weaker, and never grow to the ſize of thoſe which are graſted in the other methods; therefore this is rarely practiſed, but on ſuch ſorts of trees as will not take by the other methods.

[The fifth method is performed by cutting the clean ſmooth roots of the ſtocks in pieces five or ſix inches long, and as large or a little larger than the graft. Let them be whip-graſted and tied together very cloſe, ſo as to prevent the wet from affecting the wounded parts, and plant them ſo deep, that the graft, which ſhould be four or five inches long, may be about half buried. By this method, the grafts themſelves will root, and a nearer ſimilitude preſerved to the tree from whence the graſts are taken: nay after two or three years the ſtock may be cut quite away, and the graft left to maintain itſelf. In practiſing this method, the graſts may be an inch or two longer than is directed for the others*.]

The next thing which is neceſſary to be known, by thoſe who would practiſe this art, is, what trees will take and thrive by being grafted upon each other; and here there have been no ſure directions given by any of the writers on this ſubject, for there will be found great miſtakes in all their books, in relation to this matter; but as it would ſwell this article too much, if all the ſorts of trees were to be here enumerated, which will take upon each other by graſting, I ſhall only mention ſuch general directions, as, if attended to, will be ſufficient to inſtruct perſons, ſo as they may ſucceed.

All ſuch trees as are of the ſame genus, i. e. which agree in their flower and fruit, will take upon each other: for inſtance, all the Nut-bearing trees may be ſafely grafted on each other, as may all the Plum-bearing trees, under which head I reckon not only the ſeveral ſorts of Plums, but alſo the Almond, Peach, Nectarine, Apricot, &c. which agree exactly in their general characters, by which they are diſtinguiſhed from all other trees; but as many of theſe are very ſubject to emit large quantities of gum from the parts of the trees as are deeply cut and wounded, for the tender trees of this kind, viz. Peaches and Nectarines, which are moſt ſubject to this, it is found to be the ſureſt method to bud or inoculate theſe ſorts of fruits, for which ſee INOCULATION.

Then all ſuch trees as bear cones will do well upon each other, though they may differ in one being evergreen, and the other ſhedding its leaves in winter; as is obſervable in the Cedar of Libanus, and the Larch-tree, which are found to ſucceed upon each other very well; but theſe muſt be graſted by approach, for they abound with a great quantity of reſin which is apt to evaporate from the graft, if ſeparated from the tree before it is joined with the ſtock, whereby they are often deſtroyed; as alſo the Laurel on the Cherry, or the Cherry on the Laurel. All the maſt-bearing trees will alſo take upon each other, and thoſe which have a tender ſoft wood will do well if grafted in the common way; but thoſe that are of a more firm contexture, and are ſlow growers, ſhould be graſted by approach.

By ſtrictly obſerving this rule, we ſhall ſeldom miſcarry, provided the operation be rightly performed, and at a proper ſeaſon, unleſs the weather ſhould prove very bad, as it ſometimes happens, whereby whole quarters of fruit-trees miſcarry; and it is by this method that many kind of exotic trees are not only propagated, but alſo rendered hardy enough to endure the cold of our climate in the open air; for, being graſted upon ſtocks of the ſame ſort which are hardy, the graſts are rendered more capable to endure the cold, as has been experienced by moſt of our valuable fruits now in England, which were formerly tranſplanted here from more ſouthern climates, and were at firſt too impatient of our cold to ſucceed well abroad; but have been, by budding or graſting upon more hardy trees, rendered capable of reſiſting our ſevereſt cold.

GRASS. The Graſſes, ſo extenſively uſeful in rural oeconomy, are chiefly to be found in the ſecond Order of the Third Claſs, (Triandria Digynia) in the Sexual Syſtem.

However numerous they may be, and diſtinct from each other, they generally agree in the following circumſtances; which, taken together, form the Natural Character of this tribe or family. The *Calyx* is a glume or chaff, in moſt ſpecies compoſed of two valves, one larger and globous, the other ſmaller and flat. The *Corolla* alſo is a bivalve glume, and is accompanied by a very ſmall, ſuperior, two-leaved nectarium, of an oblong form. The *Stamens* are three in number; the filaments capillary; the anthers oblong and bicapſular. There are two *Piſtils*, which are pubeſcent, reflex or bent back from each other, and terminated by pubeſcent ſtigmas. One *ſeed* only, or grain, ſucceeds to each flower: it has no pericarp, but is covered by the calyx, corolla, or both; it is of an oblong form, drawn to a point at both ends, and monocotyledonous, or compoſed of one lobe only.

Beſides this agreement in the fructification, Graſſes are known at firſt ſight to perſons totally unſkilled in Botany, by their peculiar appearance, or habit as Botaniſts call it. Their ſtalk is ſimple or unbranched, ſtraight, hollow, and jointed. Their leaves are quite entire, of a long linear ſhape, acuminate or drawing gradually to a point at the end, marked with lines parallel to the midrib or middle nerve. Upon the culm or ſtalk there is only one of theſe leaves to each joint, ariſing from a ſheath which inveſts the ſtalk, uſually to a conſiderable diſtance. The ſeed, it is well known, is farinaceous, or abounding in meal, and is the principal food of many tribes of birds, as the ſeeds of the larger ſorts, which we call Corn, are of mankind.

One genus of Graſs entitled *Anthoxanthum* differs from the reſt in having two ſtamens only. And there are ſeveral genera, which having male flowers mixed with the hermaphrodites are placed by Linnæus in his claſs Polygamia.

Artificial Graſſes, vulgarly ſo called, are moſtly Leguminous plants, totally different in every reſpect from Graſſes, except in being uſed as food for cattle; and are to be ſought for in the claſs Diadelphia.

All the Graſſes are particularly treated of under their reſpective genera and ſpecies, for which ſee the articles *Ægilops, Agroſtis, Aira, Alopecurus, Andropogon, Anthiſteria, Anthoxanthum, Apluda, Arundo, Avena, Bromus, Cenchrus, Cryptis, Cynoſurus, Dactylis, Elymus, Eriophorum, Feſtuca, Holcus, Hordeum, Ischæmum, Lolium, Melica, Miegia, Milium, Nardus, Panicum, Paſpalophorum, Paſpalum, Perotis, Phalaris, Phleum, Poa, Rottboellia, Saccharum, Secale, Stipa, Triticum.*]

Graſs for Gardens.

The Engliſh Graſs is of ſo good a quality for walks or Graſs-plats, that if they be kept in good order, they have that exquiſite beauty that they cannot come up to in France, and ſeveral other countries. But green walks and green plats are, for the moſt part, not made by ſowing the Graſs-ſeed, but but laying turfs; and, indeed, the turfs from a fine common or down, are much preferable to ſown Graſs.

In ſowing a fine green plat, there is a difficulty in getting good ſeed: it ought not to be ſuch as is taken out of the hay-loft without diſtinction; for that ſeed ſhooting too high and making large ſtalks, the lower part will be naked and bare; and although it be mowed ever ſo often, it will never make handſome Graſs; but, on the contrary, will come to nothing but tufts of weeds and Quick-graſs, very little better than that of the common fields.

If walks or plats be made by ſowing, the beſt way is to procure the ſeed from thoſe paſtures where the Graſs is naturally fine and clear, or elſe the trouble of keeping it from ſpiry and benty Graſs will be very great, and it will ſcarce ever look handſome.

In order to ſow Graſs-ſeed, the ground muſt be firſt dug or broken up with a ſpade; and when it has been dreſſed and laid even, it muſt be very finely raked over, and all the clods and ſtones taken off, and covered over an inch thick with good mould, to facilitate the growth of the ſeed; this being done, the ſeed is to be ſown pretty thick, that it may come up cloſe and ſhort; and it muſt be raked over again to bury and cover the ſeed, that if the weather ſhould happen to be windy, it may not be blown away.

As to the ſeaſon of ſowing Graſs, the middle or latter end of auguſt is a good time, becauſe the ſeed naturally requires nothing but moiſture to make it grow: if it be not ſown till the latter end of february, or the beginning of march, if the weather proves dry, it will not ſo ſoon make the walks or quarters green. It is alſo beſt to ſow it in a mild day, and inclining to rain; for that, by ſinking down the ſeed in the earth, will cauſe it to ſhoot the ſooner. But where Graſs is ſown in gardens, either for lawns or walks, there ſhould always be a good quantity of the White Trefoil or Dutch Clover ſown with it, for this will make a fine turf much ſooner than any other ſown Graſs, and will continue a better verdure than any of the Graſs tribe.

After the ſeed is well come up, and the Graſs is very thick and of a beautiful green, it will require a conſtant care to keep it in order: this conſiſts in mowing the Graſs often, for the oftener it is mowed, the thicker and handſomer it grows; it muſt alſo be rolled with a cylinder or roller of wood, to level it as much as poſſible.

If Graſs be neglected, it will run into Quick-graſs and weeds; and if it does ſo, there is no way to recover it, but either by ſowing it, or laying it over again, and that once in every two years; but if the ground be well cleared from the roots of ſtrong weeds, and the turf be taken from a fine level common, it will continue handſome for ſeveral years, provided it be well kept.

In order to keep Graſs-plats or walks handſome and in good order, in autumn you may ſow ſome freſh ſeed over any places that are not well filled, or where the Graſs is dead, to renew and furniſh them again; but there is nothing which improves Graſs ſo much as conſtant rolling and polling it, to deſtroy wormcaſts, and thereby the turf is rendered fine.

It is a general practice when turf is laid in gardens, to cover the ſurface of the ground under the turf, either with ſand or very poor earth; the deſign of this is to keep the Graſs fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not ſo for ſuch land as is but middling or poor; for when this is practiſed in ſuch places, the Graſs will ſoon wear out, and decay in patches.

When turf is taken from a common or down, there ſhould

ſhould be regard had to the cleanneſs of it, and not to take ſuch as is full of weeds: for it will be a very tedious piece of work to weed them out after the turf is laid; and unleſs this is done, the Graſs will never appear handſome.

Where turf is deſigned to remain for years without renewing, there ſhould be dreſſing laid upon it every other year, either of very rotten dung, aſhes, or, where it can be eaſily procured, very rotten tan is a good dreſſing for Graſs; but theſe dreſſings ſhould be laid on early in winter, that the rain may waſh them into the ground before the drought of the ſpring comes on, otherwiſe they will occaſion the Graſs to burn when the warmth of ſummer begins. Where Graſs is ſo dreſſed, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is not dreſſed or fed with ſheep, it will rarely continue handſome more than eight or ten years.

Graſs for Meadows and Paſtures.

The land on which Graſs-ſeed is intended to be ſown, ſhould be well ploughed, and cleared from the roots of noxious weeds, ſuch as Couch-graſs, Fern, Ruſhes, Heath, Gorſe, Broom, Reſt-harrow, &c. which if left in the ground, will ſoon get the better of the Graſs, and over-run the land. Therefore in ſuch places where any of theſe weeds abound, it will be a good method to plough up the ſurface in april, and let it lie ſome time to dry; then harrow the roots into ſmall heaps, and burn them. The aſhes ſo produced, when ſpread on the land, will be a good manure for it. The method of burning the roots is particularly directed under the article MEADOW, which ſee: but where Couch-graſs, Fern, or Reſt-harrow is in plenty, whoſe roots run far under ground, the land muſt be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off after each ploughing, which is the moſt ſure method to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome under-ground drains to carry off the wet; which, if detained too long on the ground, will render the Graſs ſour. The method of making theſe drains is preſcribed under the article MEADOW, which ſee.

Before the ſeed is ſown, the ſurface of the ground ſhould be made level and fine, otherwiſe the ſeed will be buried unequally. When the ſeed is ſown, it muſt be gently harrowed in, and the ground rolled with a wooden roller, which will make the ſurface even, and prevent the ſeeds being blown in patches. When the Graſs comes up, if there ſhould be any bare ſpots where the ſeed has not grown, they may be ſown again, and the ground rolled, which will fix the ſeeds; and the firſt kindly ſhowers will bring up the Graſs, and make it very thick.

Where the land is deſigned to continue in paſture, it ſhould be ſown with the beſt ſorts of Graſs-ſeeds, and white Dutch Clover, or what is commonly called Honeyſuckle Graſs in many parts of England, but there is a great difficulty of procuring hay-ſeeds which are good; for in all the good paſtures near London, which abound with the beſt ſorts of Graſs, the hay is commonly cut before the ſeeds of the Graſs are ripe; ſo that thoſe ſeeds which are procured from the ſtables where the horſes are fed with the beſt ſort of hay, are little more than chaff, or at beſt are only ſuch as are of the early kinds of Graſs, with a great quantity of Plantain and other weeds; which has diſcouraged many gentlemen from ſowing them, nor has any one attempted to ſave theſe ſeeds properly; and as it requires longer time, and more attention, to ſave a quantity of ſeeds of the purer ſort of Graſs than the generality of people care to beſtow, I would recommend the ſetting ſome of thoſe upland paſtures which are cleaneſt from weeds, and have the ſweeteſt herbage aſide, to ſtand for ſeeds; and although by ſo doing the hay will be leſs valuable, yet from the ſale of the ſeeds, it may anſwer better to the poſſeſſor than to mow it merely for the hay; for any gentleman who has regard to the beauty of his land, had better give ſix times the price for ſuch ſeeds, as is uſually paid for the ordinary ſeeds, ſince the firſt expence of ſeeds is not to be put in competition with the beauty and advantage of having ſuch as are good; for when the land is brought to a good ſward, which may be done in one year, where it is properly prepared and ſown with good ſeeds, it may be kept in good order, and by good management improved annually, and will continue ſo as long as proper care is taken of it. I know ſome land which was ſown in the method hereafter directed above forty years ago, which are now as good paſtures as any I have ſeen, and may be always continued ſo.

Theſe grounds abounded with many bad weeds, ſo they had a winter and ſummer's fallow, in which time they were five times ploughed, and ten times harrowed in order to deſtroy the weeds, and make the ſurface of the ground fine; in auguſt they were ſown with the beſt Graſs ſeeds as could be procured, three buſhels of this, and nine pounds of the white Dutch Clover-ſeeds were allowed to each acre; as there happened rains ſoon after the ſeeds were ſown, ſo the Graſs came up well; but among it were a great number of weeds, which were drawn up and carried off the ground, and in the beginning of october the fields were rolled with a barley roller; in the ſpring the fields were again weeded, and afterwards rolled, and that ſummer there was more than two tons of hay per acre mowed off the land; and by conſtant weeding twice a year, ſweeping it with a buſh-harrow, rolling and dreſſing of land, the Graſs has been greatly improved ſince, and is now as good paſture as any in England: and ſince I have laid down great quantities of land in the ſame manner, and with equal ſucceſs, therefore from many years experience can recommend it, as the ſureſt method of having good paſtures.

But I know the generality of farmers will object to the firſt loſs of their crop, and alſo to the after expence of weeding, rolling, &c. as too great for common practice: however, I am well ſatisfied from experience, that whoever will be at the expence, will find their account in it; for the crops of hay will be ſo much better, and the after paſture alſo, that it will more than pay the expence, as from many exact accounts which have been kept of the whole, is ſufficiently demonſtrated, and the verdure of theſe paſtures is charming to all thoſe who have any taſte of natural beauties.

[It is wonderful, remarks the benevolent Stillingfleet, how long mankind has neglected to make a proper advantage of plants ſo important as Graſſes, and which in almoſt every country are the chief food of cattle. The grazier for want of diſtinguiſhing, and ſelecting Graſſes for ſeed, fills his paſtures either with weeds, or ſpecies improper for the ſoil; when by making a right choice, after ſome trials he might be ſure of the beſt graſs, and in the greateſt abundance that his lands admits of. At preſent, if he wants to lay down his land to graſs, he uſually takes his ſeeds indiſcriminately from a foul hay-rick: by which means, beſides a certain mixture of all ſorts of rubbiſh, if he ſhould chance to have a large proportion of good ſeed, it is not unlikely but that what he intends for dry land may come from ſuch as is moiſt, and the contrary.

On this occaſion ſome ſay, that if you manage your ground properly, good graſſes will come of themſelves. But the queſtion is, how long it will be before this happens; and why be at the expenſe of ſowing what you muſt afterwards try to deſtroy by manuring? which muſt be the caſe, ſo long as all kinds of rubbiſh are ſown under the name of hay-ſeeds. Again, if the beſt way be to let the ground take its chance, why is the farmer at the expenſe of procuring the ſeeds of White or Broad Clover, which come up in almoſt all parts of England ſpontaneouſly? But if this be allowed to be the beſt way in relation to Clover of any ſort, what reaſon can be aſſigned why graſs-ſeeds only are not to be ſown pure?

Others ſay, that it is better to have a mixture of different ſeeds. Be it ſo. But is not a mixture by choice more likely to be proper than one by chance? Eſpecially after a ſufficient experience has been had of the particular qualities of each ſort, the kind of cattle each graſs is moſt adapted to, the different grounds were they will thrive beſt, &c. all which circumſtances are now in general little attended to, though of the utmoſt conſequence.

The ſowing of ſeed from a foul hay-rick is indeed ſuch a ſlovenly method of proceeding, as one would think could not poſſibly prevail univerſally; yet this is the caſe as to all Graſſes except the perennial Darnel or Ray-graſs. Now would the huſbandman be at the pains of ſeparating once in his life half a pint or a pint of the different kinds of graſs-ſeeds, and take care to ſow them ſeparately; in a very little time he would have wherewithal to ſtock his farm properly, according to the nature of each ſoil, and might at the ſame time ſpread theſe ſeeds ſeparately over the nation by ſupplying the ſeed-ſhops.

The number of Graſſes beſt adapted to cultivation is ſmall; perhaps half a dozen or half a ſcore at moſt; and how ſmall the trouble would be of collecting ſuch a number, and how great the benefit, muſt ſurely be obvious to every one at firſt ſight. Or if it be thought too great a labour to collect the ſeeds ſeparately, nothing can be more eaſy than to adopt the method recommended by Mr. Miller, of ſelecting patches in paſtures that are free from weeds, and where one of the beſt ſorts of graſs predominates, to let it ſtand till the ſeed is ripe, and then if it be of a ſort that ſheds the ſeed eaſily, to mow it early in the morning, and not to make it as hay, but only when it is dry on one ſide, to turn it over gently on the other, and to threſh it, if convenient, on the ſpot.

Mr. Stillingfleet, in his Obſervations on Graſſes, has ſelected eleven ſpecies, and given figures of them. 1. *Vernal Graſs*, common on dry hills, on ſound rich meadow land, and alſo in woods. It is very early, and likely to be a good graſs for ſheep paſtures. It is very eaſy to gather, for it ſheds its ſeeds upon the leaſt rubbing. It gives a grateful odour to hay. See *Anthoxanthum odoratum*.

2. *Meadow Fox-tail Graſs*, found in great plenty in the beſt meadows about London, and makes very good hay. Linneus ſays it is proper to ſow on grounds that have been drained. It may be gathered at any time of the year from hay ricks, for it does not ſhed its ſeeds without rubbing. See *Alopecurus Pratenſis*.

3. *Fine Bent Graſs*, in great plenty on the beſt ſheep paſtures. See *Agroſtis capillaris*.

4. *Mountain Hair Graſs*, abundant alſo in ſimilar ſituations. See *Aira montana*.

5. *Silver Hair Graſs*, in the ſame kinds of paſtures. See *Aira caryophyllea*.

6. *Great Meadow Graſs*, which together with the narrow-leaved ſort is common in the beſt meadows, and makes both good paſture and hay. See *Poa pratenſis*, *anguſtifolia* and *compreſſa*.

7. *Annual Meadow Graſs*, makes the fineſt turf. It grows every where by way ſides, and on rich ſound commons. In ſome parts it is called *Suffolk Graſs*. See *Poa annua*.

8. *Sheep's Feſcue Graſs*, ſo much eſteemed for ſheep, and common on ſheep downs. See *Feſtuca ovina*.

9. *Purple Feſcue Graſs*, on ſheep downs, with fine bent and ſilver Hair Graſs. See *Feſtuca rubra*.

10. *Flote Feſcue Graſs*, a very fattening graſs when growing in water. See *Feſtuca fluitans*.

11. *Creſted Dog's-tail Graſs*, proper for parks, and for ſheep, and making a fine turf upon dry, ſandy or chalky ſoils. See *Cynoſurus criſtatus*.

Beſides theſe, Mr. Stillingfleet mentions, but does not figure—

12. *Yellow Oat Graſs*, likely to be fit for ſheep, and not uncommon in good meadows. See *Avena flaveſcens*.

13. *Perennial Darnel* or *Ray Graſs*, well known, and cultivated all over England. See *Lolium perenne*.

The above graſſes come into ear between the beginning of may and the middle of june, in the following order.

1. Annual meadow. 2. Meadow Fox-tail. 3. Vernal. 4. Great Meadow. 5. Narrow-leaved Meadow. 6. Creſted Dog-tail. 7. Sheep's Feſcue. 8. Purple Feſcue. 9. Fine Bent. 10. Marſh Bent. 11. Silver Hair. 12. Yellow Oat. 13. Flote Feſcue.

Mr. Curtis, who has beſtowed much attention, and tried many experiments on this ſubject, remarks that although it is an opinion which has long prevailed among many of the more enlightened agriculturiſts of the preſent age, that much of our meadow and paſture land may be rendered far more valuable than it is at preſent, by the introduction of ſome of our beſt graſſes; that although Stillingfleet and others have endeavoured to excite the huſbandman to collect and cultivate graſs-ſeeds, by writings fraught with the ſoundeſt reaſoning; and the Society for the encouragement of Arts, Manufactures and Commerce have attempted to attract him by the offers of well-directed premiums: yet hitherto they have not been productive of the deſired effect: Ray-graſs, with very few exceptions, continuing ſtill to be the only graſs whoſe ſeeds can be purchaſed for laying down land.

This Graſs not being ſuperior to all others, even inferior to ſome, and not being adapted to every ſoil and ſituation, Mr. Curtis has judiciouſly ſelected ſix of the beſt ſorts of Graſſes, adapted to ground of different quality. 1. Anthoxanthum vernum, or Sweet-ſcented Vernal-Graſs, figured in t. 1. The earlieſt of all our graſſes, next to Cynoſurus coeruleus: it will grow in any ſoil or ſituation; cattle are fond of it: but it is not ſo productive in point of crop as ſome others, and it yields the feweſt ſeeds.

2. Alopecurus pratenſis, or Meadow Fox-tail Graſs, figured in t. 2. Almoſt as early as the foregoing, much larger, and of quicker growth; conſequently much more productive; it ſhoots very rapidly after mowing, producing a very plentiful aftermath.

3. Poa pratenſis, or Smooth-ſtalked Meadow-Graſs, figured in t. 3. The foliage ſhoots early, but the flowering-ſtems are not produced ſo ſoon, by a week at leaſt, as the foregoing. Where early graſs paſturage is deſired, it cannot better be obtained than by a combination of theſe three; if crop be an object, this will have the preference.

Smooth-ſtalked Meadow-Graſs rather affects a dry ſituation, and hence keeps its verdure in long-continued dry weather better than moſt others: it will grow on the top of a wall, but more luxuriantly in a rich meadow: it has a root which creeps like Couch Graſs, and is almoſt as difficult to extirpate; it ought therefore to be introduced with caution where the paſturage is not intended to be permanent.

4. Poa trivialis or Rough ſtalked Meadow-Graſs, figured in t. 4. loves moiſture and a ſheltered ſituation; hence though few Graſſes are more productive or more adapted to hay or paſturage; it is tender, and liable to be injured by ſevere cold or exceſſive drought It is a principal graſs in that uncommonly productive meadow near Saliſbury, mentioned by Stillingfleet, and more particularly deſcribed in the Memoirs of the Bath Agricultural Society, vol. 1. p. 94.

The ſeeds of theſe two Graſſes are apt to be entangled with each other, as if cobwebs had been intermixed with them, which makes it difficult to diſperſe them evenly in ſowing.

5. Feſtuca pratenſis, or Meadow Feſcue Graſs, figured in t. 5. comes neareſt to Ray Graſs, to which however it is much ſuperior. It is larger, and more productive of foliage; is ſtrictly perennial, very hardy, and will thrive not only in very wet, but alſo in dry ground; it produces more ſeeds than any of the others, which are eaſily gathered, and readily grow. The flowering ſtems are a fortnight or three weeks later than Meadow Fox-tail; yet it cannot be conſidered as a late Graſs, for moſt of the Agroſtis genus and Meadow Cat's-tail (Phleum pratenſe) flower at leaſt three weeks later.—Feſtuca elatior is very ſimilar to this, but much coarſer.

6. Cynoſurus criſtatus, or Creſted Dog's-tail Graſs, figured in t. 6. grows in dry ſituations, and will not thrive in wet meadows. It flowers about the ſame time as Meadow Feſcue Graſs, and is not very productive of foliage: the ſtems alſo are wiry, and the roots penetrating to no great depth, in dry ſummers it becomes little better than an annual. Its ſeeds may eaſily be collected where the graſs is fed, for the ſtalks are never touched by cattle.

Of the above ſix Graſſes the ſecond and fourth are fitteſt for moiſt land: the firſt and fifth for land moiſt, or moderately dry: the third and ſixth for dry paſture.

The

The order of their flowering is as follows: 1 Vernal. 2. Meadow Fox-tail. 3. Smooth-ſtalked Meadow. 4. Rough-ſtalked Meadow. 5. Meadow Feſcue. 6. Creſted Dog's-tail.

To theſe ſix Graſſes we may add: 7. Avena elatior or Tall Oat Graſs. Early, very productive, and producing a plentiful aftermath; in excellence approaching to Alopecurus pratenſis, for which it may prove no bad ſubſtitute.

8. Avena flaveſcens or Yellow Oat Graſs; affecting dry ſoils, rather early, and tolerably productive.

9. Bromus mollis or Soft Brome Graſs: as an early Graſs it might perhaps be cultivated to advantage: but with other graſſes it ſheds the ſeed and withers, before the whole is ready for mowing.

10. Cynoſurus cæruleus or Blue Dog's-tail Graſs, is the earlieſt of all our graſſes, but not productive, or of a good quality.

11. Dactylis glomeratus, or Rough Cock's-foot Graſs, a rough coarſe Graſs, extremely hardy and productive, common in orchards and meadows, and rather early.

12. Feſtuca ovina or Sheep's Feſcue Graſs; native of dry elevated heaths and commons; unproductive, with hard and wiry foliage; a ſmall plant even in a rich moiſt ſoil.

13. Hordeum murinum, Wall Barley Graſs. Common by walls and the ſide of paths. H. maritimum or Squirrel-tail Graſs, among Hay is very injurious to horſes, by the awns or beards of the ears ſticking in their mouths.

14. Hordeum pratenſe or Meadow Barley Graſs; taller and more delicate; ſometimes forming great part of the crop in good meadows; neither early nor very productive.

15. Holcus lanatus, or Meadow Soft Graſs. Hardy and productive; flowering a month later than the Anthoxanthum; foliage ſoft and woolly.

16. Holcus mollis, or Creeping Soft Graſs. Grows well in ſandy ſoils, and bears drought.

17. Lolium perenne, or Ray Graſs, wiry with little foliage in upland paſtures; but in rich meadows its foliage is abundant and of rapid growth.

18. Poa annua, or Dwarf Meadow Graſs; perpetually flowering and ſeeding moſt rapidly, unleſs prevented by cold; growing in almoſt any ſoil and ſituation, but never acquiring any great height; its foliage tender and grateful to cattle, but liable to be killed by winter's froſt, and ſummer's drought.

19. Phleum pratenſe, or Meadow Cat's-tail Graſs, imported from America under the name of Timothy Graſs; in wet ſituations very productive, but coarſe and late; it has no excellence which Alopecurus pratenſis does not poſſeſs in an equal or ſuperior degree.

20. Triticum repens, Creeping Wheat Graſs, Quick, Quich or Couch Graſs. Too well known to farmers and gardeners as a moſt troubleſome weed. Its foliage is early.

Directions for ſowing Graſs Seeds.

Having gathered the ſpikes or panicles of any among the above graſſes which you are deſirous of cultivating, when they are ſufficiently ripe, and having threſhed or rubbed out the ſeeds; ſow them the end of auguſt or beginning of ſeptember, in rows nine or twelve inches apart, on a piece of clean ground, well dug, levelled and raked; cover the drills over lightly: if the weather be not uncommonly dry, the ſeeds will quickly vegetate, and the only attention they will require will be to weed them carefully: in a fortnight ſuch as are too thick may be thinned, and thoſe which are taken up tranſplanted, to make more rows of the ſame graſs.

During the firſt dry weather in the ſpring roll or tread the rows down, to fix the roots, which are generally looſened by the froſt, and weed them. As the ſpring advances, many of them will throw up their flowering ſtems, and ſome will continue to do ſo all the ſummer. As the ſeed ripens, gather it carefully, and ſow it in the autumn, at which time the roots of the original plants, which will now bear ſeparating, may be divided and tranſplanted; and thus by degrees a large plantation of theſe graſſes may be formed, particularly of the ſmooth-ſtalked Meadow-graſs, which creeps very much at the root.

While the ſeeds are thus increaſing, the ground to be laid down may be got in order, either by paring and burning, or by ploughing and harrowing, burning the roots of Quich and other weeds. Some cleanſing crop, as Potatoes, Turneps, Tares, &c. will contribute to bring the ground into order for this purpoſe, if otherwiſe not ſufficiently clean.

The land may now be ſown with Graſs ſeeds in the following proportion. Meadow Fox-tail and Meadow Feſcue, each one pint. Smooth-ſtalked and Rough-ſtalked Meadow, each half a pint. Creſted Dog's-tail and Vernal, each a quarter of a pint. Dutch or White Clover, and either Wild Red or Broad Clover, each half a pint. For wet or ſtrong land Creſted Dog's-tail and Smooth-ſtalked Meadow may be omitted, eſpecially the former.

Such a compoſition as this, ſown in the proportion of three buſhels to an acre, on a ſuitable ſoil, in a favourable ſituation, will in two years form a moſt excellent meadow; and being made up of hardy perennials, their places will not eaſily be uſurped by any noxious plants, which may be brought in by dung or any other means *.

GRATIOLA. *(Dimin. from gratia; on account of its ſuppoſed medicinal good qualities.)*

Lin. gen. n. 29. *Reich.* 30. *Schreb.* 36. *Gronov.* 6. *Gærtn. t.* 53. *Juſſ.* 121. Moniera. *Brown. jam. t.* 28. *f.* 3. *Ehret. t.* 14.

* Curtis's Practical Obſervations on Britiſh Graſſes, Lond. 1790. 8°.

Class. 2. 1. Diandria Monogynia.
Nat. order of *Personatæ.—Scrophulariæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, upright: *segments* awl-shaped, permanent.
COR. monopetalous, unequal: *tube* longer than the calyx: *border* four-parted, small; the upper segment broader, emarginate, reflex, the rest straight, equal.
STAM. *Filaments* four, awl-shaped, shorter than the corolla, the two lower shorter than the others, and barren; the two upper fastened to the tube of the petal. *Anthers* roundish.
PIST. *Germ* conic. *Style* straight, awl-shaped. *Stigma* two-lipped, after fecundation converging.
PER. *Capsule* ovate, acuminate, two-celled, two-valved.
SEEDS very many, small.

OBS. *The essence of the character consists in the two barren anthers.*

G. Monnieria *has anthers to all the filaments, and a capitate stigma.*—G. rotundifolia *has a compressed, roundish capsule, and two stamens.*—G. officinalis *has seven leaves to the calyx, the two outer patulous.*

ESSENTIAL CHARACTER.

Cal. seven-leaved, the two outer leaves patulous. *Cor.* irregular, reversed. *Stam.* two, barren. *Caps.* two-celled.

SPECIES.

1. Gratiola officinalis. *Officinal Gratiola*, or *Hedge-Hyssop, Water-Hyssop.*

Lin. syst. 64. *Reich.* 1. 48. *mant.* 174. *Retz. obs.* 4. 8. *n.* 6. *Pluk. alm. t.* 193. *f.* 2. *Lour. cochinch.* 22?
Leaves ovate-lanceolate subserrate much shorter than the internodes.]

6. Gratiola virginica.
Lin. spec. 25. *Syst.* 64. *Reich.* 1. 48. *mant.* 317. *Gærtn. fruct.* 1. 251. *Pluk. alm. t.* 193. *f.* 2. *Rhoed. mal.* 9. 165. *t.* 85.
Leaves lanceolate obtuse somewhat toothed.

7. Gratiola peruviana.
Lin. spec. 25. *Reich.* 1. 48. *Feuill. peruv.* 3. *t.* 47.
Flowers subsessile.

[8. Gratiola Lobelioides.
Retz. obs. 4. 7. *n.* 2.
G. rugosa. *Lour. cochinch.* 23.
Stem almost naked, stipuled, leaves oblong quite entire, panicle dichotomous, capsules subglobular.

9. Gratiola grandiflora. *Great-flowered Gratiola.*
Retz. obs. 4. 8. *n.* 3.
Stems decumbent, leaves ovate serrate, peduncles opposite, capsules subulate.

10. Gratiola veronicifolia. *Veronica-leaved Gratiola.*
Retz. obs. 4. 8. *n.* 4.
Ruellia antipoda. *Lin. mant.* 422. *Rumph. amb.* 5. 460. *t.* 170. *f.* 2.
Stem creeping, leaves ovate-lanceolate sharply serrate, flowers terminating opposite.

11. Gratiola oppositifolia.
Retz. obs 8. *n.* 4.
Stem ascending, leaves lanceolate serrate, peduncles opposite to the leaves.

12. Gratiola stricta.
Lour. cochinch. 23.
Leaves ovate, spike long terminating.

DESCRIPTIONS, &c.

1. *Root* perennial, creeping, thick, fleshy, with many slender fibres. *Stalks* several, upright, a foot or more in height, smooth, jointed. *Leaves* opposite, sessile, pointed, bright green, smooth, two inches long, and two lines or more in breadth, with a few small serratures towards the end. *Flowers* solitary, axillary, upright, on peduncles half an inch long, appearing in june or july, and continuing to august: calyx usually seven-cleft: corolla sharped like that of the Foxglove; but small and of a pale yellowish colour, or pale purple with red streaks: sometimes white: the throat is hairy.

Native of the South of Europe, in pastures, usually such as are moist. Common in many parts of Switzerland, Carniola, Austria, in the Palatinate, Silesia, France, about Turin, Padua, and in other parts of Italy.

It has a strong bitter nauseous taste, and is much recommended by several eminent medical writers in dropsical cases. It is a powerful cathartic, but is said generally to occasion vomiting.

On account of its bitterness, cattle reject it; insomuch that Haller assures us there are meadows about Yverdun entirely useless from the abundance of this plant.

It was cultivated in our gardens as early at least as 1568 [a].

2. *Root* jointed, creeping, with small fibres. *Stalk* herbaceous, inclined to be simple, round, leafy, smooth, somewhat erect, declining at bottom. *Leaves* subsessile, opposite, oblong or obovate, entire, smooth, nerveless, somewhat succulent. *Peduncles* longer than the leaves, filiform, solitary, axillary, one-flowered. *Calyx* seven-leaved; the three outer leaflets subcordate, acuminate, converging, the two inner linear, acute, pale, when the corolla falls embracing the germ, the two outmost lower, lanceolate, spreading. *Corolla* blue, inclined to bell-shape, a little flatted, five-cleft; the divisions nearly equal: the three upper ovate, spreading; the two lower converging, somewhat bent down. *Filaments* two, shorter by half than the other two: *anthers* ovate, blue [b].

This small, creeping plant sticks very close to the ground, and casts a few slender fibres from every joint, as it creeps. The whole plant seldom exceeds seven or eight inches in length, but it generally grows in beds, and spreads thick upon the ground, throwing out a few simple side-branches, which give it a pretty appearance when it flowers, and make it exceedingly remarkable [c].

Native both of the East and West Indies, and the South Sea islands: in low moist soils. It was introduced in 1772, by Mons. Richard; and flowers from july to september [d].

The name of *Monnieria* was given to this plant in honour of Dr. De Monier by Mons. Bernard de Jussieu, who raised it in the botanic garden at Paris.

3. Native of Jamaica [e].

4. Stems a finger high, quadrangular, smooth, creeping at the base. Leaves opposite, sessile, obtuse, smooth, with one or two obscure serratures. Peduncles axillary, solitary, naked, alternate, one-flowered, longer than the leaves. Calyx five-parted. Stamens two. Capsules compressed, roundish.

Native of Malabar, in sandy grounds [f].

[a] Hort. kew. from Turner's herbal, part 3. fol. 33.
[b] Swartz. obs. [c] Browne. [d] Hort. kew. [e] Swartz.
[f] Linn. mant.

5. Annual. Stem filiform, upright, ſmooth, a foot high. Leaves oppoſite, ſeſſile, ſmooth, with a ſerrature or two on the loweſt. Peduncles axillary, alternate, ſolitary, one flowered, ſeveral times longer than the leaves. Calyx very ſmall. Corolla much larger than the leaves, ringent[a]. Leaves uſually ovate, eſpecially the lower ones. The proportion of theſe to the internodes gives no conſtant character[b].

Native of the Rice-grounds of Tranquebar, in the Eaſt Indies.

6. Stem procumbent, varying much in ſize. Leaves oppoſite, ſeſſile, ſerrate towards the tip; ſometimes trifid. Peduncles axillary, one-flowered. Capſule twice as long as the calyx, with the ſtyle permanent[c]. Calyx five-parted, with two acceſſory leaflets at the baſe. Capſule ſubglobular, with a furrow on each ſide; the valves often biſid at the tip. Partition ſimple, parallel to the valves, and inſerted into their future[b].

The corolla is white, and the flowers not followed by ſeeds in England. It grows naturally in North America, in moiſt places, where it riſes more than a foot high, but here not more than eight inches. [It is alſo native of Malabar.

Mr. Miller cultivated it in 1759.]

7. This plant grew here about nine inches high, with a weak ſtalk. Leaves oppoſite, ſerrate, three quarters of an inch long, and half an inch broad. The flowers come out ſingle on each ſide the ſtalk, they are white and much ſmaller than thoſe of the common ſort. Mr. Miller received the ſeeds from Carthagena in New Spain, where it was found in places where there had been ſtanding waters, which were then dried up. [He cultivated it in 1759; but the ſeeds not ripening it was ſoon loſt.

8. Roots numerous, in bundles, ſhort, ſimple. Stalk ſimple, upright, round, having an obſcure, broad furrow on each ſide, ſlightly ſtreaked, ſmooth, with five ſtipuled joints, a foot high. Leaves above the ſecond or third pair oppoſite, ſeſſile, upright, with the tips a little bowed back, acute, ſlightly ſtreaked, ſmooth on both ſides, an inch long, ſometimes coloured at the baſe, eſpecially underneath, ſtipules two oppoſite, growing cloſe at the joints, ſeſſile, half ovate, preſſed cloſe, acute, quite entire, ſmooth ſomewhat fleſhy, greener than the ſtalk and leaves, ſmall. Panicle terminating, lax, thin, with peduncles moſtly ſimple, alternate, remote, round, ſmooth, or ſometimes with a few ſcattered hairs, ſlender, nearly equal with bractes at the baſe, reddiſh green. Pedicels longer than the flower. Bractes like the ſtipules, only a little narrower, ſmall. Flowers inferior. Calyx bell-ſhaped, ſmooth, ſmaller ſhorter than the tube of the corolla; ſegments preſſed cloſe, oblong, unequal, the two upper ones a little larger, more rounded at the tip. Corolla, tube ſtreaked with a darker colour: border bell-ſhaped, the upper ſegment ſcarcely aſcending, obcordate, flattiſh, ſhorter than the others, blue, the ſide ones ſtraight, obliquely retuſe at the ends, a little longer than the upper one, and of the ſame colour, the lower one ſpreading, obcordate, flattiſh, adorned with a white heart-ſhaped ſpot and a few blue dots, and twice as large as the others; throat naked, a little ſtatted. Filaments two remote, within the throat, growing to the tube upright at the baſe, a little twiſted at the tips, ſmooth, ſhort, browniſh-green, having a beard of ſhort ſilky white hairs at the baſe: anthers connate, each double and before flowering time diſtinct; each part oblong, upright, ſharp at both ends, yellow two-celled: between theſe are the rudiments of two other ſtamens cloſe together, flat, running ſtraight down, very minutely bearded with ſnow-white hairs, ſometimes hardly diſtinguiſhable. Germ ſuperior, ovate, ſmooth, with a ſmall furrow on each ſide. Stigma below the anthers, peltate, ſuborbiculate, large, a little concave, ſmooth, entire in front, but having two notches behind; between the notches are twin callous ſtraight toothlets; cloſe to each tooth a white hardiſh callous. Capſule ſmooth, with a ſmall furrow, twice as long as the calyx: ſeeds oblong, ſharp at both ends, a little wrinkled faſtened to a two-parted receptacle. Very common near Tranquebar, in rice fields[d].

9. Stems biſid, angular, ſmooth. Leaves oppoſite, ſerrate, often crenate, ſmooth. Flowers large in proportion to the other parts. Capſules long.

Native of Tranquebar, Madras, Siam, Malacca, in moiſt fat ſoils.

10. Stems angular, diffuſed, procumbent. Leaves oppoſite, ſeſſile. Flowers ſmall, deep blue, bracted and peduncled. Calyx five-cleft, linear. Capſule ſubulate.—With the foregoing.

11. Stems ſeldom upright, quadrangular, ſtreaked. Leaves naked, the lower ones oppoſite; the axils uſually branch-bearing: the upper ones alternate. Capſules long, ſubulate.

Native of Tranquebar in rice-grounds and moiſt places[a].

12. Stem ſoffruticoſe, quite ſimple, erect, a foot and half high. Leaves acuminate, ſubſerrate, flat, ſmooth, oppoſite. Flowers white dotted with red, ſeſſile, in a ſimple erect ſpike. Calyx none except a triple bracte under the flower. Corolla with a long ſlender angular tube, and a two-lipped, five-cleft ſpreading border. Capſule oblong, acuminate, ſinuate in the middle, compreſſed, two-ſeeded.

Native of Cochinchina[e].]

PROPAGATION AND CULTURE.

The firſt and fifth ſorts are eaſily propagated by parting the roots in autumn, when the ſtalks decay; the plants ſhould have a moiſt ſoil and a ſhady ſituation, for in dry ground they often decay in ſummer, unleſs they are plentifully watered. [The other ſorts are natives of hot climates, and little known in Europe.

GRATIOLA. See *Hottonia indica*, *Lindernia*, *Mimulus*.

GRATIOLÆ AFFINIS. See *Capraria*, *Dianthera*, *Juſticia*.]

GRAVEL and Graſs are the glory of Engliſh gardens, and things in which we excel all other nations.

There are different ſorts of Gravel, but for thoſe who can conveniently have it, I approve of that Gravel on Blackheath, as preferable to moſt that we have in England; it conſiſting of ſmooth even pebbles, which, when mixed with a due quantity of loam, will bind exceeding cloſe, and look very beautiful, and continue handſome longer than any other ſort of Gravel which I have yet ſeen.

Some recommend a ſort of iron-mould Gravel, or Gravel with a little binding loam amongſt it, than which nothing, they ſay, binds better when it is dry; but in wet weather it is apt to ſtick to the heels of one's ſhoes, and will never appear handſome.

Sometimes loam is mixed with Gravel that is over ſandy or ſharp, which muſt be very well blended together, and let lie in heaps, after which it will bind like a rock.

There are many kinds of Gravel which do not bind, and thereby cauſe a continual trouble of rolling, to little or no purpoſe; as for ſuch,

If the Gravel be looſe or ſandy, you ſhould take one load of ſtrong loam, to two or three of Gravel, and ſo caſt them well together, and turn this mixture over three or four times, that they may be well blended together; if this is done in proper proportion, it will bind well, and not ſtick to the feet in wet weather.

There are many different opinions about the choice of Gravel: ſome are for having the Gravel as white as poſſible, and in order to make the walks more ſo, they roll them well with ſtone rollers, which are often hewn by the maſons, that they may add a whiteneſs to the walks; but this renders it very troubleſome to the eyes, by reflecting the rays of light ſo ſtrongly, therefore this ſhould ever be avoided; and ſuch Gravel as will lie ſmooth, and reflect the leaſt, ſhould be preferred.

Some ſcreen the Gravel too fine, which is an error; for if it be caſt into a round heap, and the great ſtones only raked off, it will be the better.

Some are apt to lay Gravel-walks too round, but this is likewiſe an error, becauſe they are not ſo good to walk upon, and beſides, it makes them look narrow; one inch riſe is enough in a crown for a walk of five

[a] Linn. mant. [b] Retz. [c] Linn. mant. [d] Koenig in Retz. [e] Loureiro.
[b] Gaertner.

feet;

feet; and it will be ſufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each ſide; if fifteen feet three inches; twenty feet, four; and ſo in proportion.

For the depth of Gravel-walks, ſix or eight inches may do well enough, but a foot thickneſs will be ſufficient for any; but then there ſhould always be a depth of rubbiſh laid under the Gravel, eſpecially if the ground is wet; in which caſe there cannot be too much care to fill the bottom of the walks with large ſtones, flints, brick rubbiſh, chalk, or any other materials which can be beſt procured, which will drain off the moiſture from the gravel, and prevent its being poachy in wet weather; but as it may be difficult in ſome places to procure a ſufficient quantity of theſe materials to lay in the bottom of the walks, ſo there may be a bed of Heath, or Furze, which ever can be procured at the leaſt expenſe, laid under the Gravel to keep it dry; and if either of theſe are uſed green, they will lie a long time, as they will be covered from air, and theſe will prevent the gravel from getting down into the clay, and will always keep the gravel dry; and where there is not this precaution in the firſt laying of the gravel upon clay, the water being detained by the clay, will cauſe the gravel to be poachy whenever there is much rain.

In making of gravel-walks, there muſt be great regard had to the level of the ground, ſo as to lay the walks with eaſy deſcents towards the low parts of the ground, that the wet may be drained off eaſily; for when this is omitted, the water will lie upon the walks a conſiderable time after hard rains, which will render them unfit for uſe, eſpecially when the ground is naturally wet or ſtrong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have ſink-ſtones laid by the ſides of the walks, at convenient diſtances, to let off the wet: and where the ground is naturally dry, that the water will ſoon ſoak away, the drains of the ſink-ſtones may be contrived ſo as to convey the water in peſſpools, from which the water will ſoak away in a ſhort time; but in wet land there ſhould be under-ground drains, to convey the wet off, either into ponds, ditches, or the neareſt place to receive it; for where this is not well provided for, the walks will never be ſo handſome or ſo uſeful.

The month of march is the propereſt time for laying gravel; it is not prudent to do it ſooner, or to lay walks in any of the winter months before that time.

Some indeed turn up gravel-walks in ridges in december, in order to kill the weeds; but this is very wrong, for beſides that it deprives them of the benefit of them all the winter, it does not anſwer the end for which it is done, but rather the contrary; for though it does kill the weeds for the preſent, yet it adds a fertility to them, as to the great future increaſe of both them and graſs.

If conſtant rolling them after the rains and froſt will not effectually kill the weeds and moſs, you ſhould turn the walks in march, and lay them down at the ſame time.

In order to deſtroy worms that ſpoil the beauty of gravel, or graſs-walks, ſome recommended the watering them well with water in which Walnut-tree leaves have been ſteeped, and made very bitter, eſpecially thoſe places moſt annoyed with them; and this they ſay, as ſoon as it reaches them, will make them come out haſtily, ſo that they may be gathered; but if, in the firſt laying of the walks, there is a good bed of lime rubbiſh laid in the bottom, it is the moſt effectual method to keep out the worms, for they do not care to harbour near lime.

[GREEK VALERIAN. See *Polemonium*.

GREENHOUSE and CONSERVATORY.

Theſe are buildings erected on the beſt principles (*ſee the plans*) for protecting and preſerving ſuch ſort of plants as are too tender to live in the open air.

Greenhouſe.

The Greenhouſe was originally a room in a garden, not far from the houſe, facing the ſouth, and having large windows from top to bottom, built for the reception of Oranges, Myrtles, and a few other plants which were brought from temperate climates. This building had no flues or contrivances of any ſort for increaſing the natural heat, but the air of the room was warmed merely by the ſun.

A greater variety of curious exotic plants having been introduced into the Engliſh gardens ſoon after the middle, and towards the end of the laſt century, flues were added to the Greenhouſe, and many improvements in the ſtructure and contrivance of it were adopted.]

As to the length of the greenhouſe, ſays Mr. Miller, it muſt be proportioned to the number of plants it is to contain, or the fancy of the owner; but the depth ſhould never be greater than the height in the clear, which in ſmall or middling houſes may be ſixteen or eighteen feet, but for large ones from twenty to twenty-four feet is a good proportion; for if the greenhouſe be long and too narrow, it will have a bad appearance both within and without, nor will it contain ſo many plants, if proper room be allowed for paſſing in front, and at the back of the ſtands on which the plants are placed; and on the other hand if the depth of the greenhouſe be more than twenty-four feet, there muſt be more rows of plants placed to fill the houſe, than can with conveniency be reached in watering and cleaning; nor are houſes of too great depth ſo proper for keeping of plants as thoſe of moderate ſize.

The windows in front ſhould extend from about one foot and a half above the pavement, to within the ſame diſtance of the cieling, which will admit of a cornice round the building over the heads of the windows. As it is neceſſary to have theſe windows ſo long, it will be impoſſible to make them in proportion as to their breadth; for if the ſaſhes be more than ſeven or ſeven feet and a half broad, they will be troubleſome to move up and down, and their weight will occaſion them to decay very quickly. The piers between the windows ſhould be as narrow as is conſiſtent with their neceſſary ſtrength to ſupport the building; for which reaſon ſtone is preferable, or hard well-burnt bricks. If theſe piers are made of ſtone, they would be two feet and a half in diameter, worked as columns cylindrical, whereby the rays of the ſun will not be obſtructed ſo much as if they were ſquare; but if they are built of bricks, it will be proper to make them three feet in front: and they may be ſloped off towards the inſide to admit the ſun.

If a houſe for tools, &c. be erected at the back of the greenhouſe, the back wall need not be more than two bricks and a half in thickneſs; but if not, it muſt be three bricks or three bricks and a half thick, to keep out the froſt.

The floor of the greenhouſe may be laid with Bremen ſquares, Purbeck ſtone, or broad tiles; and muſt be raiſed two feet above the ground, where the ſoil is dry; but if the ſituation be moiſt and ſpringy, the floor ſhould be raiſed at leaſt three feet above the ſurface; and if the whole be arched with low brick arches under the floor, it will be of great ſervice in preventing the damps riſing in winter, which are often very hurtful to the plants, eſpecially in great thaws, when the air is often too cold to be admitted into the houſe, to take off the damps. Under the floor, about one foot from the front, a flue one foot in width, and two feet in depth may be carried the whole length of the houſe, which may be returned againſt the back wall, and carried up in proper funnels adjoining to the tool houſe, three times over each other, by which the ſmoke may paſs off. The fire-place may be at one end of the houſe, and the door at which the fuel is put in, as alſo the aſh-grate, may be contrived to open into the tool houſe, ſo that it may be quite hid from ſight and be dry; the fuel alſo may be laid in the ſame ſhed, and thus will always be ready for uſe.

The wall on the back part of the houſe ſhould be either laid over with ſtucco, or plaſtered with mortar and white-waſhed, to keep out the froſt, which will penetrate through the walls, eſpecially when it is attended with a ſtrong wind.

To prevent froſt from penetrating through the roof reeds heath or furze ſhould be laid between the cieling

and the tiles; and care ſhould be taken in framing the joints that the weight may not lie upon the cieling; for they ſhould be laid a foot thick at leaſt, as ſmooth as poſſible, and faſtened down well with laths to prevent their riſing, and then covered over with a coat of lime and hair, which will keep out the air, and alſo prevent mice and other vermin from harbouring in them, which, if left uncovered, they would certainly do.

In the greenhouſe there ſhould be treſſels, which may be moved in and out, upon which rows of planks ſhould be fixed, ſo as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants may be ſo ſituated, as not to interfere with each other. The loweſt row of plants, or forwardeſt towards the windows, ſhould be placed about four feet from them, that there may be a convenient breadth left next the glaſſes to walk in front; and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner that the heads of the ſecond row ſhould be entirely advanced above the firſt, the ſtems only being hid; and at the back of the houſe there ſhould be allowed a ſpace of at leaſt five feet, for the conveniency of watering the plants, and to admit a current of air round them, that the damps occaſioned by the perſpiration of the plants may be the better diſſipated, which by being pent in too cloſely often occaſions a mouldineſs upon the tender ſhoots and leaves, and when the houſe is cloſe ſhut up, this ſtagnating rancid vapour is often very deſtructive to the plants; for which reaſon alſo they ſhould never be crowded too cloſe to each other, nor ſhould ſucculent plants ever be placed among them.

[The plants are put into the greenhouſe in octoher, or as ſoon as the morning and evening froſts come on. In this ſituation they remain till the end of may or the middle of june, according to the ſeaſon, when they are removed to the place where they are to ſtand through the ſummer Much of their growth and ſucceſs depends upon the choice of a ſheltered and convenient ſituation for them at this ſeaſon: it muſt not be expoſed to the meridian ſun, nor to the weſt or north winds, both which are extremely hurtful to them when firſt expoſed, and again in the autumn Here they muſt be refreſhed with frequent waterings in dry weather at leaſt three times a week.

Before the plants are removed out of the greenhouſe it is neceſſary to ſhift at leaſt all the ſmall plants; that is, to take them out of their pots, to cut off part of their roots round the ball of earth, and to put them again into the ſame pot if the plant is not in a healthy ſtate; or, if it is, into one a ſize larger; ſhortening the irregular ſide branches as they may require, and tying them up neatly.

The mould into which the plants are to be ſhifted is of conſiderable importance. The beſt is to be obtained from commons where ſheep and cattle paſture, particularly in low places, where the fineſt graſs grows, and the ſoil is deepeſt. A foot of the top ſoil with the turf may be taken off, and if it be a ſandy or hazel loam it will do alone; but if it be a ſtrong loam, ſome ſand and black peaty or mooriſh ſoil ſhould be added. Such ſoils laid in a heap, for at leaſt ſix of the winter months, and frequently turned over, will ſuit moſt greenhouſe plants.

Aloes, Meſembryanthemums, Ixias and ſuch Liliaceous plants in general as are inhabitants of Exotic houſes and glaſs caſes, require a ſoil which is a degree lighter, and which will not retain the water, but let it paſs readily; and a little coal aſhes at the bottom of each pot may be uſeful for this purpoſe.

The great number of Ericas or Heaths and other beautiful plants from the Cape of Good Hope, from America and Botany Bay delight and flouriſh in that ſort of earth which comes neareſt to their native ſoil. Thus the Heaths like a black peat or mooriſh ſoil; and the others that which is made a degree ſtronger with loam.

A Plan and Elevation of the greenhouſe, according to the lateſt modern improvements is given on the plate which accompanies this article, from a drawing made by Mr. Malcolm; in which

A is the Elevation.

B The Section of the weſt end.

CC are the fire-places in the ground plan.

DD the funnels of the Chimney.

E is the back wall.

FF the inſide of the greenhouſe, where the Stages are to be erected.

GG are the Flues running under the footpath; with the manner in which they divide and paſs into the funnels of the chimney.

H is the front wall.

The dimenſions of the whole and all the parts are laid down exactly by a ſcale. The pediments, pilaſters, columns, pateras, and other ornamental parts are to be of ſtone. On the top of the centre of each of the three end windows on each ſide of the pediment there ſhould be a key-ſtone, with a head or other device; and from the pediment over each of the three windows there ſhould be a feſtoon of flowers tied up over the centre of the windows. The pateras in the weſt end ſhould be ornamented.

Conſervatory.

Greenhouſe or Conſervatory have been generally conſidered as ſynonimous terms for a houſe of a certain conſtruction, deſtined, to the preſervation of exotic plants through the winter. Their eſſential difference is this. In the greenhouſe, the trees and plants are either in tubs or pots; and are placed on ſtands and ſtages through the winter, till they are removed into ſome ſheltered ſituation abroad for the ſummer. In the Conſervatory, the ground plan is laid out in beds and borders, made up of the beſt compoſitions of ſoils that can be procured, three or four feet in depth. In theſe the trees and plants, taken out of their tubs or pots, are regularly planted, in the ſame manner as hardy plants are in the open air. Inſtead of taking out the plants in ſummer, as in the greenhouſe, the whole of the glaſs roof is taken off, and the plants are thus expoſed to the open air: and at the approach of autumn froſts the lights are again put on, and remain ſo till the may or june following.

It is evident that the building here called a Conſervatory may alſo be uſed as a greenhouſe at the diſcretion of the owner, by introducing ſtages inſtead of beds; and in that caſe the glaſs roof may be fixed.

On each ſide of the Conſervatory, in the plan is a hot-houſe or ſtove, and a retiring room; and at the back of the whole is a houſe for a Gardener, and ſheds or offices for tools or other utenſils, for drying plants, ſeeds, &c. &c.

One of the hot-houſes is furniſhed with a ſtage, and is appropriated to ſuch plants as come from Africa, New South Wales, and the like climates; and is called a Dry Stove. The other has a bark-bed, for plants from the Eaſt and Weſt Indies, or other hot climates, and which require a tan heat to plunge the pots in, and a greater degree of fire to keep up the heat of the ſtove to within a few degrees of their native climate; for it would be both imprudent and impoſſible to keep up the heat at all times to that of Jamaica. This is called a bark Stove. See STOVES.

One of the retiring rooms may be fitted up as an Aviary; or they may both be omitted at the pleaſure of the owner.

Explanation of the Plate containing the plan and elevation of a Conſervatory, with two Stoves, retiring rooms, Gardener's Houſe, and Offices for Utenſils, &c.

I I Area of the two Stoves.

The whole and all the parts are accurately drawn to a ſcale, which makes it unneceſſary to give the dimenſions.

ſions. The buildings given in this plan, and which have been frequently executed by Mr. Malcolm, who furniſhed the drawings and deſcriptions for this work, are all in the ſame line.]

In Mr. Miller's plan, the Greenhouſe or Conſervatory is placed exactly fronting the ſouth: one of the wings or ſtoves facing the ſouth-eaſt, and the other the ſouth-weſt; ſo that from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it is conſtantly reflected from one part to the other, and the cold winds are alſo kept off from the front of the centre building. In the area many of the more tender exotic plants may be placed in the ſummer ſeaſon, and in the ſpring, before the plants can be ſet out, the beds and borders of this area may be full of Anemonies, Ranunculuſes, early Tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground, by the time the plants are taken out. In the centre of this area may be a ſmall baſon of water which will be very convenient for watering the plants, not only on account of its nearneſs, but becauſe the water will be ſoftened and warmed by the reflection from the glaſſes.

The wing facing the ſouth-eaſt ſhould always be preferred for the warmeſt or bark ſtove, becauſe the ſun, at its firſt appearance in the morning, ſhining directly upon the glaſſes, and warming the air of the houſe, gives new life to the plants, after the long nights of the winter ſeaſon.

In theſe buildings, if there are not ſheds running behind them their whole length, the walls ſhould not be leſs than three bricks thick; and if they are even more it will be better, becauſe where the walls are thin and expoſed to the open air, the cold will penetrate, and when the fires are made, the heat will come out through the walls, ſo that it will require a larger quantity of fuel, to maintain a proper temperature of warmth in the houſe; and in general the cloſer and better theſe houſes are built, the leſs fuel will be required to warm them; ſo that the firſt expenſe in building them properly will be the cheapeſt, when after the expenſe of fires is taken into conſideration.

Beſides theſe buildings, it will be proper to have deep hot-bed frames, ſuch as are commonly uſed to raiſe large annuals in the ſpring, into which may be ſet pots of ſuch plants as come from Carolina, Virginia, &c. whilſt the plants are too ſmall to bear the open air; as alſo many other ſorts from Spain, and the other ſouthern countries of Europe, which require only to be ſcreened from the violence of froſts, and ſhould have as much free air as poſſible in mild weather; which can be no better effected than in one of theſe frames, where the glaſſes may be taken off every day when the weather will permit, and put on every night; and in hard froſts the glaſſes may be covered with mats, ſtraws, peas-haulm, or the like: to prevent the roots of the plants from being frozen. If theſe pits be ſunk a foot or more below the ſurface of the ground, it will be better, provided the ground be dry. The ſides of the frame ſhould be built with brick, and a curb of wood laid round on the top of the wall, into which the gutters whereon the glaſſes ſlide may be laid: the back wall may be four feet high, and two bricks and a half thick the front one foot and a half; the width of the inſide of the frame about ſix feet, and the length in proportion to the number of plants to be contained in it.

GREENWEED or GREENWOOD. See *Genista*.

GREGOTA. See *Myrtus*.

GREWIA. *(So named by Linnæus, in honour of Nehemiah Grew, M. D. F. R. S. the famous author of the Anatomy of Vegetables, 1682. fol.)*

DESCRIPTIONS, &c.

1. This will grow to the height of ten or twelve feet, and has a ſtem and branches very like thoſe of the ſmall-leaved Elm, the bark being ſmooth, and of the ſame colour as that of Elm when young; the leaves are alſo very like thoſe of the Elm, and fall off in winter: the flowers are produced ſingly along the young branches from the axils, and are of a bright purple colour; they appear towards the end of july, and continue through auguſt to the beginning of ſeptember, but are never ſucceeded by fruit in this country.

[It appears from Plukenet that it was cultivated in 1792, in the Royal Garden at Hampton Court.

2. This is a branching ſhrub; the branches ſlender, ſmooth, aſh-coloured. Leaves petioled, alternate, ſcattered, unequally and bluntly tooth-crenate, veined, very ſmooth above, ſcarcely pubeſcent beneath; hairs ſtellate viſible only with a magnifier. Petiole filiform, the length of the leaves.[a] Peduncle filiform, a little longer than the leaves, and from the ſame bud. Bractes in pairs, on the middle of the peduncle, deciduous. Calycine leaflets linear, obtuſe, villoſe, ſmooth within, coloured. Petals linear, ſhorter than the calyx.—Allied to the foregoing, but of a looſer habit, with the leaves hanging down like thoſe of Populus tremula, having ſtellate hairs beneath: the flowers are a little ſmaller[b].

3. Allied to the firſt ſort. It is a tree of middling ſize. Leaves ſerrate, petioled. Peduncles from the axils, tomentoſe, trifid, three-flowered[b]. Berry ſubglobular, depreſſed, becoming obtuſely four-cornered in drying, ſucculent; the ſkin when freſh ſaffron-coloured, viſible, fleſh pulpy, fugacious, ſtones hard, like grape-ſtones, having a deep furrow on the back, two-celled. Seed one in each cell, that is, eight in a whole berry, obovate, compreſſed like a lens, ſomewhat livid or bay-coloured[c].

Native of the Eaſt Indies. Introduced in 1767, by Mr. William Malcolm. It flowers in july and auguſt[d].

4. Branches with a purple bark dotted with white. Leaves on very ſhort petioles, blunt, ſerrate on the outſide, from two to three inches long. Stipules awl-ſhaped pubeſcent. Peduncles axillary, ſolitary, four times as long as the petiole. Pedicels almoſt the length of the petioles. It differs from the next in having longer leaves, quite entire and without glands at the baſe, and three-flowered long peduncles.

Native of the Eaſt Indies, where it was obſerved by Koenig.

5. Branches ſomewhat rugged. Leaves acute, ſmooth, crenate, the three or five notches next the baſe glandular. Petiole ſhort. Flowers axillary, on very ſhort peduncles.

Native of the Iſle of France.

6. Branches ſoft with hairs, eſpecially at top. Leaves on very ſhort petioles, acuminate, more villoſe underneath, unequally and ſharply ſerrate, an inch and half in length. Stipules briſtle-ſhaped, the length of the petioles. Peduncles axillary, in threes; ſometimes ſolitary. Flowers ſubſeſſile, with a three-leaved lanceolate involucre. Petals very ſhort, oblong, ciliate.

Found by Koenig on the tops of mountains in the Eaſt Indies.

7. Leaves unequally and bluntly ſerrate, the upper ſurface even, nerved and veined, the lower hoary. Peduncles axillary, often ſolitary, three-flowered; pedicels angular[e].

8. A tree with the branches ſcarcely tomentoſe. Stipules lanceolate. Leaves alternate, petioled, roundiſh, ſharpiſh, five-nerved, ſcarcely lobed, tomentoſe underneath, the ſize of Apple-leaves. Petioles round, tomentoſe, one fifth of the length of the leaves. Peduncles axillary, uſually in fours, trifid, three-flowered, half the length of the leaves. Petals not bigger than the calyx. Berries ſmall, red, acid.

Native of Suratte[f].

9. Branches ſmooth, with a brown bark very minutely dotted with aſh-colour, the younger ones ſubvilloſe. Leaves a hand breadth and more, nerved and veined, one lobe of the baſe a little ſhorter than the other, bluntly ſerrate; the ſerratures almoſt equal. Petioles powdered at the tip, ſcarcely thickened. Stipules half-cordate, acuminate, ſhorter than the petiole. Peduncles axillary, two or three together, three-flowered. Involucre three-leaved; leaflets lanceolate, obtuſe, concave, the length of the pedicels. Calyx tomentoſe on the outſide, ſmooth within, coloured. Germ on a ſhort pedicel. Fruit two-grained.

Native of the Eaſt Indies[g].

10. The difference by which it may be known from the other ſpecies is with difficulty made out[h]. It is diſtinct by having no ſcales to the petals, the germ ſeſſile, and the ſtones or nuts not two-celled[i]. The berry is obtuſely four-cornered, depreſſed, ſcabrous on all ſides with minute briſtles: the ſtones are ovate-acuminate, turgidly lens-ſhaped, wrinkled and rough with very ſmall tubercles, one-celled, thick and hard. Seeds ſolitary, and four in the whole berry, obovate, remarkably tapering downwards, ſomewhat livid[k].

Native of the iſlands of Tongatabu and Huaheine in the South Seas[l].

11. Stem ſhrubby. All parts of the plant very ſoft with nap. Leaves alternate, ſometimes angular towards the tip; ſerratures bluntiſh, remote, unequal. Petioles very ſhort. Stipules briſtle-ſhaped, deciduous. Peduncles the length of the petioles. Flowers ſmaller than in G. aſiatica[m].

12. A ſhrub. Leaves petioled, tapering to both ends, obtuſe, ſmooth above, hoary and veined underneath. Peduncles three or more, tomentoſe, ſhort. Flowers upright. Calyx five-toothed, tomentoſe. Petals tomentoſe, upright, yellow, bifid at the tip. Filaments much bearded at the baſe, the other part ſmooth: anthers long, yellow. Stigma capitate, emarginate[n].

Native of the Eaſt Indies. Introduced in 1779, by John Gerard Koenig, M. D.

13. A tree. Leaves alternate, acuminate, very ſlightly crenate, nerved, petioled, roughiſh. Flowers terminating. Calyxes tomentoſe[o].

Native of the Eaſt Indies.]

PROPAGATION AND CULTURE.

1. The common Grewia may be propagated from cuttings or layers; the cuttings ſhould be taken off, and planted in april, before the buds ſwell, for they do not ſucceed well after; theſe cuttings ſhould be planted in ſmall pots filled with loamy earth, and the pots ſhould be plunged into a moderate hot-bed of tanners bark, where, if they are duly watered, and in the heat of the day ſhaded from the ſun, they will take good root in about two months, and may then be gradually inured to bear the open air, into which they ſhould be removed in june, and placed in a ſheltered ſituation, where they may remain till autumn, when they muſt be removed into the green-houſe; the beſt time to lay down the layers of this plant is in the ſpring, before the buds come out, and theſe will be rooted by the ſame time the following year, when they may be cut off from the old plants, and planted each into a ſeparate pot filled with a ſoft loamy ſoil.

The beſt time to remove or tranſplant this plant is, either in the ſpring, juſt before the buds begin to ſwell, or in autumn, when the leaves begin to drop; for in ſummer, when the plants are in full leaf, it will be very improper to diſturb them.

In winter theſe plants ſhould be placed in the green-houſe, for they are too tender to live abroad in England; but they ſhould have as much free air as poſſible in mild weather; for they only require to be protected from froſt, and after their leaves are fallen, they will require very moderate watering; but in ſummer they ſhould be conſtantly watered three or four times a week in dry weather, and placed in a ſheltered ſituation, with other hardy green-houſe plants, where they will add to the variety.

The other ſorts being tender, will not live through the winter in England, unleſs they are placed in a warm

[a] Vahl. [b] Linn. ſyſt. and zeyl. [c] Gærtner. [d] Hort. kew. [e] Vahl. [f] Linn. mant. [g] Vahl. [h] Linn. ſuppl. [i] Joſſieu. [k] Gærtner. [l] Forſter. [m] Vahl. [n] Linn. ſuppl. [o] Linn. zeyl.

ſtove; nor do thoſe plants thrive well, which are placed on ſhelves in the dry ſtove; therefore the only method to have them ſucceed, is to place them in the bark-bed in the tan-ſtove. In ſummer theſe plants require a good ſhare of free air to be admitted to them, and ſhould have water three or four times a week in warm weather; but in winter they muſt be ſparingly watered, and require to be kept warm.

SEEDS. *Nucleus* ſcored with eight furrows.

ESSENTIAL CHARACTER.

Cor. four petalled. *Cal.* four-cleft. *Stigma* ſeſſile, croſs-ſhaped. *Drupe* with an eight furrowed nucleus.

SPECIES.

1. Grias cauliflora. *Anchovy Pear.*
Lin. ſpec. 732. *ſyſt.* 492. *Reich.* 2. 583. *Swartz obſ.* 216. *Brown. jam.* 245. (Calophyllum.) *Sloan. jam.* 2. 122. *t.* 216. & 217. *f.* 1, 2. (Palmis affinis).

DESCRIPTION, *&c.*

[This tree frequently grows to the height of fifty feet. Branches at the top, ſimple, ſhort, or none. Leaves on ſhort petioles, pendulous, two or three feet long, wedge-ſhaped at the baſe, oblong-attenuated, entire, marked with nerves and veins, wrinkled, ſmooth. Flowers from the ſtem, on very ſhort, ſcaly, many flowered peduncles: pedicels ſhort, crowded, one-flowered. Corollas large, whitiſh. Calyx coriaceous, ſmall, ſuperior, the four clefts blunt. Filaments inſerted into a ſquare receptacle, united at the baſe in a five-fold row, bent in, the inner ones ſhorteſt. Drupe ovate, eight-furrowed, crowned with the calyx. Nucleus ſolitary oblong[9].

The uprightneſs of the growth, and the largeneſs of the leaves give this tree a very elegant appearance. The fruit is about the ſize of an alligator's egg, and much like it in ſhape, only a little more acute at one end, and of a brown ruſſet colour. This beautiful tree is frequent in many parts of Jamaica, and grows, generally, in low moiſt bottoms, or ſhallow waters[1].]

The fruit is pickled in the Weſt Indies, and eaten in the ſame manner with the Eaſt Indian Mango, which it exactly reſembles in taſte.

PROPAGATION AND CULTURE.

Put the ſtones into the ground ſoon after the fruit is gathered, and keep the plants conſtantly in the bark-bed in the ſtove.

[In the Weſt Indies the ſeeds grow very readily, wherever they meet with a ſufficient quantity of moiſture, and propagate ſo thick, that the trees are always found formed into thickets or large cluſters[1].]

DESCRIPTION, *&c.*

Petals blue, with livid-yellow claws. Capſule inferior, with the calyx cloſely adhering and ſerving as a bark to it at bottom, flattiſh at top, and ſurrounded with a ring of hard bony tubercles, within which it is crowned with the permanent filaments and ſtyles; it has ten cells, but no valves: to each ſtyle there are two cells, but all of them are placed in a ring regularly round the axis of the fruit, and deeply immerſed in the ſubſtance of the calyx. There is no receptacle, but the ſeeds are fixed to the tip of the cells, one only in each; the form is elliptic, beaked at top, plano-convex, or flatted lens-ſhaped, of a reddiſh cheſtnut colour[1].

Native of the Cape of Good Hope.

GRIMMIA. *(So named in honour of Jo. Fred. Car. Grimm, Archiater at Gotha.)*

DESCRIP-

DESCRIPTIONS, &c.

1. This is a tree with round branches. Leaves like thoſe of Bay, oppoſite, quite entire, with alternate nerves. Raceme ſimple, bent outwards, the length of the leaves, covered with numerous flowers, on pedicels the length of the calyx, all bent upwards in one row. Calyxes green, turbinate. Petals ſcarcely conſpicuous. Stamens very long, purple. Anthers ſulvous.

Native of South America [1].

2. Stem and principal branches erect; ſmaller aſcending; bark ruſt-coloured. Leaves oppoſite, two-faced, acute, ſmooth above. Racemes bearing from five to fifteen flowers, which are pretty large, red and permanent. Calyx red, ſix-toothed, equal, permanent. Petals ſix, ſmall, lanceolate. Filaments equal, inſerted into the calyx near its baſe. Stigma oblong. Capſule covered with the coloured permanent calyx.

It is a beautiful flowering ſhrub, a native of the hills and valleys through the northern provinces of the Carnatic in the Eaſt Indies. The bright-red calyx, retaining its colour till the ſeeds are ripe, gives this ſhrub a very ſhowy appearance [2]. According to Linneus, it is alſo a native of China.

GROMWELL. See *Lithoſpermum*.]

GRONOVIA. *The name was given to this genus by Dr. Houſtoun, in honour of John Fred. Gronovius, M. D. a learned botaniſt at Leyden.*)

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft beyond the middle, bell-ſhaped, coloured, permanent; *diviſions* ſemi-lanceolate, upright.

COR. *Petals* five, extremely minute, roundiſh, from the clefts of the calyx.

STAM. *Filaments* five, capillary, length of the corolla, inſerted into the calyx, alternate with the petals. *Anthers* erect, twin.

PIST. *Germ* inferior. *Style* filiform, longer than the ſtamens. *Stigma* obtuſe, (two-lobed, *H.*)

PER. *Berry* dry, roundiſh, coloured, one-celled. (Fruit five-ribbed, *H.*)

SEED ſingle, roundiſh, large.

ESSENTIAL CHARACTER.

Petals five, together with the ſtamens inſerted into the bell-ſhaped corolla. *Berry* dry, inferior, containing one ſeed.

SPECIES.

1. Gronovia ſcandens. *Climbing Gronovia.*

Lin. ſpec. 292. *Jyſt.* 243. *Reich.* 1. 567. *mant.* 343. *hort. cliff.* 74. *Mart. cent.* 40. *Amm. herb.* 346.

DESCRIPTION, &c.

Gronovia is an annual plant, which ſends forth many trailing branches like thoſe of the Cucumber, cloſely ſet with broad leaves, in ſhape like Vine leaves; thoſe on the ſtalk are covered with ſmall ſpines, [or rather hooked hairs,] which ſting like the Nettle: the branches have many tendrils, by which they faſten themſelves to other plants, and thus will riſe to the height of ſix or eight feet. The flowers are ſmall, axillary and in bunches, of a greeniſh yellow colour, and make no great appearance.

[It has a ſtrong ſmell. The leaves reſemble thoſe of Bryony, are rough and ſtinging. Peduncles many-flowered axillary. It may be doubted whether it is not more truly polypetalous, and allied to the Onagræ [3].]

This plant was diſcovered by Dr. Houſtoun at La Vera Cruz, whence he ſent the ſeeds to Europe about 1731.

PROPAGATION AND CULTURE.

This being a very tender plant, muſt be raiſed on a hot-bed early in the ſpring, and afterwards placed in the bark-ſtove, and treated in the ſame way as the Momordica. Thus it will produce ripe ſeeds; but no uſe of it being known, and having little beauty, it is not cultivated except in botanic gardens.

DESCRIPTIONS, &c.

Theſe are trees, the timber of which is very hard. The leaves are abruptly pinnate. The peduncles axillary and one-flowered. The fruit of *G. officinale* is two-celled, compreſſed and obcordate: that of *G. ſanctum* four or five-celled, with a ſort of wing to each [5].

1. The firſt is the common Lignum Vitæ or Guajacum, and becomes a very large tree, covered with a hard, brittle, browniſh bark, not very thick: the wood is firm, ſolid, and ponderous, appearing very re-

[1] Linn. hort. cliff. [2] Roxburgh [3] Juſſieu. [5] Juſſieu.

sinous, of a blackish yellow colour within, and of a hot aromatic taste; the smaller branches have an ash-coloured bark.

[Leaves pinnate: leaflets two pairs, elliptic, sessile, entire, veined, shining. Peduncles terminating, round, shorter than the petioles, one-flowered. Calycine leaflets ovate, convex, pubescent. Petals ovate, entire. Filaments ten, contiguous at the base. Anthers incumbent, bifid at the base, yellow. Germ obcordate, compressed. Style permanent [a]. Capsule subturbinate (obcordate-angular, *Sw.*), on a very short pedicel, five-cornered, with very narrow winged ribs on the round back of the angles, succulent, smooth, pale ferruginous (or yellow) five-celled, (from two to five-celled, *Sw.*). Partitions quite simple, membranaceous, fixed to the middle of the cover. Seeds large, thicker and blunt above, attenuated below, convex on one side, angular on the other, rufescent. Two or three cells are frequently abortive, but the vestiges of them remain. The rind of the capsule is continuous, and the partitions indivisible; it is one therefore, and not several, as Schreber would have it [c].

Brown describes it as an evergreen of a dark gloomy cast, continuing its verdure in the driest seasons, and at times throwing out a great number of blue flowers, which are succeeded by compressed berries of a roundish form. The tree takes many years to arrive at its full growth. The roots run far into the ground perpendicularly, contrary to the usual growth of timber trees in the West Indies, which generally shoot the largest prongs of their roots in an horizontal direction, and are commonly observed to run very near the surface. The bark is thick and smooth; the wood of a dark olive colour, and cross-grained, the strata running obliquely into one another, in form of an X. As timber it answers where strength and duration are required, and its weight no impediment. It takes a fine polish, and answers well in the turner's lathe; but is now chiefly used for ship-blocks [d].

The gum is obtained by jagging the body of the tree in may. It exsudes copiously from the wounds, though gradually, and when a quantity is found accumulated, hardened by exposure to the air and sun, it is gathered, and packed in small kegs. This gum has been suspected sometimes to have been sophisticated by the negroes, with the gum of the Manchineal-tree, to which it bears some similitude at the first appearance; but it is easily distinguished, by dissolving a little in spirits: the true gum imparts a whitish tinge; but the manchineal gives a greenish cast: and this is still farther distinguishable by pouring a little of the same tincture into water, which takes from the Guajacum almost immediately the complection of milk.

The fruit is purgative, and for medicinal use, far excels the bark. From the flowers also is prepared a laxative syrup, resembling syrup of violets.

The tree rises to the height of forty feet, and measures from fifteen to eighteen inches in diameter. It is certainly one of the most valuable trees in the West Indies; since the body, the bark, gum, fruit, leaves and blossom are all applicable to some useful purpose [e].

The fresh bark opens the body, and is deemed a sweetener of the blood, but the pulp of the berries purges and vomits very violently. The resinous parts of the tree are of a warm active nature, and found, by long experience, to attenuate and dissolve the blood: they are esteemed specifics in old venereal taints, chronical rheumatisms, and other disorders arising from the sizyness of the juices; and generally administered in decoctions (the resin sometimes in boluses) ordered for a continuance: but great care must be taken to moderate or temper the native acrimony of these medicines in the beginning of a course, and to prepare the body for the use of them; the neglect of which has been frequently the cause of very dismal consequences in hot climates, and may probably have the like effects sometimes in colder regions.

There is a tincture made with the gum of this tree, that has been sometimes administered with success, as well as the powder itself, in obstinate intermittent and remittent fevers; in which cases they commonly procure a few stools, as well as promote a general discharge by the skin. The foliage of the tree is of a very detersive nature, and frequently used to scour and whiten the floors in most houses about Kingston: the infusion of them is also used to wash painted linens, and other stained garments; which it is said to do very effectually without changing the lustre of the dyes [f].

The wood and resin only are now used in Europe. Since the use of Mercury it is seldom prescribed in the *lues venerea* [g]; and if it be occasionally employed in *Syphilis*, it is rather with a view to correct other *vitia* in the habit. Dr. Cullen looks upon it as analagous to the balsams and turpentines, and as having a considerable power in stimulating the extreme vessels; and thus accounts for its efficacy in chronic rheumatism; and from its passing off by the pores of the skin, he considers it as a probable remedy in some cutaneous disorders.

In the London Dispensatory there is a tincture of Gum Guaiacum—pulvis Aloeticus cum Guaiaco—and the wood is an ingredient in Decoctum Sarsaparillæ compos.

The Edinburgh college have directed an elixir to be prepared with rectified spirit, or with the vinous spirit of sal-ammoniac; some object to the spirituous tincture, and Dr. Cullen prefers the diffusion of the gum in water [h].

It is a native of the West Indies. In Jamaica it is abundant on the south side, but it is seldom found in any other part of the island.

It was cultivated in 1699, by the Dutchess of Beaufort [i].]

2. The second sort has many leaflets placed along the midrib by pairs; they are rounded and obtuse at their ends, but narrow at their base, of the same consistence with those of the first sort, but of a darker green color. The flowers are produced in loose bunches towards the ends of the branches, are of a fine blue colour, and the petals are fringed on their edges. This is called in some of the islands of the West Indies *Bastard Lignum Vitæ*.

[Cultivated by Mr. Miller in 1759.

3. Branches rigid. Leaves alternate, with eight pairs of leaflets. Common petiole edged, jointed, channelled; leaflets ovate-oblong, opposite, quite entire, mucronate, smooth, stiffish, perennial, very slightly shortened at the inner base. Stipules pressed close to the branches, subulate, very small [k].

Native of the Cape of Good Hope, near Mossel-bay [l]. Mr Miller, in the 7th edition of his Dictionary (1759) says, it has been long an inhabitant of the curious gardens in England and Holland. See *Schotia*, which name was given to this plant by Jacquin, from Richard van der Schot, his companion in his travels.

4. Native of the island of Tongatabu in the South Seas [l].]

PROPAGATION AND CULTURE.

1, 2. These trees can only be propagated by seeds procured fresh from the countries where they grow naturally. As soon as they arrive sow them in pots filled with light earth; plunge them in a good hot-bed, and if the seeds are good, they will appear in six weeks or two months; and in six weeks more they will be strong enough for transplanting; then they should be carefully taken out of the seed-pots, so as to preserve their roots as entire as possible, and each planted in separate small pots filled with light earth, and plunged into a new hot-bed of tanners bark, where they must be shaded from the sun till they have taken fresh root; then they must be treated in the same manner as other tender exotic plants from warm countries, admitting a large share of free air to them when the weather is warm: they will require to be frequently refreshed with water in warm weather, but it must be given them with caution, for too much wet will infallibly destroy them. While the plants are young, they may be kept during the summer season in a hot-bed of tanners bark under

[a] Swartz. [b] Gartner. [c] Browne. [d] Long's Jamaica, 3. 724.

[e] Browne. [f] Woodville. [g] Hort. kew. [h] Linn. syst. [i] Hort. kew. [k] Forster.

a frame; but in the autumn they muſt be removed into the bark-ſtove, and plunged into the hot-bed of tan, where they ſhould conſtantly remain, and muſt be treated in the ſame manner as other tender plants, being careful not to give them too much water in the winter, when it is very prejudical to them, and in ſummer they ſhould have a large ſhare of free air admitted to them every day. With this treatment the plants will thrive very well, but being plants of ſlow growth in their own country, cannot be expected to make great progreſs in Europe.

[In their native country they grow very readily from ſeed; and ſeem fond of a dry ſoil with a hot expoſure.]

3. This will live in a good greenhouſe all the winter, but in ſummer it muſt be placed abroad with other greenhouſe plants. It is of a ſlow growth, and is with difficulty propagated by layers.

DESCRIPTION, *&c.*

This is a tree of a middling ſize, with a ſmooth trunk. Leaves pinnate, without an odd leaflet: common petioles alternate, longiſh, round, ſmooth, aſh-coloured: pairs of leaflets two to four, lanceolate-ovate, obtuſe, entire, nerved, ſmooth: partial petioles ſhort, thick, round. Racemes a foot long, axillary, ſubdivided, looſe, the branches many-flowered, the peduncles very ſhort. Calyx four-cornered, minute; ſegments blunt, ſpreading [a].

All parts of the plant, eſpecially the bark, ſmell ſtrong of muſk, and may be uſed, inſtead of that perfume, for many purpoſes. The wood is full of a bitter reſinous ſubſtance, which renders it unfit for rum-hogſheads; being obſerved to communicate both its ſmell and taſte to all ſpirituous liquors: but it is often cut for ſtaves and heading, when there is a ſcarcity of other lumber. The powder of the bark is ſaid to be a good emetic: and is ſometimes uſed among the negroes for that purpoſe [b].

Native of South America and the Weſt India iſlands, in woods and by rivers ſides: flowering in january and february. The Engliſh call it Muſk-wood and Alligator-wood: the French Bois rouge.

It was cultivated in 1777, by Mr. James Gordon [c].

Swartz. prodr. 59.
Leaves ovate acuminate membranaceous, ſubbriſtidly ſcabrous; flowers with four ſtamens.

DESCRIPTIONS, *&c.*

1. This tree has the habit of Hernandia. The leaves are very large, ovate or obovate, rounded at the end with a point, naked, quite entire, with alternate veins; the petioles are much ſhorter than the leaves, and compreſſed. The peduncle is oppoſite to the petiole, but on the upper branches there are two oppoſite peduncles; they all terminate in a very ſhort dichotomous cyme. The male flowers are ſeſſile, alternate, from the upper ſide only of the cyme: calyxes ſomewhat tomentoſe, ſcarcely apparently two-lobed. Tube of the corolla tomentoſe: lobes of the border oval-oblong, one-third only of the length of the tube. No germ; ſtyle ſhorter by half than the tube: ſtigma cylindric-headed, obtuſe. The female flowers are like the males; but have a germ ſucceeded by a drupe, containing ſix large, woody ſeeds, connected together [d].

According to Gærtner, the flowers are either hermaphrodite or monoecous: the ſtamens from ſix to nine: the pericap a dry, inferior, berried drupe, incloſing a bony ſhell, deeply umbilicated on both ſides, and divided into four or ſix lobes variouſly wrinkled, reſembling that of a walnut; perforated in the circumference for the cells [e].

Browne obſerves that it ſeldom riſes above eight or ten feet in height, or exceeds three or four inches in diameter; that the bark is ſmooth; and the diſpoſition

[a] Swartz. [b] Browne. [c] Hort. kew. [d] Linn. ſpec. [e] Gærtner.

of

of the flowers very remarkable, as well as the texture and form of the leaves. Guettarda of Oſbeck, it. 275. is ſcarcely the ſame ſpecies. G. ſpecioſa of Aublet. guian. 317. is different from this.

Dr. Browne named it after the Rev. Dr. Hales, author of the Vegetable Statics.

It is native of Jamaica, Java, and the Society iſlands in the South Seas.

2. Branches round, oppoſite, ſcarred, ſmooth below, villoſe above. Leaves petioled, from two to three inches long, crowded towards the ends of the branchlets, oppoſite, ovate-oblong, ſometimes narrower towards the baſe, terminated by a ſmall point, quite entire, very rugged on the upper ſurface with minute elevated mucronated dots, underneath netted-veined and wrinkled, with very minute villoſe hairs ſcattered about. Stipules awl-ſhaped, deciduous. Peduncles axillary, oppoſite, compreſſed, villoſe, purple, dilated towards the top, twice or thrice dichotomous. Flowers ſometimes in a head ſubſeſſile. A ſeſſile flower in each diviſion. Bracte awl-ſhaped, deciduous, at the diviſions and below each flower. Calyx pitcher-ſhaped, obſcurely toothed. Tube of the corolla an inch and half long, ſoft and ſomewhat ſilky. Fruit the ſize of a pea, aſh-coloured with villoſe hairs. Found by Weſt, in the iſland of Santa Cruz [c].

Native of the Eaſt Indies [c].

3. Native of Jamaica.

4. Native of St Domingo [b].

According to Juſſieu, we are to refer to this genus *Cadamba jaſminiflora*, of Sonnerat, ind. 2. 228. t. 128. which is the ſame with *Rova-pou* of Rheede malab. 4. t. 47, 48. and Nyctanthes hirſuta of Linneus, which is certainly a Guettarda according to Gærtner, 180.—He doubts whether *G. coccinea* Aublet. Guian. t. 123. be of this genus, or of Hamelia, or between both. See *Iſertia*.]

GUIDONIA. See *Guarea*, *Lætia*. *Samyda*.

GUILANDINA. (*So named in honour of Melchior Guilandinus or Wieland, of Pruſſia, a great traveller; he ſucceeded Anguillara at Padua in* 1561, *and Falloppius in* 1564. *He died in* 1589. *His publications are*, De Stirpibus 1558—de Papyro 1572.)

Claſſ. 10. 1. Decandria Monogynia.

Nat. order of *Lomentaceæ*. *Leguminoſæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, (urceolate or pitcher-ſhaped, *G.*) *Tube* ſhort, turbinate, permanent, with an oblique mouth. *Border* five-parted, nearly equal, ſpreading, deciduous: *diviſions* oblong, broader on the outſide and rounded; the two upper ones a little ſhorter, the loweſt a little longer.

COR. *Petals* five, inſerted into the neck of the calyx; the uppermoſt roundiſh, concave, aſcending, a little ſhorter; the reſt oblong, broader in front, rounded at the tip, reflex-ſpreading, longer than the calyx, and the two loweſt a little longer than the middle ones.

STAM. *Filaments* ſubulate, thicker at the baſe and villoſe, decumbent, inſerted into the neck of the calyx, ſhorter than the corolla, unequal; the lower ones gradually longer. *Anthers* oblong, affixed to the back.

PIST. *Germ* oblong. *Style* filiform, length of the ſtamens. *Stigma* ſimple.

PER. *Legume* rhomboidal, the upper future convex, from ſwelling compreſſed, one-celled, with tranſverſe partitions.

SEEDS bony globular-compreſſed, ſolitary between the partitions.

OBS. *I have only ſeen the male flowers of* G. Bonduc *and* Bonduccella; *it remains therefore to be inquired whether they are dioicous or polygamous.*

ESSENTIAL CHARACTER.

CAL. one-leafed, ſalver-ſhaped. *Petals* inſerted into the neck of the calyx, nearly equal. *Seed-veſſel* a legume.

Lour. cochinch. 265.

Prickly, leaves pinnate, calyx five-leaved, fruit in pairs.]

DESCRIPTIONS, &c.

1. Leaves near a foot and half long, compoſed of ſix or ſeven pairs of pinnæ, each of which has as many pairs of leaflets, which are ovate and entire; the principal midrib of the leaf is armed with ſhort, crooked, ſingle thorns, placed irregularly; the ſtalks are alſo armed with thorns, which are larger. The ſtalks at firſt grow erect, but afterwards twine about the neighbouring trees and ſhrubs. The flowers are in long axillary ſpikes. Petals equal, concave, yellow. Legume broad, thick, three inches long and two broad, cloſely armed with ſlender ſpines, opening with two valves, each including two hard ſeeds about the ſize of children's marbles, of a yellowiſh colour.

[Native of both Indies. Introduced 1690, by Mr. Bentick [a].]

2. The ſecond ſort differs from the firſt in having much ſmaller leaves, ſet cloſer together; and below each pair of leaflets are two ſhort ſtiff crooked ſpines, which are oppoſite; the flowers are of a deeper yellow, and the ſeeds are aſh-coloured.

[Sloane affirms that there is no difference between this and the preceding but the colour of the nut, which in the foregoing is yellowiſh finely variegated with annular or interrupted ſaffron-coloured zones. The in-

[a] Hort. kew.

tegument

tegument is alſo ſtony, but the middle lamina is of a full roſe or fleſh colour [a].

This weakly plant ſpreads a great way about the root, or riſes among the neighbouring buſhes, if it finds a due ſupport. The ſtalk and branches are very full of thorns that arch backwards. The ſeeds are gray, and commonly uſed inſtead of marbles, by boys, in the ſugar colonies [b].

Corolla almoſt regular, with no claws to the petals. Legume ovate-rhomboidal, ſwelling in the middle but flatted at the ſides, with ſpines all over it, ſtiff, but not pungent, ferruginous bay colour on the outſide, pale within; the two valves very ſmooth on the inſide, without any veſtige of a partition. Seeds two or three, ovate-globular, very ſmooth and ſhining, ſeeming as if they had very fine, parallel, annular cleſts, but quite entire; of a livid lead colour, with a brown mark at the navel.

There is a greater affinity between Cæſalpinia and Guilandina than between this and Moringa [c].

In Egypt, the nuts of both theſe ſorts are uſed by the women, ſtrung in necklaces, and hung about their children, by way of amulet, to guard them from ſorcery [d].

They are often caſt aſhore on the north-weſt coaſts of Ireland and Scotland, and are called by the inhabitants of the latter Molucca Beans [e].

This tree makes a good fence.—It is native of both Indies, China, and New Zealand; and was cultivated by Mr. George Willmer at Stratford Bow, before 1640. He raiſed it from ſeed brought from the Weſt Indies to the height of three or four feet, but it periſhed the next winter, for want of ſuch due keeping, as was fit for ſuch tender plants [f].

Johnſon in Gerarde calls the ſeeds, *Beazor Nuts*, and ſays that they were offered to ſale for Eaſt-Indian Bezoar.

3. Branches thorny. Leaves thick, ſolid, ſmooth, oppoſite. Flowers yellow [g]. Legumes ſmooth.

Native of Amboina [h], and Malabar, in ſwamps by the ſides of rivers.

4. This tree has a thick root of a ſofter ſubſtance than uſual. Trunk of a middling ſize, from twelve to twenty feet in height, ſmooth, with an aſh-coloured bark. Branches rather erect. Leaves bipinnate: common petioles two or three feet long, round, ſmooth, ſtiff; the partial ones in five or ſix pairs, horizontal, compreſſed: leaflets in three pairs, ternate, oblong, entire, ſmooth, veined. Flowers in racemes, which are long, axillary, round, pubeſcent, ſubdivided, many-flowered; the ſubdiviſions branched, directed one way, bent down; under theſe are minute, deciduous ſcales. Calyx five-leaved; three upper, two lower; all equal, bent back, lanceolate, obtuſe, coloured, whitiſh or pale red, pubeſcent. Corolla: four of the petals anterior, equal, bent down, pale; one poſterior, erect, a little larger, whitiſh: the baſe nectareous. Filaments: five longer, being the length of the larger petal, and upright; anthers cordate, incumbent, fertile, yellow: the five ſhorter ones barren. Germ lengthened out, three-cornered, acuminate, pubeſcent: ſtyle ſubulate, ſhort: ſtigma acute. Legume two feet long, ſtreaked, three-valved, one-celled. Seeds fifteen or ſixteen, diſtinct, placed longitudinally, oblong, three-cornered, with three membranaceous wings [i].

Gærtner calls the ſeed-veſſel a Capſule: and deſcribes it as fungous-coriaceous, ſubulate, furrowed, three-cornered; the valves thick, angular inwards, and hollowed in the internal angle with large round excavations for the reception of the ſeeds; which are ſometimes eighteen in number, in one row, of a dirty brown colour; they are fixed, not to the ſide, but to the middle of the valves.

This ſpecies therefore ſeems different from the Guilandinas, in the calyx, ſtamens, fruit and habit [k].] See MORINGA.

The root when young is ſcraped, and uſed by the inhabitants as Horſe-radiſh is in Europe, having much the ſame ſharp taſte; as have alſo the ſeeds.

[a] Gærtner. [b] Browne. [c] Gærtner. [d] Sloane and Long. [e] Sloane. [f] Park. theat. [g] Hort. malab. [h] Linn. ſpec. [i] Swartz. [k] Swartz and Linn. ſyſt.

[Native of the Eaſt Indies; cultivated in Jamaica and Egypt.—Mr. Miller cultivated it here in 1759 [a].

Moringa aptera, which is Balanus myrepſica and Been album offic. has ſeeds double the ſize of this, turbinate, ſnow white, without any veſtige of wings [b].]

5. Stem erect, thirty feet high or more, dividing into many branches, covered with a very ſmooth blueiſh aſh-coloured bark. Leaflets oval, very ſmooth and entire, alternate. There are male and female flowers on different plants.—Native of Canada, whence it was firſt brought to Paris.

[Cultivated in 1748, by Archibald Duke of Argyle [c].

6. Stem ſhrubby, large, ſuberect, with many climbing branches, on which are many recurved, ſcattered prickles. Leaves ſimply pinnate, without an odd leaflet: leaflets ovate, obtuſe, quite entire, ſmooth with a ſolitary prickle at the baſe. Flowers yellow, in compound, looſe, terminating racemes. Calycine leaflets obtuſe, woolly, bell-ſhaped-ſpreading. Petals ſcarcely longer than the calyx. Nectary four ovate glands. Filaments hairy, equal: anthers ſagittate. Germs two longiſh; ſtyles two thick, longer than the ſtamens: ſtigmas blunt. Legumes two, ſubovate, compreſſed, echinate. Seeds two or three, roundiſh, ſhining, aſh-coloured, very hard, containing a roundiſh, oily kernel like an almond.

Native of Cochinchina, and more like the Bonduc than Bonducella [d].]

PROPAGATION AND CULTURE.

The four firſt ſorts being natives of warm countries, will not live through the winter in England, unleſs they are placed in a warm ſtove, and the pots plunged into the tan-bed. They are propagated by ſeeds, but thoſe of the two firſt ſorts are ſo hard, that unleſs they are ſoaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to ſoften their covers, they will remain years in the ground without vegetating: when the plants come up, they will be fit to tranſplant in a ſhort time; then they ſhould be each tranſplanted into a ſmall pot, filled with light freſh earth, and plunged into a moderate hot-bed of tanners bark, ſhading them till they have taken freſh root; then they muſt be treated in the ſame manner as other tender exotic plants, giving them a large ſhare of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they muſt be removed into the bark-ſtove and plunged into the hot-bed, where they will make great progreſs, provided they have not too much water, eſpecially during the winter ſeaſon, for theſe plants are very impatient of moiſture in cold weather.

The fourth ſort requires the ſame treatment as thoſe before-mentioned, but the ſeeds will grow without being ſteeped in water; and the plants are with difficulty ſhifted from one pot to another, for their roots are large, fleſhy, and have but few fibres; ſo that unleſs great care is taken, all the earth will fall away from them, which often cauſes their ſtalks to decay almoſt to the root, and ſometimes occaſions the loſs of the plants. This plant muſt be ſparingly watered at all times, but particularly in cold weather, when moiſture will cauſe it to rot in a ſhort time.

5. This ſort will live abroad, and is never hurt by froſt. It is propagated by cutting off ſome of the horizontal roots, or by ſuckers. It requires a light ſoil, not too moiſt.

DESCRIPTION, &c.

[This is a milky plant. Leaves alternate, prickly; floral leaves decurrent. Flowers terminating. Habit that of a thistle [1].]

Root perennial, running deep into the ground. Stalks seldom more than a foot and half high. The under leaves are long, narrow, and serrate, the teeth ending in a spine; the other leaves are broader, irregularly flashed to the midrib, and armed at the points with sharp prickles. The stalks divide at top into several branches, which are armed with leaves of the same form, but narrower; each is terminated by a conical head of flowers, resembling those of Dipsacus, surrounded at the base by a circle of long narrow prickly leaves. Few of the seeds ripen perfectly; and if rain happens when the plants are in flower, the germ perishes, which is the case with several other plants whose flowers are collected into heads.

Native of the Levant.

It flowers in june, and the seeds ripen in august. The seeds were given to Mr. Miller by Dr. Alexander Russel, of Lime-street, who procured them from Aleppo. [Cultivated by Mr. Miller in the year 1739.

PROPAGATION AND CULTURE.

This plant is propagated by seed, which should be sown the beginning of March, in a warm dry border of fresh, but lean earth, in the place where the plants are designed to remain. When the plants come up, they must be carefully cleared from weeds; as they grow large, they should be thinned, leaving the plants which are designed to remain, about two feet asunder, that they may have room to spread. After this there is no other culture required, but to keep them clear from weeds; and if the frost should prove severe in winter the plants should be covered with straw or peas-haulm to protect them; but this covering must be taken off in mild weather; in two years they will produce their flowers, when they will make a fine appearance amongst other hardy plants in the pleasure garden. They flower in may, and the plants lose their stalks and leaves in autumn, but their roots will abide many years.

DESCRIPTION, &c.

A tree, with thickish branches, and from twenty to thirty feet high. Leaves alternate, subsessile, some-

[1] Linn. mant. [2] Hort. cliff.

what

what crowded, in the upper part broad-lanceolate, narrower at the base, from a span to a foot in length, ribbed, subserrate, smooth on both sides. Peduncles from one to three, terminating, bearing one flower, and having one joint. Flower very specious, larger than the white Water-lily, with a large, naked, bald disk or receptacle between the corolla and the style; petals white, with red tips, the consistence of the White Lily. Filaments united at bottom into a membrane, and being inserted into the base of the corolla, are of the nature of those in the class Icosandria; style minute, yellow [c].

The seed-vessel is a juiceless berry, of a turbinate-globular-form, with muscular-like swellings, truncate at top, and rightly concave, produced at bottom into a conical furrowed peduncle; the skin is coriaceous, whitish ash-coloured, veined, yellow within, and very smooth; the cells are from four to seven; and the partitions are thin, like paper, and flexuose. The seeds are from three to five in each cell, ovate, variously angular from the pressure of those next them, of a yellowish cinnamon colour, fixed to the internal angle of the cells from the top to the middle by permanent, twisted umbilical chords, so that the upper ones are pendulous, but the lower obliquely or horizontally decumbent [d]. The flowers smell like the Lily; but the wood is extremely fetid, even after it is dry; the inhabitants use it for hoops [e]. It is a native of Surinam and the island of Cayenne.

Pirigara Nexapetala, *Aublet guian.* 490. *t.* 193. is a distinct species from this [f].]

GUTTA. See *Cambogia.*

[GYMNANDRA. See *Barisia.*

GYMNANTHES. (Γυμνανθης, *having naked flowers.*)
Lin. gen. Schreb. n. 1465. *Swartz prodr.* 95.
Class. 21. 8. Monoecia Monadelphia.

GENERIC CHARACTER.

* *Male Flowers.*

CAL. *Ament* compound, with pedicels tripartite or trichotomous, anther-bearing.
COR. none.
STAM. *Filaments* naked, or pedicels tripartite or trichotomous, scattered, placed on every side of the ament, very short, deciduous. *Anthers* oblong, minute, three-celled.

* *Female flowers* on the same or a different shrub, solitary or amentaceous.

CAL. *Perianth* none, but one or two scales at the base of the germ.
COR. none.
PIST. *Germ* roundish, superior. *Style* scarcely any, or very short, three-cornered. *Stigmas* three, linear, acute, channelled, reflex.
PER. *Capsule* tricoccous, three-celled, three-valved.
SEEDS solitary, roundish.

ESSENTIAL CHARACTER.

MALE. *Ament* naked. *Perianth* and *Corolla* none. *Stam.* pedicels three-parted or three-forked, anther-bearing.
FEM. *Ament* or germ pedicelled. *Cor.* none. *Style* trifid. *Capf.* tricoccous, three-celled.

SPECIES.

1. Gymnanthes elliptica.
Swartz prodr. 96.
Dioicous: flamens three-parted, females amentaceous.
2. Gymnanthes lucida.
Swartz prodr. 96.
Monoicous: flamens trichotomous; females solitary, pedicelled.

These shrubs were found by Swartz in the West-Indies; the first in Jamaica, the second in Hispaniola.

GYNOPOGON. (*From* γυνη *a woman, and* πωγων *a beard. The stigma of the flower being bearded.*)
Lin. gen. Schreb. n. 414. *Forst. gen.* 18. *Juss.* 148.
Class. 5. 1. Pentandria Monogynia.
Nat. order of *Apocineæ.* Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, very small, half-five-cleft, permanent; *segments* linear, acute, erect.
COR. monopetalous, contorted: *tube* cylindrical, ventricose below the tip, contracted at the throat: *border* flat, five-parted, *segments* ovate.
STAM. *Filaments* five, very short, inserted into the tube above the middle. *Anthers* erect, linear, within the tube.
PIST. *Germ* ovate. *Style* filiform, shorter by half than the tube. *Stigma* globular, two-lobed, villose at the tip.
PER. *Berry* pedicelled, subglobular, coriaceous, filled with the seed.
SEED single, cartilaginous, subbilocular; with one or two kernels.
OBS. *The fruit is generally abortive, the seed not having kernels: the germs when cut through have two cells, and two seeds in each cell.*

ESSENTIAL CHARACTER.

Cal. half-five-cleft, inferior, permanent. *Cor.* five-parted, tube ventricose below the tip, throat contracted. *Stigma* globular, two-lobed. *Berry* pedicelled, subglobular. *Seed* cartilaginous, subbilocular.

SPECIES.

1. Gynopogon stellatum.
Forst. gen. 18. *n.* 1. *fl. austr. n.* 117.
Leaves in whorls, three together, lanceolate.
2. Gynopogon Alyxia.
Forst. fl. austr. n. 118.
Leaves in whorls, five together, obovate.
3. Gynopogon scandens.
Forst. fl. austr. n. 119.
Leaves opposite, ovate, ribbed.

Natives of the Islands in the South seas. The first of the Society and Friendly islands; the second of Norfolk island; and the third of the Society islands [g]. At Otaheite in may 1774.

GYPSOPHILA. (*From* γυψος *&* φιλω, *amica gypsi, fond of a gypseous or calcareous soil.*)
Lin. gen. n. 563. *Reich.* 612. *Schreb.* 768. *Juss.* 301.
Class. 10. 2. Decandria Digynia.
Nat. order of *Caryophyllei.*

GENERIC CHARACTER.

CAL. *Perianth* bell-shaped, angular, five-parted; *leaflets* ovate, permanent.
COR. *Petals* five, ovate, obtuse, spreading, subsessile.
STAM. *Filaments* subulate, spreading. *Anthers* roundish.
PIST. *Germ* almost globular. *Styles* filiform, gaping. *Stigmas* simple.
PER. *Capsule* globular, one-celled, five-valved.
SEEDS very many, roundish.
OBS. G. paniculata *is dioecous.*

ESSENTIAL CHARACTER.

Cal. one-leafed, bell-shaped, angular. *Petals* five, ovate, sessile. *Capf.* globular, one-celled.

Leaves linear, calyxes angular, with four ſcales, corollas emarginate.

DESCRIPTIONS, &c.

1. The whole plant is ſmooth. Root perennial, woody, very long, as thick as the little finger. Stems many in a cloſe tuft, ſpread every way, half a foot in length, perennial: branches herbaceous, erect from three to ſix inches high, ſimple, reddiſh at the joints, forming an imperfectly trichotomous panicle at top. Leaves lanceolate-linear, acute, glaucous, thick, ſeſſile, oppoſite, ſeldom ſo long as an inch. Flowers remote, few, on bifid or trifid peduncles. Calycine leaflets lanceolate, acuminate, concave, with a dark green or purple line along the middle, and white membranaceous edges. Corolla white or red, ſpreading very much; petals flat, a little attenuated towards the baſe, more or leſs emarginate, twice as long as the calyx. Filaments longer than the calyx, and not much ſhorter than the corolla. Anthers twin, at firſt whitiſh, but turning of a pale red. Styles ſcarcely longer than the petals. Capſules blunt [a].

Native of Siberia, Auſtria, Switzerland and Provence: flowering in ſeptember.—Introduced in 1774, by Monſ. Richard [b].

2. Root perennial. Stems ſeveral, ſmooth, round, about a foot in length, reddiſh at the joints. Panicle brachiate, trichotomous, the middle peduncle more ſimple than the others. Corolla white (Miller and Plukenet ſay purpliſh); petals obtuſe, ſpreading, channelled at the tip; ſtamens only half the length of the corolla; ſtyles a little longer than it. It much reſembles the foregoing; but differs in the root hardly creeping—the joints of the ſtalk being leſs purple—the leaflets of the calyx not keeled—the corollas ſmaller and white, not reddiſh—the anthers yellow—the ſtyles diverging, longer than the petal—and the leaves leſs fleſhy [c].

It flowers from june to ſeptember; and was cultivated in 1759, by Mr. Miller [d].

Its native country is not certainly known: but it is ſuppoſed to come from ſome of the mountainous parts of Europe.

3. Leaves ſcabrous at the edge. Stamens at the bottom of the flower. Petals rolled back, ſmaller than in the other ſpecies. Styles bent in [e].

Root perennial, thick, fleſhy. Stems ſeveral, round, jointed, proſtrate, a foot and half long, the thickneſs of a quill, below villoſe and rugged, four-cornered and ſimple, above ſmooth. From the middle upwards ſpring aſcending branches, ſubdivided alternately, a foot long, ſhining, ſmooth, leafy, pale, ending as does the ſtem itſelf in a flowering panicle. Leaves narrow-lanceolate acute, oppoſite, ſeſſile, quite entire, thick, ſomewhat glaucous, the loweſt three inches long, the upper ones gradually ſmaller. Peduncles branched. Flowers very numerous, and without ſcent. Calyx ſmooth, obtuſely five-grooved, leaflets blunt, green, with white edges. Petals white, oblong, blunt, quite entire, twice as long as the calyx. Native of Hungary, flowering in july and auguſt [f]. Alſo of Siberia and Tartary, according to Mr. Miller, who cultivated it in 1759 [g], and to whom the ſeeds were ſent from Peterſburgh.

4. Root annual, ſlender. Plant from a long ſpan to a foot in height, very ſmooth, glaucous. Stem erect, ſlender, branched almoſt from the bottom. Branches oppoſite, inſerted croſſwiſe, gibbous at the baſe, elongated, aſcending. Leaves ſomewhat fleſhy, acute, an inch and half long, ſpreading very much. Panicle terminating, diffuſed and almoſt faſtigiate, dichotomous: peduncles alternate, ſlender, gibbous at the baſe; pedicels rigid, long, divaricate, the outmoſt three-flowered, the axillary one-flowered. Stipules of the peduncles and pedicels lanceolate, membranaceous, ſmall, preſſed cloſe. Flowers the ſize of thoſe in the firſt and ſecond ſpecies. Calyx ſubglobular, not angular; the parts concave, blunt, joined by a membrane at the baſe. Corolla ſcarlet red, twice as long as the calyx, without ſcent, petals oblong, emarginate. Stamens equal in length to the corolla, diſtant: filaments white: anthers gray. Styles two, very ſeldom three, ſhorter than the ſtamens, bent back at top, permanent: ſtigma blunt. Capſule four-valved, with prominent ſutures. Seeds ſomewhat kidney-ſhaped, ſtriated, black [h].

Native of the Levant.—Introduced in 1773, by Mr. William Forſyth.—It flowers in june and july [i].

5. Root perennial, whitiſh, branched, and woody. Stems very many, round, ſmooth, much jointed, leafy, herbaceous, purple at the baſe and procumbent, then aſcending.

[a] Jacquin & Gerard. [b] Hort. kew.
[c] Linn. ſpec. [d] Hort. kew. [e] Linn. ſpec.
[f] Jacquin. [g] Hort. kew.
[h] *Murray in comm. gott.* [i] Hort. kew.

afcending. Branches numerous, ending in ſlender erect branched peduncles. Leaves quite entire, glaucous, pulpy, ſharpiſh, ſeſſile and oppoſite. Petals twice or three times as long as the calyx, pale fleſh-colour, obovate, emarginate or blunt. Filaments pale, almoſt the length of the corolla, anthers red. Styles ſlender, awl-ſhaped [s].

6. This differs from the next ſpecies in being twice or four times the ſize in all the parts. The ſtructure is the ſame, but yet it is a different ſpecies. The ſtalk is upright, and a foot and half in height; the leaves are the length and breadth of a finger. It is perennial.—Native of Siberia [t]. Introduced in 1777, by Abbé Nolin.—It flowers in july [u].

7. Stem ſhrubby at bottom, with leafy rudiments from the axils of the leaves, which are longer than the internodes, and acute at the end. Flowers in corymbs, white, with ovate petals. The ancients uſed this plant inſtead of ſoap; and it ſtill anſwers this purpoſe in ſome parts of Spain, where it grows naturally [x].

Introduced in 1774, by Monſ. Richard.—It flowers in july and auguſt [y].

8. *Root* perennial, very long, the thickneſs of a finger, white, woody. *Stalks* ſeveral, ſtiff, jointed, ſmooth, more than a foot long, branched, ending in a denſe, faſtigiate cyme of flowers. *Leaves* glaucous-green, oppoſite, ſeſſile, embracing the joints of the ſtalk with their broad braces, quite entire; the uppermoſt very ſmall; next the root very many, two inches long, and a line and half broad: between the peduncles ſmall, white ſtipules. Petals pale roſe-colour. Capſule four-celled. Seeds black, lens-ſhaped [z].

The ſtalks in this ſpecies are procumbent before the flowers expand, which is not the caſe in *G. proſtrata*; hence the flowers in this are all directed one way. Linnæus obſerves that the flowers in Sweden are always white, and that in its wild ſtate they are faſtigiate. The root, as in the foregoing ſpecies, has a ſaponaceous quality, and boiled with linnen or woollen may be uſed inſtead of ſoap [a].—Hence the name of *Saponaria*.—It is bitter, and has a ſolvent, aperient quality [b].

Native of Sweden, Germany, Switzerland? France, Siberia.—It flowers from june to auguſt.—Cultivated in 1759, by Mr. Miller [c].

9. Root perennial, ſtrong, fleſhy, ſtriking deep into the ground, ſending up ſtalks two and three feet in height, as thick as the little finger at bottom, ſwelling at the joints, branching at ſhort intervals from top to bottom; branches ſingle, alternate, divided and ſubdivided; the firſt diviſions of the flowering panicle dichotomous, the laſt trichotomous; pedicels ſlender and ſcattered on every ſide: flowers numerous, before they expand purple, but becoming paler, and at length white. Lower leaves ſubhirſute, glaucous, reſembling thoſe of Sopewort, but thicker; upper ones narrower and ſmooth, like thoſe of Cucubalus Behen. Thoſe at the baſe of the peduncles and pedicels very narrow, and the uppermoſt capillaceous. Capſule obtuſely four-cornered, four-valved [d].

Native of Spain and the Levant. Flowering in july and auguſt.—Cultivated in the Eltham garden in 1732.

β. Native of Spain.

10. Root annual, ſlender, ſmall. Stalk diffuſed, a ſpan in length, weak, and therefore ſeldom upright. Leaves very narrow, connate, often turned to one ſide, an inch and half long, from half a line to a line in breadth, bright green. The flowers come out at the diviſions of the ſtalk ſingly, on ſetaceous peduncles, one at the end. Petals ſerrate or emarginate, pale roſe-colour, marked with darker lines, having a long greeniſh claw. Anthers whitiſh. Stigmas whitiſh, blunt [e].—It reſembles *G. ſaxifraga*, but has not the calycine ſcales [f].

Native of Lapland, Sweden, Germany, Switzerland, France, Siberia.—It flowers with us from june to october.

In its wild ſtate it is rather an autumnal plant, coſſimon in the ſtubble of cultivated fields; alſo by road ſides, on walls, and in marſhy boggy places. I found it flowering in october 1778, in the ſtubbles about Vandouvre in the territory of Geneva.

It was introduced in 1773, by the Rev. John Lightfoot, M. A. and is biennial [g].

11. From a very fibrous root ſpring numerous little ſtems, not more than a ſpan high, jointed, branched. Flowers pale red [h]. Native of the South of France and Siberia.

12. Root perennial, woody, branched. Stalks in tufts, procumbent, a long ſpan or about nine inches in length, very much branched, bent, and changing their direction at each joint. Leaves on the younger ſtems crowded, very narrow. Flowers on long peduncles, on the extreme ſubdiviſions, which are almoſt naked. At the baſe of the calyx are two pairs of broad ſcales, ending in long awns. Calyx itſelf ſhort, five cornered, with white wings. Petals emarginate, white, with roſe-coloured lines [i]. According to Linnæus, the ſtalk is only three or four inches high, upright, filiform, dichotomous; leaves ſharp; petals pale fleſh-colour, with three obſcure, purple ſtreaks at the baſe. Scopoli obſerves, that the flowers have only eight ſtamens, or even fewer; that the capſule is four-valved, and the ſeeds compreſſed and black.—Native of France, Switzerland, Auſtria, Carniola. It flowers in july and auguſt.—Introduced in 1774, by Monſ. Richard [k].]

PROPAGATION AND CULTURE.

Theſe plants having no great beauty, are rarely cultivated but in botanic gardens. They are propagated by ſeeds, ſown in a bed of light earth, and when the plants are fit to remove, they may be tranſplanted into the places where they are deſigned to remain, and will require no other culture but to keep them clean from weeds; for the roots of moſt ſorts will continue ſeveral years, and annually produce flowers and ſeeds.

Leaves linear keeled.

8. Hæmanthus multiflorus. *Many-flowered Hæmanthus* or *Blood-flower.*
Lin. ſpec. Willd. 2. 24. *Mart. monogr. Vallet. hort. t.* 33. *De Bry floril. t.* 44. *Swert. floril. t.* 62. *f.* 3. *Moriſ. hiſt. ſ.* 12. *t.* 12. *f.* 11. *Rudb. elyſ.* 2. *t.* 210. *f.* 3. *Seba. theſ.* 1. *t.* 12. *f.* 1, 2, 3.
Leaves three together, ovate-lanceolate, acuminate, keeled, waved, upright; umbel cloſe, globular; petals ſpreading.

DESCRIPTIONS, *&c.*

1. Root large, bulbous, from which in autumn come out two broad flat leaves, of a fleſhy conſiſtence, ſhaped like a tongue, which turn backward on each ſide, and ſpreading flat on the ground, have a ſingular appearance all the winter; but in the ſpring they decay. The flowers are produced in autumn, juſt before the new leaves come out; they are of a bright red, in a large cluſter, two or three inches from the bulb.

[It is a native of the Cape of Good Hope; and was cultivated by Mr. Miller in 1731 [a].]

2. Roots compoſed of many thick fleſhy tubers, forming a head, out of which ariſes a fleſhy ſpotted ſtalk, ſpreading at top into ſeveral ſpear-ſhaped leaves, which are waved on their edges. Stalks a foot high; leaves ſix or eight inches long, and two broad in the middle. From the ſide of the ſtalk near the ground breaks out a ſtrong fleſhy ſcape, ſix or eight inches long with a large cluſter of yelloviſh red flowers at top. [Berry obovate, fleſhy, ſcarlet: fleſh ſoft, thin: partitions membranaceous: cells generally unequal, one larger and fertile, the others ſmaller and barren, or even quite obliterated. Seed ovate, narrowing downwards, obſcurely three-cornered, pale, upright when ripe, but before that time horizontal [b].

This is a native of Africa; it was received from Holland, and cultivated in 1722 at Eltham, by James Sherard, M. D. [c]

3. Found at the Cape of Good Hope by Thunberg and Maſſon.—It flowers in auguſt; and was introduced in 1774 [d].

4. Bull large. Leaves like thoſe of the firſt ſpecies, but ciliate, as in *Amaryllis guttata*, which however has much narrower leaves, more like thoſe of Narciſſus. The cilias in this are brown, whereas in the Amaryllis they are pale [e].—It is a native of the Cape of Good Hope; and was introduced in 1774, by Mr. Francis Maſſon [f].

5. This alſo is a native of the Cape, where it was found both by Thunberg and Maſſon. The flowers are fleſh-coloured. It was introduced in 1774 [a].

6. A native of the Cape, and flowers with us in ſeptember. It was introduced in 1774, by Maſſon [a].

See Amaryllis ſpiralis, which is the ſame plant.]

7. This has a large bulbous root ſending out three or four leaves, a foot long or more, not flat but hollowed like the keel of a boat, and more erect than thoſe of the firſt ſort, but not quite ſo broad: the flowers are of a paler red.

Native of the Cape. Mr. Miller received the roots from Dr. Adrian van Royan, profeſſor of botany at Leyden.

[8. Bulb from one to three inches in diameter, the upper part tinged of a red colour, and ſpeckled like the ſtalk. Scape from eight to eighteen inches in height, ſpeckled with dark red almoſt to the top, round or flatted, ſometimes fluted on one ſide. Umbel of flowers from three to nine inches in diameter, containing from twelve to forty, fifty or ſixty flowers. Involucre or ſpathe not always of ſix leaves, but varying from three to ſeven; the leaves are oblong, bent back to the ſtalk, and permanent. Peduncles one inch long, with a white bracte like a thread at the baſe of each. Corolla of a clear ſhining blood-red colour, divided to the bottom into ſix narrow parts, which are pointed and ſpread out wide. Filaments upright, curved a little upwards, divaricating. Anthers of a fine bright gold colour, with a ſmall black ſpeck. Style the length of the ſtamens; both longer than the corolla. Seed-veſſel a roundiſh berry. The leaves are on a ſeparate ſtalk by the ſide of the ſcape, of a fine light-green colour, from ſix to twelve inches in length or more, in breadth from two to four inches. The regular number ſeems to be three, but ſome plants have only two, and others four, five or ſix. The leaf-ſtalk is ſpeckled like the ſcape, and emerges from a cup or large ſcale of a duſky red colour on the outſide, about the time when the ſpathes or involucres open to ſhow the flower. The leaves ſtand in ſome plants nearly as high as the bottom of the flowers; in others, as high as the top or even higher; and do not diſplay themſelves entirely till after the flowers are paſſed.

Native of Sierra Leone in Africa. It was ſent to the Paris garden by the younger Robin from Guinea in 1603. He found it abundantly in the iſlands on the coaſt, called Bugigos, in woods near the ſhore; ſince that it has been loſt in Europe till about the year 1794. Vallet's figure is erroneous, yet it is implicity copied by De Bry, Swertius, Moriſon and Rudbeck. Seba's is different, and much better.]

PROPAGATION AND CULTURE.

The firſt and ſeventh ſorts are with difficulty propagated in Europe, for their roots put out offsets but ſparingly, the gardens in Holland therefore are ſupplied with them from the Cape of Good Hope, where they naturally grow, and produce ſeeds; the plants are too tender to thrive in this country in winter in the open air, therefore the roots muſt be planted in pots filled with light loamy earth, and, in the winter, placed in a dry glaſs-caſe, where, during that ſeaſon, the leaves will be in full vigour, and make a pretty appearance, when intermixed with other plants in the ſtove: though they ſeldom flower here, yet are they worthy of a place in every garden where there is conveniency of keeping them. The roots may be taken up when their leaves are decayed, and kept out of the ground till auguſt, when they ſhould be new potted, and may remain abroad till the end of ſeptember, at which time they may be removed into the glaſs-caſe, and during the time they are growing, will require to have frequent waterings, but it muſt not be given to them in large quantities.

If a border is made either againſt the front of the green-houſe or ſtoves, which may be contrived ſo as to be covered with glaſſes in winter, in which theſe roots, with the African Gladiolus's, Ixia's, Perſian Cyclamens, &c. are planted in the full ground, they

[a] Hort. kew. [b] Gærtner. [c] Dellenius. [d] Hort. kew. [e] Linn. ſpec. [f] Hort. kew.

[a] Linn. ſuppl. and Hort. kew. [b] Hort. kew.

will flower more conſtantly, and the foot-ſtalks will riſe much higher than thoſe kept in pots.

The ſecond ſort is alſo a native of the Cape of Good Hope, from whence it was firſt brought to Holland, where it has been propagated and diſperſed over Europe; this may be propagated by parting the roots; the beſt time for this is in the ſpring, before the plants put out new ſtalks, which is alſo a right time to ſhift and new-pot them; but as the roots do not multiply very faſt in offſets, the beſt way is to propagate them from ſeeds, which they ripen plentifully in England; theſe ſhould be ſown ſoon after they are ripe, in pots filled with light earth, and kept in the ſtove all the winter; if theſe pots are plunged into the tan-bed in the bark-ſtove, in the vacancies between the plants, the earth will be kept warm, and will not dry ſo faſt, as when they are placed in a dry ſtove, ſo the ſeeds will be ſooner prepared to vegetate; in the ſpring the pots may be taken out of the ſtove, and plunged into a hot-bed, which will bring up the plants; theſe muſt have air admitted to them every day in mild weather, to prevent their drawing up weak; and when they are fit to remove, they may be each planted in a ſeparate ſmall pot filled with light earth, and plunged into the hot-bed again, to promote their taking new root; then they muſt be gradually hardened, and afterwards may be removed into the dry ſtove, where they ſhould conſtantly remain, otherwiſe the plants will not thrive and flower in this country. In the winter ſeaſon they muſt not have too much wet, for as their roots are fleſhy and ſucculent, they are apt to rot with moiſture. In the ſummer they muſt have a large ſhare of air in warm weather, and require to be frequently watered, eſpecially during the time of their flowering.

HÆMATOXYLUM. (*From* αἷμα, *blood*, *and* ξυλον, *wood.*)

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, coloured: *tube* very ſhort, pitcher ſhaped, fleſhy, permanent: *border* five-parted, ſpreading, deciduous: *parts* oblong, blunt; the four upper ones equal, the loweſt a little longer than the reſt.

Cor. *Petals* five, lanceolate, broadeſt at top, blunt, veined, ſpreading, nearly equal, inſerted into the calyx, and larger than its diviſions.

Stam. *Filaments* ten, ſubulate, hairy at bottom on the inſide, upright, unequal ſcarcely longer than the corolla, inſerted into the calyx. *Anthers* oval, ſmall.

Pist. *Germ* oblong-ſabre-ſhaped, compreſſed. *Style* capillary, bent at the tip, longer than the ſtamens. *Stigma* funnel-ſhaped.

Per. *Legume* lanceolate, flat, blunt, one-celled, edged on each ſide with a thickiſh future that does not open, opening by the burſting of the valves in the middle longitudinally, and dividing into two unequal boat-ſhaped parts.

Seeds few, oblong, compreſſed, furrowed, fixed to one of the futures.

ESSENTIAL CHARACTER.

Cal. five-parted. *Pet.* five. *Legume* lanceolate, valves boat-ſhaped.

SPECIES.

1. Hæmatoxylum campechianum. *Logwood. Bloodwood. Campeche wood.*

Lin. ſpec. 549. *Reich.* 2. 267. *hort. cliff.* 160. *mat. med.* 114. *Plenk, ic. t.* 329. *Woodv. med. bot.* 48. *t.* 17. *Jacqu. obſ.* 1. 20. *Swartz obſ.* 170. *Brown. jam.* 221. *Sloan. jam.* 2. 183. *Cateſby car.* 3. *t.* 66. *Raii hiſt.* 3. *dendr.* 132. (Lignum campechianum).

DESCRIPTION, *&c.*

This tree grows naturally in the bay of Campeche, at Honduras, and other parts of the Spaniſh Weſt Indies, where it riſes from ſixteen to twenty-four feet high. The ſtem is generally crooked, and ſeldom thicker than a man's thigh. [The inner bark is red, and the wood is hard. Branches ſubdivided, flexuoſe, prickly, round, aſh-coloured. Leaves pinnate: petioles alternate, patulous, round, ſmooth; leaflets four pairs, on very ſhort petiolules, generally obcordate, entire, ſmall, veined, very ſmooth and ſhining, ſpreading in the day time, but at night upright, converging. Prickles ſtrong, middling in ſize, above the petioles. Racemes axillary, ſimple, upright, the length of the leaves, ſolitary, many-flowered. Flowers peduncled, numerous, ſmall, pale yellow; on ſhort, ſcattered, ſimple, coloured peduncles. Calyx bell-ſhaped at the baſe and very ſmall, the parts lanceolate, convex, reflex, purple; the bottom nectareous. Petals ovate, blunt, equal, with ſhort claws. Anthers incumbent, revolute. Germ lanceolate, on a ſhort pedicel. Stigma dilated, perforated.—It flowers in march and april, and ripens its ſeeds in july [a].

It was cultivated here by Mr. Miller in 1739 [b].

Logwood was firſt propagated in Jamaica in 1715, from ſeeds brought from the bay of Campeche. In the neighbourhood of Savannah la Mar ſuch quantities of it now grow wild as to incommode the landholders extremely; occupying that diſtrict, as the Opoponax and Caſhew have the ſouthern parts of Middleſex county. It was firſt introduced to prevent the neceſſity of forming ſettlements upon the Spaniſh Main, but the event did not fully anſwer the benevolent intentions of thoſe who firſt cultivated it. It makes an impenetrable and beautiful fence. The ſmaller ſtems are made into hoops [c].

Both the bark and gum are gentle ſubaſtringents; but the laſt excels, and adds a ſweetneſs to its virtue, which makes it more agreeable to the palate [d].]

PROPAGATION AND CULTURE.

The ſeeds are frequently brought from America, which, if freſh, readily grow when ſown upon a good hot-bed; and if the plants are kept in a moderate hot-bed, they will grow to be upwards of a foot high the ſame year, and, while the plants are young, they are generally well furniſhed with leaves; but afterwards they make but little progreſs, and are frequently but thinly clothed with leaves. Theſe plants are very tender, ſo ſhould be conſtantly kept in the bark-ſtove, where, if they are duly watered, and the ſtove kept to a good degree of heat, the plants may be preſerved very well.

[In the Weſt Indies it thrives beſt in low ſwampy lands, or ſhallow waters, where the bottom is rich and moderately firm [e].

2. Halesia diptera. *Two-winged Halesia.*
Lin. spec. 636. *Reich.* 2. 417. *Ellis in philos. transf. t.* 22. *f.* B.
Leaves ovate, petioles smooth and even.

DESCRIPTIONS, *&c.*

1. This frequently comes up with two or three ſtems, from fifteen to twenty feet high, ſending out branches towards their tops. Leaves ſerrate, ſharp-pointed, with the middle depreſſed, growing alternately on ſhort foot-ſtalks. The flowers hang in ſmall bunches all along the branches, each gem producing from four to eight or nine; they are of a pure ſnowy whiteneſs; and as they blow early in the ſpring, before the leaves appear, and continue for two or three weeks, they make a moſt elegant appearance. They are followed by pretty large four-winged fruit, hanging likewiſe in bunches, and very agreeable to the taſte[f].

The fruit is a juiceleſs drupe, of an oblong obovate ſhape, four-ſided, finiſhing at top in the ſtyle, at bottom in a very long peduncle: bark thin, fungous and membranaceous, drawn out into four ſtiff lateral wings: ſhell bony, obovate, ſharp-pointed at each end, within empty or having a ſcurfy fungous ſubſtance in the middle, and four cells with a ſeed in each, incloſed all round in the periphery. The ſeeds are fixed to the bottom of the cells, and are oblong, a little bent, and of a pale colour[g].

Native of South Carolina, growing commonly along the banks of Santee river, and ſometimes more ſoutherly. The wood is hard and veined; and the bark of a darkiſh colour, with many irregular ſhallow fiſſures[h].

It flowers in april and may. Introduced in 1756, by John Ellis, Eſq.[i] from ſeeds ſent over by Dr. Alexander Garden, phyſician at Charleſtown[k].

2. The leaves of this are ſix times the ſize of the foregoing, nor are they all tomentoſe underneath. Fruit mucronate, with two large wings oppoſite to each other, and two minute ones[l].

Received by John Ellis, Eſq. from Governor Ellis of Georgia, and ſent to him by Mr. De Brahme, from Auguſta in Georgia, three hundred miles up the river Savannah[m].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, when they can be procured freſh from the places of their natural growth. Theſe ſhould be ſown in pots as ſoon as the ſeeds arrive, plunging the pots into the ground, in a ſituation where they may have only the morning ſun. The ſeeds often remain a year in the ground, therefore the earth in the pots ſhould not be diſturbed, until there is no probability of the ſeed growing. When the plants appear they ſhould be ſcreened from the ſun, and frequently, but not too plentifully watered; for while the plants are young, much moiſture will rot their ſtalks. The following autumn, the pots ſhould be placed in a common frame, where the plants may enjoy the free air in mild weather, and be ſcreened from froſt. The ſpring following, before the plants begin to ſhoot, they ſhould be each put into a ſeparate ſmall pot, plunging them in a frame, where they ſhould be ſhaded from ſun; and in the ſummer placed in a ſhady ſituation, ſcreening them in winter; and the ſpring following they may be turned out of the pots, and planted in the full ground where they are deſigned to remain.

[β. H. fol. lanceolatis ovatis ſuperne ſerratis. *Roy. lugdb.* 289. *Burm. afr.* 243. *t.* 89. *f.* 1.].

DESCRIPTION, *&c.*

This plant grows to the height of ſix or eight feet, with a woody ſtem well furniſhed with branches. Leaves ovate, ſerrate, oppoſite, and continuing green through the year; the flowers come out ſingly, and are of a red colour, but being intermixed with the leaves, and growing ſcatteringly on the branches, are not eaſily diſcerned. They come out in june, and the ſeeds ripen in ſeptember. The leaves continuing green all the winter, this plant makes a good variety in the greenhouſe during that ſeaſon.

[It is a native of the Cape of Good Hope; flowers from june to auguſt, and was cultivated by Mr. Miller in 1752[*].]

PROPAGATION AND CULTURE.

It may be propagated by cuttings, which if planted in pots filled with light earth in june, will ſoon take root. The plants may be expoſed in ſummer, and will require plenty of water at that ſeaſon: in winter they muſt be houſed with Myrtles, and other hardy exotic plants, which require much air in mild weather.

Tetragonia ivæfolia. *Lin. ſyſt.* 467. *ſuppl.* 257.
Leaves ſerrate, flowers in whorls.

DESCRIPTION, *&c.*

1. Branches four-cornered, ſmooth. Leaves oppoſite, ſeſſile, tapering at the baſe into the inſertion, waved, ſmooth. Fruits axillary, ſolitary, pedicelled. When the fruit is in a ſtate of maturity, this plant bears a great reſemblance to Ammannia latifolia[a].

Native of Botany iſland, near New Caledonia, ſeptember 30, 1774: in the iſle of Pines, &c. in the South ſeas.

2. This is an undershrub, with much of the appearance of *Præſium majus*. It is about two feet high, branched, panicled, upright. Stalk quadrangular and red; the angles elevated, rounded, ſcabrous. Leaves oppoſite, petioled, horizontal, ovate-lanceolate, unequally ſerrate; with the ſerratures prickly; ſcabrous, flat, veined, an inch in length; petioles one-third of the length of the leaves, ſemicylindric, channelled. Flowers at the ends of the branches, axillary, in threes, pedunculed, ſmall, reddiſh green. Peduncles ſhort, round, ſcabrous, reflected below the leaves after flowering-time. Petals lanceolate, wider in the middle, ſtanding out between the leaflets of the calyx, ſpreading very much, longer than the calyx, caducous[b]; pale purple. Pericarp white; nut black. When other circumſtances agree, the fruit being quadrangular-winged or without angles, is not ſufficient to conſtitute a generic difference[c].

Found abundantly in New Zealand by Sir Joſeph Banks, Bart, and others. The younger Linneus informs us that it flowered with him in november 1779; and that ſome of the flowers had petals, others none.—With us it flowers moſt part of the ſummer, and was introduced in 1772[d].]

[a] Linn. ſuppl. [b] Ibid. [c] Jacqu. miſc. [d] Hort. kew.

DESCRIPTION, *&c.*

This has a woody ſtem, from two to three feet high, ſending out many ſlender branches. Leaves oval, indented on their edges, having great reſemblance to thoſe of the Hazel, and placed alternately on the branches; theſe fall away in autumn, and then the flowers come out in cluſters from the joints; they are not followed by ſeeds in this country.

[It ſeems to be polygamous, for in Virginia it is dioecous, with axillary, pedunculed, crowded, petaloid flowers; in Carolina it is monoecous, with terminating, many-ſtamened, aculeous flowers, in ſpikes. Whether theſe are diſtinct ſpecies or not, may be doubted; ſince they are ſo very much alike in the herb[e].

In New England, the germ endures the ſeverity of their winters, and the fruit does not ripen till the ſeptember ſucceeding, when ripe fruit and freſh bloſſoms will be found on the ſame tree.

The Indians conſider this tree as a valuable article in their materia medica. They apply the bark, which is ſedative and diſcutient, to painful tumours and external inflammations. A cataplaſm of the inner rind is found to be very efficacious in removing painful inflammations of the eyes[f].

It was introduced in 1736, by Peter Collinſon, Eſq[g].]

PROPAGATION AND CULTURE.

This is propagated by laying down the young branches in autumn, which will take root in one year, provided they are duly watered in dry weather; but many of the plants which are in the gardens, have been produced from ſeeds which came from America: theſe ſeeds always remain a whole year in the ground, ſo they ſhould be ſown in pots, which may be plunged into the ground in a ſhady part of the garden, where they may remain all the ſummer, and require no other care but to keep the pots clean from weeds, and in very dry weather to water them now and then; in autumn the pots may be removed to a warmer ſituation, and plunged into the ground under a warm hedge; and if the winter ſhould prove very ſevere, they ſhould have ſome light covering thrown over the pots, which will ſecure the ſeeds from being deſtroyed. In the ſpring the plants will come up, therefore as the ſeaſon grows warm, the pots may be removed where they may have the morning ſun to eleven o'clock; and if they are duly watered in dry weather, the plants will have made good progreſs by autumn, when they ſhould be tranſplanted, either into ſmall pots, or in a nurſery-bed, where in one, or at moſt two years time, they will be ſtrong enough to plant where they are deſigned to remain; they love a moiſt ſoil, and a ſhady ſituation.

[HAMADAMANIAS. See *Grewia.*]

HAMELIA. *(So named from Jean Baptiſte du Hamel the Monceau, the celebrated author of ſeveral valuable books on Trees.)*
Lin. gen. n. 232. *Reich.* 249. *Schreb.* 205. *Jacqu. amer.* 71. *Juſſ.* 207.

H. ventricoſa. *Swartz prodr.* 46.

Racemes terminating and axillary, leaves ternate, levigated, tube of the corolla bellying.

3. Hamelia axillaris.

Swartz prodr. 46.

Subherbaceous, racemes axillary; flowers moſtly directed one way, ſeſſile; leaves ovate-lanceolate.

4. Hamelia Chryſantha.

Swartz prodr. 46. *Brown jam.* 166. 2. *t.* 14. *f.* 1. (Campanula). *Plum. ic.* 218. *f.* 1. (Periclymenum).

Racemes terminating, leaves oblong, wedge-ſhaped, acuminate, very ſmooth, flowers pedicelled.

DESCRIPTIONS, &c.

1. This is a ſhrub or ſmall tree] growing five or ſix feet high. [Branches diverging, ſpreading, round, ſmooth. Leaves uſually ternate (but ſometimes there are four or five leaflets on a petiole,) ovate, acuminate, entire, nerved, the upper ſurface pubeſcent, hoary on the back, villoſe, ſoft, coloured about the edge. Petioles coloured, the midrib red. Stipules in pairs, within the petioles, awl-ſhaped. Racemes ſpreading, red; the ſubdiviſions trichotomous; flowers directed one way, ſubſeſſile, diſtant, bright red or ſcarlet; there is one ſolitary flower, ſeſſile at the ſubdiviſions. Calyx five-toothed, coloured. Berry black[a].

Native of Hiſpaniola, where Swartz has obſerved it, in hedges on the mountains. Mr. Miller cultivated it in 1768.] He ſays that the ſeeds were brought from Senegal by Adanſon, and that Houſtoun found it in America.

2. This grows to be a large and ſtately tree, affording very broad boards for tables or cabinets, of the ſoftneſs and grain of elm, whence the name of *Spaniſh Elm*, having many undulated light brown or gray lines in it. The cabinet makers, who uſe it very much, call it *Prince-wood*. The bark is aſh-coloured, and very ſmooth. The ends of the branches are beſet with leaves two inches long, and one broad in the middle, from whence they decreaſe in breadth to both extremes; they are ſmooth, not ſerrate, of a freſh green colour, and ſet on foot-ſtalks three-quarters of an inch long. The flowers ſtand ſeveral together; they are large, from a narrow baſe opening wider, almoſt like a bell-flower, of a ſulphureous colour, or like the yellow flowers of the Marvel of Peru. It is ſent to Europe in great quantities for the uſe of cabinet-makers, &c. and when young it makes good hoops[b].

It is native of Jamaica, Hiſpaniola, and other parts of the Weſt-Indies.—It flowers here from ſeptember to november; and was introduced in 1778, by Thomas Clark, M. D[c].

3. Native of Jamaica and Hiſpaniola[d].

4. This is a native of Jamaica. According to Browne, the ſize and the different diſpoſitions of their leaves make the whole difference between this and the ſecond ſpecies.] The height ſeldom exceeds four feet. The flowers are yellow, and the leaves entire.]

PROPAGATION AND CULTURE.

1. This plant is propagated by ſeeds, when they can be procured freſh from the countries where it grows naturally; theſe ſhould be ſown in ſmall pots, and plunged into a moderate hot-bed; the plants generally appear in about five or ſix weeks after, and ſhould then be treated in the ſame way as other plants from the ſame countries; giving them proper air in warm weather, and gently refreſhing them with water; and when they are fit to tranſplant, they ſhould be each planted in a ſmall pot plunging them into the hot-bed again, where they ſhould be ſhaded from the ſun until they have taken new root, when they ſhould have air and moiſture according to the warmth of the ſeaſon. In the autumn the plants muſt be removed into the tan-ſtove, plunging the pots into the bed, where they ſhould be always continued; this flowers in july and auguſt, when it makes a pretty appearance.

As the ſeeds of this plant are ſeldom brought to England, ſo the plant may be propagated by cuttings, which if planted in ſmall pots, plunged into a moderate hot-bed, and cloſely covered with either bell or hand-glaſſes, will put out roots in about ſix weeks, and may then be treated in the ſame way as the ſeedling plants.

Claſſ. 5. 2. Pentandria Digynia.

Nat. order of *Umbelliferæ.*

GENERIC CHARACTER.

CAL. *Umbel* ſpreading. *Umbellules* ten, five of which are in the circumference.—The rudiment of the central umbellule is a mortified vitiated body, pedicelled, ſomewhat three-ſided, fleſhy, depreſſed, dark-coloured, hoary above, with white hairs.—*Involucre* very ſmall, five-leaved, ſubulate, reflex. *Involucels* halved; thoſe of the outer ones three-leaved, ſubulate, nodding, ſhorter than the umbellule.—Umbel when fruit-bearing converging.

COR. *Flowers* radiate, even of the inner umbellules. *Floſcules of the ray* hermaphrodite; petals unequal, bowed in and bifid, the outmoſt petal two clefts, and the next ſingle one large, (ſo that in each corollule there are four clefts large, and ſix ſmall). *Floſcules of*

[a] Swartz. [b] Sloane. [c] Hort. kew. [d] Swartz.

[e] Linn. ſuppl.

the

the inner disk male: petals nearly equal, bowed in and bifid (all the clefts small).

STAM. *Filaments* five to all the floſcules, longer than the ſmaller petals. *Anthers* roundiſh.

PIST. *Germ* inferior. *Styles* filiform, permanent. *Stigmas* obtuſe.

PER. none.

SEEDS *outmoſt* double, oval, ſmooth, the edge thicker, crenulate. *Inner* ſolitary, hemiſpherical, drooping, pitcher-ſhaped, with the ſide hollow; theſe alſo are furniſhed with two ſtyles.

In the inner diſh none.

ESSENTIAL CHARACTER.

Cor. radiated, in the diſk male. *Seeds* in the circumference double, with a notched edge: in the diſk ſolitary, pitcher-ſhaped, hemiſphærical. (outer orbiculate, flat, inner bullate. *G.*)

SPECIES.

Lin. ſyſt. 275. *ſuppl.* 179. *Jacqu. hort.* 2. 91. *t.* 193. *Gærtn. fruct.* 85.
Leaves heart-ſhaped.

DESCRIPTIONS, *&c.*

1. Root fuſiform, ſmaller than the finger, white, annual. Stem a foot and half high, upright, round, white, with rough hairs, finally muricate-ſcabrous. Branches from the upper axils, ſimple. Leaves alternate, remote, petioled, toothed, blunt, ſcabrous underneath, on the ribs. Petioles ſcabrous. Sheath bellying, woolly white at the baſe, and on the upper edge, purple on the lower edge. Umbels of flowers at the top of the ſtem, and at the ends of all the branches. Peduncle five-cornered, muricate. Corolla white. Anthers greeniſh. Stamens and ſtyles white [a].

The outer ſeeds are of a pale ſtraw-colour. The inner are naturally double as well as them, but one is conſtantly abortive, and adheres to the inner ſide of the other near the top, in form of a withered ſcale; the other as it grows, turns into a membranaceous bulla, opening on the inner ſide by a large fungous hole ſurrounded with a crenulate margin, and has only a ſingle embryo in it [b].

Native of Egypt.—Cultivated in 1768, by Mr. Miller. It flowers in july [c].

2. Annual. Stem upright, flexuoſe, a little ſtreaked, hairy at bottom. Lower leaves ternate: the ſide leaflets ſubſeſſile, ovate, crenate, that at the end petioled, cordate, crenate, obtuſe: upper leaves cordate, ſimple. Involucre of many reflex briſtles, ſhorter by half than the corolla: involucels briſtle-ſhaped, the length of the flowers. Umbel copious, flat, white, without the central body. Marginal petals of the umbellules two, larger, flat, obovate; the reſt nearly equal, ſmall, ovate, entire [d]. Seeds very like thoſe of the foregoing, but much ſmaller: thoſe in the ray membranaceous and compreſſed, ſurrounded with a ſmooth, narrow, white rim, and within that of a dirty ferruginous colour: thoſe in the centre ovate-bullate, ferruginous bay colour on the back, ſurrounded at the aperture with a thickened, ſmooth, white rim [e].

It varies with all the leaves ſimple and ternate [f], Introduced in 1787, by Mr. Ziet [g].

PROPAGATION AND CULTURE.

Theſe plants are biennial, and being natives of warm countries, are with difficulty preſerved in England; for when the plants come up early in the ſpring, they do not perfect their ſeeds the ſame year; and thoſe plants which ariſe in the autumn, ſeldom live through the winter; the ſureſt method therefore to procure good ſeeds in this country, is to ſow the ſeeds in pots about the middle of auguſt, placing the pots where they may have the morning ſun only, being careful to water them duly, to weed and thin them. In october remove the pots into a common frame, where they may enjoy the free air in mild weather, but be ſcreened from froſt. The ſpring following, if the plants are carefully turned out of the pots, and planted in the full ground, they will flower in june, and the ſeeds will ripen in auguſt.

Leaves lanceolate, toothed, ſmooth, bractes entire, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

1. Stalk upright, a foot high, with ſimple aſcending branches next the root, and under the ſpike. Leaves alternately ſcattered, ſomewhat hiſpid, upright, with copious

copious leaflets branching a little from each axil. Spike terminating, ſeſſile, oblong, barren at bottom; with ſmooth bractes, awl-ſhaped, imbricate in ten longitudinal rows, one to each flower; for the ſpike is conſtructed of five-flowered whorls, but alternate. Corolla white, with a red throat; ſingular in having the ſtamens placed on the very edge of the fiſſure [a]:—the lip widens outwards, and is three-lobed at the end, the middle lobe bifid, the ſide ones emarginate. Capſule ovate-acuminate, ending with the ſtyle, ſomewhat membranaceous, compreſſed like a lens. Seeds ſubelliptic, acuminate at the tip, ſlightly emarginate at the baſe, pale ſtraw-colour, fixed to the bottom of the capſule without any receptacle [b].—The flowers in the morning are without ſcent, at noon they are ſtinking and nauſeous, in the evening ambroſiac, like the Oriental Hyacinth [c].

Native of the Cape of Good Hope. Biennial. Flowers here from february to november. Introduced in 1770, by Monſ. Reichard [d].

2. 3. Both theſe bear a great reſemblance to the foregoing; and the third ſeems only to be a variety of the ſecond. They are both natives of the Cape.

4. An underſhrub. Stem upright, whitiſh, ſmooth and even, ſparingly branched only at top. Leaves alternate or oppoſite, ſeſſile, or ſomewhat ſtem-claſping, blunt, ſcarcely crenate, gibbous underneath. Spike terminating, ſeſſile. Corolla white, with a fleſh-coloured throat. Anthers compreſſed, yellow, as in H. dentata [e].—Native of the Cape, and introduced in 1774, by Maſſon [f].

5. 6. Found at the Cape by Thunberg.]

DESCRIPTIONS, *&c.*

1. Common Ivy is a parafitical ſhrub.] Where it meets with any ſupport, ſuch as walls, buildings or trees, the ſtem will adhere to them, and riſe to a very great height, inſinuating itſelf by a great abundance of fibres into the joints of walls, or the bark of trees. If no ſupport is near, the ſtalks trail upon the ground, taking root their whole length, ſo that they cover the ſurface cloſely, and are difficult to eradicate; for where any ſmall parts of the ſtalks are left, they will ſoon ſpread and multiply. Whilſt Ivy is fixed to any ſupport, or trails upon the ground, the ſtalks are ſlender and flexible; but when it has reached to the top of its ſupport, they ſhorten and become woody, forming themſelves into large buſhy heads; their leaves are larger, more of an oval ſhape, and not divided into lobes like the lower leaves: this difference occaſioned the old botaniſts to take them for different ſpecies. Whilſt the ſtalks trail, Ivy does not produce any flowers; and in this ſtate it is called *Barren* or *Creeping Ivy*: but when the branches get above their ſupport, they produce flowers at the end of every ſhoot; theſe are ſucceeded by berries, formed into round bunches called by the ancients *corymbi*, and turning black before they are ripe. [In this ſtate it is called *Climbing* or Berried Ivy.—The trunk in old trees is covered with an aſh-coloured chopped bark; in the young branches it is of a green or purple colour. Leaves alternate, evergreen, gloſſy, ſmooth, while the plant creeps, three-lobed or ſometimes five-lobed; but when it quits its ſupport, ovate: they are ſometimes tinctured with red, ſometimes painted with white veins, particularly in the young branches. The petioles are long, and dilated at the baſe. The flowers are yelloviſh, or greeniſh white, in a very cloſe, thick umbel, at the extremities of the twigs [a].—The berry is placed below the receptacle of the flower, and is crowned with the five-cornered, ſtreaked rudiment of it; at firſt it is ſucculent, with a purple juice; afterwards it becomes coriaceous, dry, and very obſcurely quinquangular. The five cells are inverted by their proper ſilky-white membrane: the partitions are very thin, one or more frequently obliterated when the berry is in a ſtate of maturity. The ſeeds are wrinkled and yelloviſh [b].

It is found wild all over Europe; but Linnæus ſays it is by no means common in Sweden. Kalm remarks, that he never ſaw the common Ivy in North America, except once, againſt a ſtone building, and this was apparently brought from Europe, and planted there [c]. Thunberg remarked it in Japan, and ſays that the leaves are commonly undivided there, and not lobed. It begins to flower with us in ſeptember. Being ſo late a blower, it is much reſorted to by bees and flies, when little other food is to be had. The berries increaſe during the winter, are full formed in february, and ripen in

[a] Curtis, Juſſieu, Krocker. [b] Gærtner. [c] Travels, 1. 141. Engl. edit.

april; furniſhing food for wild pidgeons, black-birds, thruſhes, &c. in the ſpring. Black-birds and ſeveral other birds build their neſts in the ſtump. Sheep are fond of Ivy; it is a warm and wholeſome food for them in hard weather, the ſhepherds therefore in ſnowy ſeaſons cut down branches for their flocks to browze on. Cato directs that in a ſcarcity of hay, cattle ſhould be foddered with it. The ancients held Ivy in great eſteem. It formed the poetical garland.

" Inter victrices *hederæ* tibi ſerpere lauros."

Bacchus is repreſented crowned with it to prevent intoxication: and Homer deſcribes his heroes as drinking out of a cup made of the wood [d].

As a medicine it is ſcarcely admitted into modern practice. The leaves have a nauſeous taſte. Haller ſays they are given in Germany as a ſpecific in the atrophy of children. Common people apply them to iſſues and corns. The berries have a little acidity. They purge and vomit [e]. In Gallicia they give the ſeeds bruiſed in pleuriſies, to the quantity of two teaſpoonfulls, every eight hours [f]. In warm climates a reſinous juice exſudes from the ſtalks [g]; or may be procured by wounding them. It is inſipid and inodorous, inflames in burning, with a pleaſant aromatic ſmell, and has then a ſlight aſtringency. It tinges ſpirit of wine of a reddiſh brown colour, and is ſaid to be aperient, reſolutive and balſamic: but it is not in uſe [h].

The wood is ſoft and porous, ſo as to tranſmit liquids, if turned of a ſufficient degree of thinneſs. The roots are uſed by leather-cutters to whet their knives upon. The branches, being very full of leaves; are as effectual as any thing to protect the tender bloſſoms of apricots, peaches and nectarines, againſt the cold winds and froſts of february and march [i].]

In the latter part of the laſt century, when it was the faſhion to fill gardens with all ſorts of sheered evergreens, many of theſe plants were trained into round heads, clipped into globes cones, &c.; and being ſo hardy as not to be injured by weather, and growing in any ſoil, were then much eſteemed: ſince this taſte has been exploded, the Ivy is ſeldom admitted into gardens, unleſs to cover walls, or run over ruins, &c. for which purpoſes no plant is ſo well adapted.

[Mr. Curtis, however obſerves that few people are acquainted with the beauty of Ivy when ſuffered to run up a ſtake, and at length to form itſelf into a ſtandard: the ſingular complication of its branches, and the vivid hue of its leaves, give it one of the firſt places amongſt ever-greens in a ſhrubbery. In woods, when ſuffered to grow large and rampant, this plant, by twining round the bodies of timber trees, does them great damage, and therefore ſhould be carefully deſtroyed, as it may eaſily be, by cutting any where through its trunk. But in ornamental outlets, where ever-greens do not abound, a few trees covered with Ivy have a very pleaſing effect; and induce birds of ſong to haunt thoſe thickets for the ſake of the berries and ſhelter. Ivy alſo produces very picturesque effects in large maſſes of ruined buildings. Linneus affirms that it does no injury to buildings; but that can ſcarcely be admitted, when we conſider that it muſt harbour wet and filth, and that the branches will make their way into any fiſſure or deſect in the wall, and inlarge it.

Beſides the varieties enumerated above, which ariſe merely from age and ſituation, there are two that may be found in the nurſeries: [k] one with ſilver-ſtriped leaves, and the other with yellowiſh leaves on the top of the branches.

2. Stem arboreſcent, eight feet high in the ſtove, erect, cylindrical, abruptly branched. Bark brown, a little cracked. Branches curved upwards, leafy, terminated by flowers. Leaves ſcattered, more crowded towards the tops of the branches, on foot ſtalks, wide ſpreading, pointed, waved on the margin, very ſmooth, obſcurely three-nerved, veiny, bright green. Foot-ſtalks various in length, nearly cylindrical, ſmooth firmly fixed to the branch by an enlarged triangular baſe. Buds conſiſting of ſeveral large, roundiſh, ſmooth, yellowiſh ſcales, ſoon falling off, which are often tipped with the rudiments of a leaf, and appear like abortive leaves. Racemes erect, branches generally alternate, ending in little round heads of many ſeſſile flowers. Common foot-ſtalks obſoletely angular, pale green, ſprinkled with ruſty-coloured powder; partial ones cylindrical. Bractes ſolitary at the baſe of the latter, ſmall, concave, pointed, entire, powdery. Flowers numerous, white, ſo ſmall that the ſtructure is not readily to be underſtood; each ſtands on its proper involucre, reſembling a calyx of one leaf, in five diviſions, externally powdery, permanent. Calyx pale green, ſmooth, permanent. Petals on the margin of the calyx, ovate, ſomewhat pointed, white, deciduous. Filaments oppoſite to the teeth of the calyx, and alternate with the petals, ſpreading, white. Anthers roundiſh, two-lobed, yellow. Germen below the flower, crowned with the calyx, roundiſh, ſmooth. Styles ſhort erect, at firſt united into one body, then ſpontaneouſly ſplitting into ſeveral, varying in number from three to ten. Berry ſmooth, brown, with five or more cells, each probably containing one ſeed.

Jacquin, the firſt diſcoverer, long ago ſuſpected, that this ſpecies belonged to the genus Hedera or Ivy; but later authors have kept it in that of Aralia.

This fine plant was diſcovered in the woods of Martinico, by Profeſſor Jacquin, and in Jamaica by Dr. William Wright and Mr. Francis Maſſon. (In the catalogue of the Royal garden at Kew, it is ſaid to have been introduced in 1778, by Mr. William Forſyth, but) it exiſted in the collection of the late Marquis of Rockingham long before the year 1777. It flowered for the firſt time in Europe in the ſtove of the Marchioneſs in 1787 [l].

3. Racemes triſid, twice dichotomous, finally umbelled. Calyx very ſhort, bluntly toothed, red at the tip. Petals blunt, arched at the tip, green. Gland of the receptacle higher than the calyx, ſurrounding the germ with a few notches. Filaments ſubform, a little longer than the corolla. Style of the ſame length with the filaments. Germ ſuperior, containing four ſeeds. The number varies in the flower, being either four or five [m].]

It grows naturally in all the northern parts of America, was firſt brought to Europe from Canada, and has been chiefly employed to cover walls or high buildings, which this plant will do in a ſhort time, for it will ſhoot almoſt twenty feet in one year; but as the leaves fall off in autumn, and are late before they come out in the ſpring, it is not much eſteemed, unleſs where better things will not thrive; not being injured by ſmoke, or cloſeneſs of air, it is proper to cover buildings in great towns. The ſtalks put out fibres, like the common Ivy, which inſinuate themſelves into the joints of walls.

[From Parkinſon it appears that it was cultivated here in 1629.

Juſſieu is of opinion that it ſhould be removed to the genus Vitis or Vine.

4. 5. Natives of Jamaica [n].

6. The whole is ſmooth. Branches round, ſubherbaceous, the thickneſs of a ſwan's quill. Leaflets petioled, umbelled, from three to four inches long, the ſide ones gradually leſs, ſomewhat veined, ſometimes ending in a ſhort point. Petioles a ſpan long, round, embracing with the widened baſe; the middle petiolules two inches long; the ſide ones ſhorter. Raceme terminating, on the ſide of the leafy branch, compound: general pedunce three inches long, the thickneſs of a ſwan's quill; the partial ones in fives, alternate, the two laſt conjugate, half a foot long, ſpreading. Calyx a very ſhort entire rim. Petals ſix, linear. Stamens ſix, the length of the corolla. Style the length of the filaments. Native of Ceylon [o].]

PROPAGATION AND CULTURE.

The different species are easily propagated by their trailing branches, which send forth roots their whole length; or by cuttings, planted on a shady border in autumn, which by the following autumn will be fit to plant where they are designed to remain; or by seeds sown soon after they are ripe, which is in the beginning of April: if these be kept moist and shaded, they will grow the same spring, otherwise they will remain a year in the ground.

HEDERA TERRESTRIS. See *Glechoma*.

[HEDGE-HYSSOP. See *Gratiola*.

HEDGE-MUSTARD. See *Sisymbrium* & *Erysimum*.

HEDGE-NETTLE. See *Galeopsis*.]

HEDGES. Hedges are either planted to make fences round inclosures, or to part off and divide the several parts of a garden: when they are designed as outward fences, they are planted either with Hawthorn, Crabs, or Black-thorn, which is the Sloe; but those Hedges which are planted in gardens, either to surround wilderness quarters, or to screen the other parts of a garden from sight, are planted with various sorts of plants, according to the fancy of the owner; some preferring ever-green Hedges, in which case the Holly is best, next the Yew, then Laurel, Laurustinus, Phillyrea, &c. others, who make choice of the deciduous plants, prefer the Beach and Hornbeam, English Elm, or the Alder, to any other: I shall first treat of those Hedges which are planted for outside fences, and afterwards briefly touch on the other.

These Hedges are most commonly made of Quick, (i. e. White-thorn,) yet it will be proper, before planting, to consider the nature of the land, and what sorts of plants will thrive best in that soil, whether it be clay, gravel, sand, &c. likewise what the soil is from whence the plants are to be taken; for if the land they are taken from is much better than that in which they are to be planted, it will be more difficult to get them to grow. As for the size, the sets ought to be about the bigness of a goose quill, and cut within about four or five inches of the ground; they should be fresh taken up, straight, smooth, and well rooted. Those plants which are raised in the nursery, are to be preferred to all others, and if raised on a spot near the place, it will be best. The time for planting is february, march and april.

Secondly, if the Hedge has a ditch, it should be made six feet wide at top, and one foot and a half at bottom, and three feet deep, that each side may have a proper slope; for when the banks are made too upright, they are very subject to fall down after every frost or hard rain; besides, if the ditches are made narrower, they are soon choked up in autumn by the falling leaves, and the growth of weeds, nor are they a sufficient fence to the Hedge against cattle, where they are narrower.

Thirdly, if the bank be without a ditch, the sets should be set in two rows, almost perpendicular, at the distance of a foot from each other, in the quincunx order, so that in effect they will be but six inches asunder.

Fourthly, The turf is to be laid with the Grass side downwards, on that side of the ditch the bank is designed to be made, and some of the best mould should be laid upon it to bed the Quick; then the Quick is to be planted upon it a foot asunder, so that the ends of the Quick may stand upright.

Fifthly, When the first row of Quick is planted, it must be covered with mould, and the turf laid upon it as before; so that when the bank is a foot high, you may plant another row of sets against the spaces of the lower Quick, and cover them as the former was done; and the bank is to be topped with the bottom of the ditch, and a dry, or dead Hedge laid on the other side, to defend the tender plantation from the cattle.

In making of these dead Hedges, there should be stakes driven into the loose earth, at about two feet and a half distance, to low as to reach the firm ground.

Oak stakes are accounted the best, and Black Thorn and Sallow the next; then let the small bushes be laid at bottom, but not too thick, for that will cause the bushes to rot; but the upper part of the Hedge should be laid with long bushes to bind the stakes in with, by interweaving them.

And, in order to render the Hedge yet stronger, you may edder it, as it is called, i. e. bind the top of the stakes in with some small long poles, or sticks on each side; and when the eddering is finished, drive the stakes anew, because the waving of the Hedge and eddering is apt to loosen the stakes.

The Quick must be constantly kept weeded, and secured from being cropped by the cattle, and in february it will be proper to cut it within an inch of the ground, if it was not done before; which will cause it to shoot strong, and help it much in the growth.

When a Hedge is of about eight or nine years growth, it will be proper to plash it; the best time for this work is either in october or february.

When a Hedge is grown old, i. e. of about twenty or thirty years growth, and there are in it old stubs as well as new shoots, the old stubs should be cut sloping off within two or three inches of the ground, and the best and longest of the middle size should be left to lay down; and some of the strongest, at the height of five or six feet, according as you design the height of the Hedge to be, may be left to serve instead of stakes, and fresh stakes should be put in those places where they are wanting; the Hedge should be then thinned, so as to leave on the stubs only such shoots as are designed to be of use, that there may be room left to put a spade in between them; the ditch also should be cleansed, and each side of the slopes kept as in a new ditch; and where the earth is washed from the roots of the Quick, or is hollow, face it anew with so much of the first spit of earth that is dug out of the ditch, as there is occasion for, and lay what is dug out at the second spit, on the top of the bank, for if it be laid on the side, or face of the bank, it will slip into the ditch again when wet comes, and also take a great deal of the bank along with it.

In plashing Quicks, there are two extremes to be avoided; the first is, laying it too low and too thick; because it makes the sap run all into the shoots, and leaves the plashes without nourishment, which with the thickness of the Hedge, kills them.

Secondly, It must not be laid too high, because this draws all the sap into the plashes, and so causes but small shoots at the bottom, and makes the Hedge so thin, that it will neither hinder the cattle from going through, nor from cropping of it.

When the shoot that is designed to be plashed is bent, give it a small cut with a bill, half through, sloping a little downwards, and then weave it about the stakes; and when the whole is finished, trim off the small superfluous branches that straggle too far out on both sides of the Hedge.

If the stubs are very old, cut them quite down, and secure them with good dead Hedges on both sides, till the young shoots are got up tall enough to plash, and plant new sets in the void spaces.

In making a Hedge, if it be set with Crab Stocks, it will be proper to leave one standing uncut up at every thirty or forty feet, if the ground on both sides of the Hedge be your own; which being done, they may be so ordered, by pruning or staking, that one may lean into one ground, and the other into another, &c.

These stocks should be pruned up every year, till they are brought out of the reach of the cattle, and then they may be grafted with the Red Streak, Gennet-moyl, or what other kind of cyder apple you please.

If the stocks be of Apple kernels, they may stand ungrafted, for many of them will yield very good cyder fruit; but then such stocks as are not grafted, will be longer before they bear; and also when you do graft, you may be certain of your kind; but if you find a very natural stock, which by leaf, shoot, and bud, appears likely, you may try it, and so you may have a new fine fruit; and if you do not like it, you may graft it when you please.

As for the rest of the Hedge, when it has shot four or five years, you may lay it to make a fence; for the doing of which take the following directions:

First, At every laying to lay down ſome old plaſhes; or, if the Hedge be thin, young ones; but they muſt be ſo laid, as to point with their ends to the ditch ſide of the bank, the ends being kept low on the bank; by being ſo ordered, they will the better thicken the bottom of the Hedge, and keep up the earth of the bank.

Secondly, To heighten the bank every time you lay earth on it, ſo as to cover the layers, all but the ends, this earth will very much help the Quick; and by heightening the banks, and deepening the ditch, you will render the fence the better.

Thirdly, Not to cut the plaſhes too much, but juſt ſo as they may bend down well; not to lay them too upright, as ſome do, but to lay them near to a level; for by ſo doing, the ſap will the better break out at ſeveral places, and not run ſo much to the ends, as it will when they lie too much upon the ſlope.

If you have much wood to ſpare, you may cut up great part of thoſe that grow near the ditch, but then you ought to hang the bank with buſhes, to prevent cattle from cropping them the firſt year; theſe will ſhoot ſtrong, ſecure the Hedge, keep up the bank, and thicken the bottom of the Hedge.

Fourthly, Take care to lay the Hedge pretty thick, and turn the beard on the ditch ſide; but you muſt not let the beard hang uncut, though it makes a good ſhew at the firſt making, but you muſt cut off all the ſtraggling boughs within half a foot of the Hedge on both ſides, which will cauſe it to ſhoot ſtrong at theſe places, and make the Hedge much the thicker.

Fifthly, If the bank be high, make the Hedge ſo low, that it may juſt ſerve for a fence the firſt year, for it will ſoon grow higher; and the lower the Hedge is made, the faſter the Quick will grow, and alſo will be the thicker at the bottom; but care muſt be taken to preſerve it from cattle on the field ſide for the two firſt years that it is made.

Sixthly, If you would have a good Hedge, or fence, you ſhould new lay it once in fourteen or fifteen years, and conſtantly root out Elder, Traveller's Joy (which ſome call Bull-bine), Briony, &c. and do not leave too many high ſtandards, or pollards in it, though the Elm is one of the beſt; alſo no dead wood is to be left in the bottom of the Hedges, for that will choke the Quick; but if there be a gap, the dead Hedge ſhould be made at a diſtance.

The Crab is alſo frequently planted for Hedges, and if the plants are raiſed from the kernels of the ſmall wild Crab, they are much to be preferred to thoſe which are raiſed from kernels of all ſorts of Apples without diſtinction: becauſe the plants of the true ſmall Crab never ſhoot ſo ſtrong as thoſe of the Apples, ſo may be better kept within the proper compaſs of a Hedge; and as they have generally more thorns upon them, they are better guarded againſt cattle, &c. than the other; beſides, the plants of the Crab will grow more equal than thoſe which are raiſed from the kernels of various kinds of Apples, for theſe always produce a variety of plants, which differ from each other in their manner of growth, as much as in the ſize and flavour of their fruits; ſo that Hedges made of theſe will not appear ſo well, nor can be ſo well managed as the other.

Some perſons intermix Crab with the White Thorn in their Hedges, but this is not a good method; for the plants of the Crab will grow much ſtronger than thoſe of the White Thorn, ſo that the Hedge will not be of equal growth; which is not near ſo beautiful or uſeful, as when the plants of a Hedge keep pace in their growth.

The Black Thorn, or Sloe, is alſo frequently planted for Hedges, and is a ſtrong durable plant for that purpoſe, eſpecially as it is ſo ſtrongly armed with thorns, that cattle ſeldom care to browze upon it; but where this is planted, the beſt way is to raiſe the plants from the ſtones of the fruit; for all thoſe which are taken from the roots of old trees, ſpawn, and put out ſuckers in ſuch plenty from their roots, as to ſpread over, and fill the neighbouring ground to a conſiderble diſtance on each ſide of the Hedge; and this plenty of ſuckers drawing away the nouriſhment from the old plants of the Hedge, they never grow ſo well as where there are few or no ſuckers produced, which thoſe plants which are propagated from the ſtones ſend not forth, or at leaſt but ſparingly, therefore may with little trouble be kept clear of them. The beſt method of raiſing theſe Hedges is, to ſow the ſtones in the place where the Hedge is intended, where it can be conveniently done, for then the plants will make a much greater progreſs than thoſe which are tranſplanted; but the objection to this method will ariſe from the difficulty of ſecuring the young plants from the cattle; but this can have little force, when it muſt be conſidered that if the Hedge is planted, it muſt be fenced for ſome years, to prevent the cattle from deſtroying it; therefore the ſame fence will do for it when ſown, nor will this require a fence much longer than the other. For the plants which ſtand unremoved, will make a better fence in ſeven years than that which is planted, though the plants ſhould be of three or four years growth when planted; which is what I have ſeen two or three times, where the experiment has been tried. The ſtones of this fruit ſhould be ſown early in January, if the weather will permit; but when they are kept out of the ground longer, it will be proper to mix them with ſand, and keep them in a cool place. The buſhes of the Black Thorn are by much the beſt of any for making of dead Hedges, being of longer duration, and having many thorns; neither the cattle nor the Hedge-breakers will care to meddle with them; theſe buſhes are alſo the beſt to be uſed for under ground drains, for the draining of land, for they will remain ſound a long time when the air is excluded from them.

The Holly is ſometimes planted for Hedges, and is a very durable ſtrong fence; but where it is expoſed, there will be great difficulty to prevent its being deſtroyed, otherwiſe it is by far the moſt beautiful plant, and being an Evergreen, will afford much better ſhelter to cattle in winter, than any other ſort of Hedge; and the leaves being armed with thorns, the cattle will not care to browze upon it. Another objection to this plant is the ſlow growth, ſo that Hedges planted with this plant, require to be fenced a much longer time than moſt others. This is a reaſon which muſt be admitted, to prevent this being generally practiſed; but in ſuch grounds as lie contiguous to, or in ſight of gentlemen's houſes, theſe ſort of Hedges will have an exceeding good effect, eſpecially when they are well kept, as they will appear beautiful at all ſeaſons of the year; and in the ſpring of the year, when the ſharp winds render it unpleaſant to walk abroad in expoſed places, theſe Hedges will afford good ſhelter, as they will effectually keep off the cold winds, if they are kept cloſe and thick. The ſureſt method of raiſing theſe Hedges is, by ſowing the berries in the place where they are to ſtand; but theſe berries ſhould be buried in the ground one year before they are ſown by which method they will be prepared to grow the following ſpring. The way of doing this is, to gather the berries about Chriſtmas, which is the time they are uſually ripe, and put them into large flower-pots, mixing ſome ſand with them; then dig holes in the ground, into which the pots muſt be ſunk, covering them over with earth about ten inches thick; in this place they may remain till the following october, when they ſhould be taken up and ſown in the place where the Hedge is intended. The ground for this Hedge ſhould be well trenched, and cleared from the roots of all bad weeds, buſhes, trees, &c. Then two drills ſhould be made at about a foot diſtance from each other, and about two inches deep, into which the ſeeds ſhould be ſcattered pretty cloſe, leſt ſome ſhould fail; for it is better to have too many plants come up, than to want. The reaſon of my adviſing two drills is, that the Hedge may be thick to the bottom, which in a ſingle row rarely happens, eſpecially if there is not great care taken of them in the beginning. When the plants come up, they muſt be carefully weeded; for if the weeds are permitted to grow among them, they will ſoon deſtroy them, or weaken them ſo much, that they will not recover their ſtrength in a long time. This ſhould be conſtantly obſerved by every perſon

who

who is desirous to have good Hedges of either sort; for when the weeds are suffered to grow near the plants, they will not only rob them of a great part of their nourishment, but also prevent their putting out shoots near the ground, which will occasion the bottom of the Hedge to be thin and naked.

When these Holly Hedges are designed to be kept very neat, they should be sheered twice a year, in may and august; but if they are only designed as fences, they need not be sheered oftener than once a year, which should be about the latter end of june, or the beginning of july; and if this is well performed, the Hedges may be kept very beautiful.

The fences which are made to secure these Hedges from cattle while they are young should be contrived so as to admit as much free air as possible, which is absolutely necessary for the growth of the plants; for when they are crowded on each side with dead Hedges, the plants seldom thrive well. The best sort of fences for this purpose, are those which are made with posts and rails; or instead of rails, three ropes drawn from post to post, and holes made in the posts to draw the ropes through; this is the cheapest fence of this kind, and will appear very handsome: but if sheep are not admitted into the fields, there will be occasion for two ropes only, which will be enough to keep off larger cattle; and if the ropes are painted over with a composition of melted pitch, brown Spanish colour, and oil, mixed well together, they will last sound several years; and these sort of fences never obstruct the air, and the place, at the same time being open to view, the weeds will be better discovered than when the fences are close. In the latter case, the Hedges are sometimes suffered to be over-run with weeds, by their being excluded from the sight, so are frequently forgotten, especially in moist weather, when the weeds grow more luxuriant.

There are some persons who intermix Holly with the White Thorn in making their Hedges, which if rightly managed, will have a good effect, especially when young; but when this is practised, the Holly should be planted so near, as that the Hedge may be entirely formed of it as it grows up, when the White Thorn should be quite rooted out; for as these advance, they will not keep pace in their growth, so will not appear beautiful when intermixed.

When a Hedge of Holly is intended to be made by plants, the ground should be well trenched, as was before advised for the seeds; and unless the ground be very wet, the plants should be set in october; but in wet ground, march is preferable. The plants should not be taken from a better soil than in which they are to be planted; for when it so happens, the plants are much longer before they recover this change, than those are which are taken from a leaner soil. If the plants have been before removed two or three times, they will have better roots, and will be in less danger of miscarrying; besides, they may be removed with balls of earth to their roots. When the frost comes on, if mulch be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may then have been put out, from being destroyed by the cold. I would never advise the planting of Hedges with Holly plants, of above five or six years growth from the berries; for when the plants are older, if they take to grow, they are longer before they form a good Hedge, than plants which are much younger; and if the plants have been twice before transplanted, they will more certainly grow.

I shall next treat of Hedges for ornaments in gardens; these are sometimes planted with Evergreens, especially if they are not intended to grow very high; in which case, they are planted with deciduous trees. Evergreen Hedges are planted with Holly, Yew, Laurel, Laurustinus, Phillyrea, Alaternus, evergreen Oak, and some others of less note. The Holly is preferable to any other, for the reasons before given. Next to this, most people prefer the Yew, on account of its growing very close; for when these Hedges are well kept, they will be so thick as that a bird cannot get through them; but the dead colour of the Yew, renders these Hedges less agreeable. The Laurel is one of the most beautiful greens of any of the evergreen trees, but then it shoots so luxuriant, as to render it difficult to keep the Hedges which are planted with it, in tolerable shape; besides, the leaves being very large, if the Hedge is clipped with sheers, the leaves will be cut through, which gives them a bad appearance; therefore where there are Hedges of this kind, it will be the best way to prune them with a knife, cutting the shoots just down to a leaf. And although by this method the Hedge cannot be rendered so even as when cut with sheers, yet it will have a much better appearance than that of most of the leaves being cut through and stubbed, in the manner they must be when sheered.

The Laurustinus is also a very fine plant for this purpose, but the same objection is to be made to this as hath been to the Laurel; and as one of the great beauties of this plant is in its flowers, which are produced in the winter and spring, so when these are sheered, the flowers are generally cut off, by which their beauty is lost. Nor can this be avoided, where the Hedge is to be kept in close order, therefore this plant is not so proper for the purpose; but in such places where walls or other fences are designed to be hid, there is not any plant better adapted than this, provided it is rightly managed; for the branches of this plant are slender and pliable, so may be trained up close to the fence, whereby it may be entirely covered; and if, instead of clipping these with sheers, they are pruned with a knife, they may be so managed, as to have them full of flowers from the ground upward. This may be effected by pruning them in april, when the flowers are going off, cutting out those shoots that have flowered, or project too far from the fence; always cutting close to the leaf, that no stubs may be left but those new shoots of the same spring must by no means be shortened, because the flowers are always produced at the extremity of the shoots of the same year; therefore when these are topped, as they must be by sheering, there can be few or no flowers upon these plants, except toward the top, where the sheers have not passed. By this method of knife pruning, the leaves will also be preserved entire, and the Hedge may always be kept enough within compass, and so thick, as fully to answer the purpose of covering the fence; and by the shoots growing a little irregular, it will make a much better appearance than any thorn Hedge whatever.

The small leaved and the rough leaved Laurustinus are the best sorts for this purpose, because their branches grow closer together than those of the shining leaved; they are also more hardy, and flower much better than the other, when growing in the open air.

The true Phillyrea is the next best plant for Hedges; it is by the gardeners called the True Phillyrea, to distinguish it from the Alaternus, which they simply call the Phillyrea. The branches of this are strong, the leaves pretty large, and of a strong green colour. And as this is a plant of middling growth, the Hedges planted with this may be led up to the height of ten or twelve feet; and if these Hedges are kept narrow at the top, that there may not be too much width for the snow to lodge upon them, they may be rendered very close and thick, and being a very good green, will make a fine appearance.

The Alaternus was formerly much more cultivated in the English gardens than at present. This was often planted to form Hedges, but the branches of this plant are too pliant for this purpose, being frequently displaced by strong winds, which render these Hedges unsightly; they also shoot very irregular and thin, so that the middle of the Hedge is frequently open and wide, and only the sides of them can be kept tolerably close, and that must be by often clipping them. If we add to this, their being frequently laid or broken down by snow in the winter, it must be deemed an improper plant for this purpose.

The Ilex, or evergreen Oak, is also planted for Hedges, and where these are designed to grow pretty tall, it is a fit plant for the purpose; because it is a plant of large growth, especially the sort which is most common in England; for there are two sorts of them which

which grow in the south of France and Italy, that are of much humbler growth, so are better adapted to this purpose, especially where the Hedge is not intended to be high, but these are not at present common here. When these Hedges are planted very young, and kept close trained from the beginning, they may be very close from the ground to the height of twenty feet or more; but these must always be kept narrower at the top than below, that there may not too much snow lodge upon them in the winter, which is apt to break and displace the branches, whereby the Hedges will be rendered unsightly.

There are also some persons who have planted the Pyracantha, or evergreen Thorn, Juniper, Box, Cedar of Virginia, Bay, &c. as also the Halimus, or Sea Purslane, and the Furz, Rosemary, and several other plants for Hedges; but the five sorts first mentioned having very pliant branches, which will require to be supported, and the three last being often destroyed by severe frost, renders them unfit for this purpose; nor are there other sorts of evergreen plants in the English gardens, which are so well adapted for Hedges, as those before-mentioned.

The deciduous trees, which are usually planted to form Hedges in gardens, are the following sorts.

The Hornbeam is much esteemed for this purpose, especially in such places where they are not required to be very high, or not wanted to grow very fast; for this plant, while young, doth not make so great progress as many others; but as it is of slower growth the Hedges may be kept neat with less trouble than most other plants will require; and the branches naturally growing very close, they will make one of the closest Hedges of all the deciduous trees; but as the leaves of this tree continue upon the branches all the winter, and until the buds in the spring force them off, they have a bad appearance during the winter season.

[In Westphalia and other parts of Germany the Hornbeam is in great repute for Hedges. The German husbandman throws up a parapet of earth, with a ditch on each side, and plants his sets, railed from layers, in such a manner, as that every two plants intersect each other; there he scrapes off the bark, and binds them close together with straw. The plants consolidate, and form a living palisado, which being pruned annually with discretion, will in a few years make an impenetrable fence. It is not uncommon in Germany to see the sides of high roads thus guarded for many miles together. The Hornbeam is not delicate in point of soil; will put out strong lateral shoots within three inches of the ground; and is of quick growth *.]

The Beech is also a very proper tree for this purpose, having the same good qualities as the Hornbeam; but the leaves of this continue late in winter upon the branches, when they will have a bad appearance; besides, the litter which is occasioned by their leaves gradually falling most part of the winter, prevents the garden from being made clean a great while longer than if there are none of these trees planted.

The small-leaved English Elm, is also a proper tree for tall Hedges; if these are planted young, and kept closely clipped from their first setting out, the Hedges may be trained up to the height of thirty or forty feet, and be very close and thick the whole height. But when these trees are planted for this purpose, they should not be crowded so close together as they usually are by most people; by which method, when the trees have stood some years, if they have thriven well their stems will approach so near each other, as that few branches can be maintained below, whereby the bottom of the Hedge will be naked, therefore they should not be planted closer together than seven or eight feet, or if they are ten feet it will be still better. And although at this distance they will not form a close Hedge so soon as when the trees are planted closer together, yet they will in a few years recompense for that, by their growing much closer and better from the ground upward.

* Hunter's Evelyn.

The Dutch Elm was formerly in great esteem for Hedges, being quick of growth, and thriving in such soils as the English Elm would not grow; but the wretched appearance which these Hedges made, after they had been growing a few years, very justly occasioned their being almost universally rooted out of gardens, for a more abominable plant was never introduced into gardens than this.

The Lime-tree hath also been recommended for Hedges, and in some of the old gardens there were many planted with this tree, which, for a few years after planting, made a tolerable appearance, especially when they grow upon a moist soil; but after they had stood some years, they grew very thin at bottom, and by being sheered at the top, they were rendered very stubby and unsightly, their leaves growing very thinly upon the branches, and these frequently turning of a black disagreeable colour, and falling off very soon in the autumn, and sometimes in the summer in dry seasons, has brought these trees so much into disrepute, as that few persons make use of them at present for this purpose; nor should any of the very strong shooting trees be applied to this use; for the more they are cut, the stronger they will shoot, and of course will appear very unsightly; besides, the often cutting of these Hedges occasions great trouble and expense, and frequent litters in gardens.

The Alder is frequently planted for Hedges, and where the soil is moist, there is not any of the deciduous trees equal to it for this purpose; for the leaves are of a lively green, continuing fresh till late in the autumn; and when they decay, their litter is soon over, for they all drop in a short time.

There are, besides the trees before-mentioned, many of the flowering shrubs which have been planted to form Hedges; such as Roses, Honeysuckles, Sweet-briar, &c. but these make a bad appearance, being more difficult to train; and if they are cut to keep them within compass, their flowers, which are their greatest beauty, will be entirely destroyed. But as these are but of low growth, they are not proper to plant where the Hedges are to be of any height.

Although I have given these full directions for planting and ordering of these Hedges for the pleasure-garden, yet I am far from recommending them as ornamental or useful. But there are numbers of persons who may differ from me in their opinion, and therefore might think it a deficiency in my book, had I not given these instructions; to avoid their reproach, I have inserted as much as I think will be necessary for the obtaining these Hedges wherever they are desired, and at a less expense than the late method of planting them hath been generally attended with where it is not uncommon to see four times the number of trees planted in these Hedges as would have been necessary, or that can remain long close together with any beauty. But most people who plant are in too great a hurry to have their garden filled, and therefore frequently plant so close, as that in three or four years (if their trees thrive) three-fourths of them will require to be taken away again, to make room for those which are left to grow: and there are not wanting persons, who are ready enough to encourage this practice, since their own interest is thereby promoted.

The taste in gardening having been greatly altered of late years for the better, these clipped Hedges have been almost excluded; and it is to be hoped, that a little time will entirely banish them out of the English gardens, as it has already been done by the thorn Evergreens, which, a few years since, were esteemed the greatest beauties of gardens. The latter was introduced by the Dutch gardeners, and that of tall Hedges with treillage-work, was in imitation of the French gardens, in some of which, the expense of the iron treillage, to support the trees which compose their cabinets, pavillions, bowers, porticoes, and other pieces of rural architecture, amounted to a very great sum. I have been informed this work, in one garden, has cost above twenty thousand crowns; and this only to train up trees in the distorted shape of pilasters, niches, cornices, pediments, &c. when at the

ſame time, theſe can no longer retain the forms intended, than they are kept cloſely ſhorn into them; for no ſooner do the trees begin to make freſh ſhoots, but the whole frame is altered; and inſtead of carrying the fine finiſhed appearance of a regular piece of architecture, it is grown into a rude unpoliſhed form. This expenſive ſort of work never has made much progreſs in England, but that part of the French taſte, in ſurrounding all the ſeveral diviſions of gardens with tall clipped Hedges, making great alleys, forming the walks into ſtars, and the like ſtiff performances, once too much obtained in England: and the taller theſe clipped Hedges were, the more they were admired; though many times they ſhut out from the view the ſight of ſome of the nobleſt Oaks, and other timber trees, growing in the quarters, which are infinitely more pleaſing to a perſon of true taſte, than all the ridiculous forms it is poſſible for trees to be framed in by art. Beſides, when the expenſe of keeping theſe Hedges, together with the great litter they occaſion when clipped, is conſidered, theſe, added to many other reaſons which might be given, are ſufficient to exclude them out of gardens; where they can never be eſteemed neceſſary, but to ſhut out from the view the ſight of worſe objects.

[HEDWIGIA. (*So named from Joh. Hedwig, M. D. the famous author of* Hiſtoria Naturalis Muſcorum Frondoſorum, 1782 qu. and 1787 fol.)

SPECIES.

1. Hedwigia balſamifera.
Swartz prodr. 62.
Bois Cochon. *Nichols. hiſt. Dominq.* 169.

DESCRIPTION, *&c.*

This is a lofty tree, growing to the height of more than ſixty feet, with a trunk four or five feet in circumference: outer bark gray and even; inner red, thick and gummy: wood ſolid, and reddiſh. Leaves oval, ending in a lengthened point at top, without any indentations, thin, ſhining, waved, yelloviſh green, five or ſix inches long, and three inches wide, ranged in pairs along a midrib, terminated by an odd one. The flowers grow in a raceme at the extremities of the branchlets, and are white. The fruit is the ſize of a ſmall nut, divided into two or three parts, covered with a green coriaceous rind, and containing a white, fleſhy, ſweet pulp, having an aromatic ſmell: each diviſion has in it a flatted woody ſhell, incloſing a bitter oily kernel.—Native of St. Domingo.

The wood is uſed as timber for various purpoſes. An aromatic oil is drawn from the kernels, which is much eſteemed in diſorders of the breaſt. The red gum that iſſues from the bark has a ſtrong aromatic ſmell, and is much uſed in the cure of wounds. It is a notion that the wild ſwine firſt diſcovered this uſe of it, and hence it has the name of Bois Cochon[a].

SPECIES.

1. Hedycrea incana.
Gmel. ſyſt. 428.
Licania incana. *Aubl. guian.* 119. *t.* 45.

DESCRIPTION, *&c.*

This tree grows only to the height of three or four feet, with a trunk five or ſix inches in diameter. The bark is aſh-coloured, very thin, falling in large pieces, and renewing itſelf every year. The wood is hard, whitiſh, and when ſawed has the ſmell of rancid oil. The extremities of the branches and twigs have oval leaves, ending in a point, ſmooth and green on the upper ſurface, covered with a very white down underneath, and placed alternately; their petiole is ſhort, accompained at the baſe by two oppoſite ſtipules. The flowers grow in a ſpike at the ends of the branches and twigs: they are white, cloſe and ſeſſile. The fruit is the ſize of a large olive, white dotted on the outſide with red; the pulp is white, melting, and of a ſweetiſh taſte: the ſhell or nut is bony, and ſeparates with difficulty from the fibres in the pulp: the kernel is two-lobed.

Native of Guiana, where it is called *Caligni* by the natives, who are very fond of the fruit, which is ripe in october and november[c].

Oldenlandia stricta. *Lin. syst.* 162.
Leaves linear, stem decumbent, panicle racemed with the flowers directed one way, peduncles following the sun.

7. Hedyotis hispida.
Retz. obs. 4. *n.* 67.
Leaves linear-lanceolate, flowers in whorls.

8. Hedyotis rupestris.
Swartz prodr. 29.
H. americana. *Jacqu. amer.* 20.
Thymelæa, &c. *Sloan. jam.* 2. 94. *t.* 202. *f.* 1.
Leaves four-faced awl-shaped channelled, flowers sessile axillary, corollas villose with a crooked tube.

DESCRIPTIONS, *&c.*

1. Stems herbaceous, prostrate, a hand in length, smooth and even. Leaves opposite, on short petioles, spreading, somewhat fleshy. Flowers lateral. Fruit the size of Coriander.—Native of the East Indies. Koenig.

2. This has the appearance of Anagallis arvensis. Root annual. Stems little branched, a hand in length, smooth and even. Leaves like those of Anagallis, sharp at both ends, scarcely petioled, smooth and even. Peduncles lateral, solitary, capillary, upright, the length of the leaves. Capsule roundish, with a groove on each side, crowned with the four teeth of the calyx. Native of Tranquebar. *Koenig*[1].

3. This has the appearance of Phyllitis. Stem four-cornered. Leaves opposite, smooth, nerved, quite entire. Stipules ovate-rhombed, broad, short. Corymbs brachiate, or trifid. Calyx four-cleft. Filaments a little longer than the corolla: anthers oblong. Style bifid, blunt.—Native of Ceylon[2].

Retzius describes a species which he received from China, under this name of *H. fruticosa*, but as it differs in several respects from that which Linnæus describes as above in the Flora zeylanica, we cannot determine whether it be the same or not. His description runs thus—

Branches four-cornered, smooth, cloathed with rhomb-shaped stipules embracing the stalk, from the sinuses of which proceed leaves in pairs, lanceolate, quite entire, scarcely petioled. Flowers in a brachiate thyrse or panicle divided in the same manner as in the Galiums. Involucres none, but two subulate leaflets at the ramifications. Corolla tomentose within. Stamens in the middle of the tube: filaments very short: anthers linear. Style longer than the corolla; stigma capitate. Capsule ovate, four-toothed with the calyx. Seeds solitary, oblong.

4. Stems smooth, long. Branches long, jointed, alternate. Leaves subsessile, smooth, nerved, quite entire, opposite, pendulous. Stipules toothed, joining the peduncles. Flowers many, in whorls, on very short pedicels from each axil. It is accounted a specific in deafness.—Native of Ceylon[3].

5. Stem eight inches high, slender, procumbent. Leaves sessile, smooth, quite entire, opposite. Flowers axillary, in pairs, but often solitary: corolla white, subcampanulate. Stamens short. Stigma oblong, bifid. Capsule twin, crowned with the four tips of the calyx[4]; small, marked with two grooves, compressed at the tip; partition contrary to the cleft. Receptacle roundish, convex, excavated, the whole fastened to the middle of the partition on both sides. Seeds very numerous, small, smooth, brown[5].—Native of Ceylon and Cochinchina.

6. Perennial. Stems filiform, weak as in Stellaria graminea, a foot long. Leaves remotely opposite. Corolla blue; the segments before noon expanding very wide, in the evening two upright, and two bent back. Anthers upright, nearly equal, blue. Germ retuse: style the length of the corolla: stigma bifid, rolled back, villose. Capsule compressed, two-furrowed, two-valved, retuse; partition contrary; gaping

[1] Linn. suppl. [2] Linn. zeyl. [3] Ibid. [4] Loureiro. [5] Gærtner.

at

at the tip. Seeds very minute, numerous.—Native of the Eaſt Indies. *Koenig*[1]. It is repeated under the name of Oldenlandia ſtricta in ſyſt. veg. 162. 10. but it belongs rather to this genus[2].

7. Stems half a foot in length, decumbent, quadrangular, hiſpid, with a branch or two. Leaves petioled, acuminate, entire, hiſpid on both ſides. Petioles extremely hiſpid, united with the filiform torn ſtipules ſo as to form a ſhort ſheath. Pedicels ſcarcely obſervable. Calyx hiſpid. Segments both of that and the corolla ſharp. Stamens the length of the corolla. Style longer, club-ſhaped. Capſule half-two-celled, the partition diſappearing in the middle, and not reaching to the tip. Seeds many.—Brought from Canton by Wennerberg[3].

8. This is a ſhrub, ſeldom exceeding three feet in height. Branches diffuſed, often procumbent at the baſe, otherwiſe erect. Leaves linear, acuminate, quite entire, fleſhy, thick, ſhining, grooved at the back, convex on the ſides, oppoſite, numerous. The petioles are united on each ſide by a membrane embracing the branch, and blunt with a point. Flowers yellow, without ſcent, ſeſſile, axillary, ſolitary; the germ and part of the corolla is concealed within the ſinus of the leaf. There is a ſingle ſtipule on each ſide of the germ, of the ſame length and form with a calycine leaflet.—Native of Havanna, on rocks by the ſea coaſt[4]: alſo of Jamaica[5].

Indigofera linifolia. *Vahl ſymb.* 1. 55.
Leaves linear hoary, ſtem proſtrate, legumes globular.

4. Hedyſarum nummulariſolium. *Money-wort-leaved H.*
Lin. ſpec. 1051. *Reich.* 3. 501. *mant. zeyl. n.* 288. *Burm. ind.* 64.
H. rotundifolium. *Vahl ſymb.* 2. 81. & 3. 89.
Leaves wedge ſhaped.

5. Hedyſarum moniliferum. *Necklace Hedyſarum.*
Lin. ſyſt. 672. *Reich.* 3. 501. *mant.* 102. *Burm. ind. t.* 52. *f.* 3. *Petiv. gaz. t.* 26. *f.* 4. (Onobrychis).
Leaves orbiculate, legumes necklace-ſhaped globular-jointed.

6. Hedyſarum ſtyracifolium. *Storax-leaved Hedyſarum.*
Lin. ſpec. 1052. *Reich.* 3. 501.
Leaves cordate-orbiculate retuſe ſmooth on the upper ſurface, tomentoſe underneath.

7. Hedyſarum reniforme. *Kidney-leaved Hedyſarum.*
Lin. ſpec. 1051. *ſyſt.* 672. *Reich.* 3. 501. *Burm. ind. t.* 52. *f.* 1. *Laureiro fl. cochinch.* 447.
Leaves kidney-ſhaped, ſtem columnar.

8. Hedyſarum ſororium.
Lin. ſyſt. 672. *Reich.* 3. 501. *mant.* 270. *Pet. gaz. t.* 32. *f.* 1. (Lens).
Glycine monophyllos. *Burm. ind.* 161. *t.* 50. *f.* 2.
Leaves kidney ſhaped emarginate, ſtem three-ſided.

9. Hedyſarum veſpertilionis. *Bat-winged Hedyſarum.*
Lin. ſyſt. 672. *ſuppl.* 331. *Laureiro fl. Cochinch.* 447. *Jacqu. ic. vol.* 2. *collect.* 2. 329.
Leaves ſimple and ternate, middle leaflets two-lobed, lobes lanceolate divaricate, legumes plaited.

10. Hedyſarum gangeticum. *Oval-leaved Hedyſarum.*
Lin. ſpec. 1052. *ſyſt.* 672. *Reich.* 3. 502. *Burm. zeyl.* 113. *t.* 49. *f.* 2. *Pluk. alm. t.* 50. *f.* 3. (Onobrychis). *Laureiro fl. cochinch.* 448.
Phaſeolus monſanus. *Rumph. amb.* 6. 146. *t.* 66. *Burm. ind.* 164.
Leaves ovate acute ſtipuled.

11. Hedyſarum maculatum. *Spotted Hedyſarum.*
Lin. ſpec. 1051. *Reich.* 3. 502. *hort. cliff.* 449. *upſ.* 233. *fl. zeyl. n.* 290. *Dill. elth.* 170. *t.* 141. *f.* 168.
Leaves ovate obtuſe.

[12. Hedy

[1] Linn. ſuppl. [2] Swartz obſ. [3] Retzius. [4] Jacquin. [5] Sloane.

[12. Hedysarum latebrosum.
Lin. syst. 672. *Reich.* 3. 502. *mant.* 270. *Pet. gaz. t.* 30. *f.* 11.
Leaves ovate serrulate, legumes bid by a vaulted supine scarious bractle.

13. Hedysarum vaginale. *Sheathed Hedysarum.*
Lin. spec. 1052. *syst.* 673. *Reich.* 3. 503. *fl. zeyl. n.* 287. *Burm. zeyl.* 104. *t.* 49 *f.* 1. (Genista).
Leaves cordate-lanceolate, petioles simple, stipules sheathing.

[14. Hedysarum glumaceum.
Gmel. syst. 1121.
Hedysarum violaceum.
Vahl symb. 1. 54. *Forsk. descr.* 136.
Leaves simple lanceolate, stipules and calyxes scarious, legumes wrinkled.

15. Hedysarum imbricatum. *Imbricate-leaved Hedysarum.*
Lin. syst. 673. *suppl.* 336.
Leaves cordate, sessile stipuled, the upper ones imbricate flower-bearing.]

16. Hedysarum triquetrum. *Triangular-branched Hedys.*
Lin. spec. 1052. *syst.* 673. *Reich.* 3. 503. *fl. zeyl. n.* 286. *Loureiro fl. cochinch.* 418. *Burm. ind. t.* 52. *f.* 2. *Burm. zeyl.* 176. *t.* 82. (Onobrychis).
Phaseolatus montanus 7. *Rumph. amb.* 6. 146.
Leaves oblong, petioles winged, branches three-sided.

[17. Hedysarum strobiliferum. *Strobile bearing Hedys.*
Lin. spec. 1053. *Reich.* 3. 503. *fl. zeyl. n.* 289. *Burm. ind.* 165. (Onobrychis).
Bractles of the strobiles inflated cordate obtuse.

18. Hedysarum gramineum. *Grass-leaved Hedysarum.*
Retz. obs. 5. *n.* 70.
Leaves linear-lanceolate, stipules scarious, racemes naked, pedicels two-flowered, teeth of the calyx bearded.]

** *With conjugate leaves.*

19. Hedysarum diphyllum. *Two-leaved Hedysarum.*
Lin. spec. 1053. *syst.* 673. *Reich.* 3. 504. *fl. zeyl. n.* 291. *Swartz. obs.* 285. *Brown. jam.* 301. 10. *Sloan. jam.* 1. 183. *Raii suppl.* 458. *Pluk. alm. t.* 246. *f.* 6. & *t.* 102. *f.* 1. (Onobrychis). *Rheed. mal.* 9. 361. *t.* 82. (Nelam-mari). *Raii suppl.* 404.
β. H. bifolium, &c. *Burm. zeyl.* 114. *t.* 50. *f.* 1. *Loureiro fl. cochinch.* 449.
Leaves binate petioled, bractles in pairs ovate acute sessile.

*** *With ternate leaves.*

[20. Hedysarum adscendens.
Swartz prodr. 106.
Leaves roundish pubescent underneath, stem columnar, branches declined ascending hairy, racemes simple erect axillary.

21. Hedysarum pulchellum.
Lin. spec. 1053. *syst.* 673. *Reich.* 3. 504. *fl. zeyl. n.* 292. *Loureiro fl. cochinch.* 449. *Burm. ind.* 165. *Burm. zeyl.* 116. *t.* 52. *Pluk. amalth. t.* 433. *f.* 7. (Onobrychis).
Bractles in pairs conjugate orbiculate marked with lines.

22. Hedysarum elegans.
Loureiro fl. cochinch. 450.
Leaves obtuse tomentose on both sides, bractles conjugate ovate, legumes bowed.

23. Hedysarum spartium.
Lin. syst. 673. *Reich.* 3. 504. *mant.* 271. *Burm. ind.* 166. *t.* 51. *f.* 2.
Leaves ternate and simple somewhat tomentose, stem dichotomous, flowers in pairs, legumes jointed bifid.

24. Hedysarum lineatum.
Lin. spec. 1054. *syst.* 673. *Reich.* 3. 505. *Burm. ind. t.* 53. *f.* 1.
Leaves oblong marked with lines, racemes axillary, pendulous.

25. Hedysarum supinum.
Swartz prodr. 106. *Sloan. jam.* 2. 185. *t.* 218. *f.* 2.
Leaves ovate blunt soft hoary-villose underneath, stem branched procumbent, racemes simple erect terminating.]

26. Hedysarum canum.
Gmel. syst. 1124.
H. incanum. *Swartz prodr.* 107. *Plum. ic. t.* 149. *f.* 1.
H. canescens. *Mill. dict.*
Leaves ovate acuminate hoary underneath, stem columnar branched erect, racemes terminating erect, legumes declined rough with hairs.

[27. Hedysarum retroflexum.
Lin. syst. 673. *Reich.* 3. 505. *mant.* 103.
Racemes erect, legumes pendulous many-jointed.]

28. Hedysarum trigonum.
Swartz prodr. 107. *Brown. jam.* 301. 7.
H. intortum. *Mill. dict.*
Leaves ovate acute rough with hairs, stem climbing three sided, racemes very long axillary, legumes writhed bent in.

[29. Hedysarum umbellatum.
Lin spec. 1053. *syst.* 673. *Reich.* 3. 503. *fl. zeyl. n.* 293. *Burm. zeyl.* 115. *t.* 51.
Folium crocodili. *Rumph. amb.* 4. 112. *t.* 52.
Peduncles umbelliferous, stem shrubby.

30. Hedysarum biarticulatum.
Lin. spec. 1054 *Reich.* 3. 505. *fl. zeyl. n.* 296. *Burm. zeyl.* 114. *t.* 50. *f.* 2. *Raii suppl.* 457. 3. (Onobrychis).
Stem undershrubby, legumes two-jointed.

31. Hedysarum lappaceum.
Vahl symb. 1. 54. *Forsk. descr.* 136.
Leaves ternate obcordate, flowers axillary subsolitary, legumes two-jointed with hooked bristles.

32. Hedysarum heterocarpon.
Lin. spec. 1054. *Reich.* 3. 506. *fl. zeyl. n.* 294. *Burm. zeyl.* 117. *t.* 53. *f.* 1. *Tounb jap.* 287.
Flowers panicle-spiked, legumes jointed, the lowest one-seeded, stipules bristle-shaped.

33. Hedysarum viscidum.
Lin. spec. 1054. *Reich.* 3. 506. *fl. zeyl. n.* 295. *Burm. ind.* 167. *Burm. zeyl.* 187. *t.* 84. *f.* 1. (Phaseolus).
Legumes membranaceous even entire, stem and branches bispid.

34. Hedysarum scorpiurus.
Swartz prodr. 107. *Brown. jam.* 301. 9.
Leaves oblong hirsute underneath, stems procumbent three-cornered, racemes axillary, legumes roundish, upright.]

35. Hedysarum canadense. *Canadian Hedysarum.*
Lin. spec. 1054. *syst.* 673. *Reich.* 3. 506. *hort. upsf.* 232. *cliff.* 365. *Corn. canad.* 44. *t.* 45. *Mor. hist.* 2. 130. *s.* 2. *t.* 11. *f.* 9. (Onobrychis). *Park. theat.* 1090. *f.* 10.
Leaves simple and ternate, stem even, flowers racemed.

[36. Hedysarum gyrans. *Sensitive Hedysarum.*
Lin. syst. 675. *suppl.* 332. *Ait. hort. kew.* 3. 64. *Shaw. nat. misc. t.* 70. *Swartz obs.* 289. *Jacqu. ic. vol.* 2. *collect.* 3. 181.
Leaves oval-lanceolate obtuse, the lateral ones minute.

37. Hedysarum canescens. *Rough-leaved Hedysarum.*
Lin spec. 1054. *syst.* 674. *Reich.* 3. 506. *mant* 447. *hort. upf.* 232. *cliff.* 365. *Gron. virg.* 808. *Pluk. alm. t.* 308. *f.* 5.
Leaves scabrous underneath, stem bispid, flowers racemed conjugate.

38. Hedysarum repandum.
Vahl symb. 2. 82.
Leaves ternate repand-crenate, racemes terminating elongated.

39. Hedysarum adhærens.
Vahl symb. 2. 82.
Leaves ternate oblong, racemes axillary, legumes cylindric jointed villose.

40. Hedysarum marilandicum. *Maryland Hedysarum.*
Lin. spec. 1055. *Reich.* 3. 507. *Gron. virg.* 109. *Dill. elth.* 174. *t.* 144. *f.* 171. *Raii suppl.* 455. 3.
Leaves roundish, stem frutescent branched very much, legumes jointed even.]

41. Hedysarum tortuosum. *Twisted-podded Hedysarum.*
Swartz prodr. 107. *Ait. hort. kew.* 3. 64. *Sloan. jam.* 1. 184. *t.* 116. *f.* 2. *Brown. jam.* 301. 8.
Vahl symb. 2. 82.
H. purpureum. *Mill. dict.* n. 6.
Leaves oval-oblong obtuse smoothish, racemes erect axillary, legumes twisted compressed pubescent.

42. Hedysarum spirale. *Spiral podded Hedysarum.*
Swartz prodr. 107.
H. procumbens. *Mill. dict. n.* 10.
Leaves ovate obtuse smooth, stem very much branched, with diffused branches, racemes loose decurvate, legumes spirally twisted.

43. Hedysarum fruteſcens.
Lin. ſpec. 1055. *Reich.* 3. 507. *Jacqu. hort.* 3. *t.* 89. *Gron. virg.* 109.
Leaves ſubovate villoſe underneath, ſtem fruteſcent.

[44. Hedysarum axillare.
Swartz prodr. 107. *Brown. jam.* 301. 6.
Leaves rhombed roundiſh, ſtem creeping rooting, petioles upright, ſcapes axillary longer than the leaves.

45. Hedysarum viridiflorum. *Green-flowered Hedysarum.*
Lin. ſpec. 1055. *Reich.* 3. 507. *Gron. virg.* 109. *Pluk. alm. t.* 308. *f.* 5. (Onobrychis).
Leaves ſpearpiſh, ſtem upright, racemes very long upright.

46. Hedysarum hirtum.
Lin. ſpec. 1055. *ſyſt.* 674. *Reich.* 3. 508. *Gron. virg.* 2. 108. & edit. 173. (Trifolium).
Leaves oval, ſtem ſhrubby, ſpikes oblong, calyxes and fruits hirſute one-ſeeded.

47. Hedysarum junceum. *Slender-branched Hedysarum.*
Lin. ſyſt. 674. *Reich.* 3. 508. *dec.* 1. *t.* 4. *Amm. ruth.* 154. & 281. (Cytiſus).
Leaves lanceolate, legumes one jointed rhomb-ſhaped, pedunces ſubumbelled lateral.

48. Hedysarum violaceum. *Violet-flowered Hedysarum.*
Lin. ſpec. 1055. *Reich.* 3. 508. *Gron. virg.* 2. 108. & 1. 87.
Leaves ovate, flowers in pairs, legumes naked veined jointed rhomb ſhaped.

49. Hedysarum paniculatum. *Panicled Hedysarum.*
Lin. ſpec. 1056. *ſyſt.* 674. *Reich.* 3. 508. *Gron. virg.* 2. 108. *Pluk. maut. t.* 432. *f.* 6.
Leaves linear-lanceolate, flowers panicled, legumes rhomb-ſhaped.

50. Hedysarum nudiflorum. *Naked-flowered Hedysarum.*
Lin. ſpec. 1056. *ſyſt.* 674. *Reich.* 3. 509. *Gron. virg.* 2. 107. & edit. 1. 86.
Flowering ſtem naked, leafy ſtem angular.]

51. Hedysarum repens. *Creeping Hedysarum.*
Lin. ſpec. 1056. *ſyſt.* 674. *Reich.* 3. 509. *Gron. virg. ed.* 1. 86 &. 2. 108.
Leaves obcordate, ſtems procumbent, racemes lateral.

[52. Hedysarum hamatum. *Hook-podded Hedysarum.*
Lin. ſpec. 1056. *Reich.* 509. *amon.* 5. 403. *Brown. jam.* 298. 1. (Trifolium). *Sloan. jam.* 1. 187. *t.* 119. *f.* 2. (Anonis).
Styloſanthes procumbens. *Swartz prodr.* 108. *obſ.* 286.
β. Trifolium 2. *Brown. jam.* 299. *Sloan. jam.* 1. 186. *t.* 119. *f.* 1. *Burm. zeyl.* 226. *t.* 106. *f.* 2.
Styloſanthes viſcoſa. *Swartz prodr.* 108.
Leaves herved naked; ſpikes ſeſſile; legumes two-ſeeded, covered, having a hooked point.

53. Hedysarum triflorum.
Lin. ſpec. 1057. *Reich.* 3. 509. *fl. zeyl. n.* 297. *Burm. zeyl.* 219 *t.* 54. *f.* 2. *Loureiro fl. cochinch.* 450. *Swartz obſ.* 288.
β. *Burm. zeyl.* 118. *t.* 54. *f.* 1. *Retz. obſ.* 4. *n.* 95.
Leaves obcordate, ſtems procumbent, peduncles one flowered ſeldom three together.

54. Hedysarum barbatum. *Bearded Hedysarum.*
Lin. ſpec. 1055. *Reich.* 3. 510. *amon.* 5. 403. *Swartz obſ.* 287.
Racemes oblong ſomewhat branched, legumes bent in, calyxes hairy.

55. Hedysarum lagopodioides.
Lin. ſpec. 1057. *ſyſt.* 674. *Reich.* 3. 510. *Burm. ind.* 68. *t.* 53. *f.* 2. *Loureiro fl. cochinch.* 450.
Racemes oblong, legumes bent in, calyxes hirſute.

56. Hedysarum microphyllum.
Lin. ſyſt. 675. *Thunb. jap.* 284.
Leaves ovate villoſe, ſtem fruteſcent upright ſmooth, flowers terminating panicled.

57. Hedysarum racemoſum.
Lin. ſyſt. 675. *Thunb jap.* 285.
Leaves oblong ſtipuled ſmooth, ſtem fruteſcent, upright, racemes axillary upright very long, legumes ſmooth.

58. Hedysarum caudatum.
Lin. ſyſt. 675. *Thunb. jap.* 286.
Leaves oblong ſmooth, ſtem herbaceous, panicle terminating, legumes tomentoſe.

59. Hedysarum tomentoſum.
Lin. ſyſt. 675. *Thunb. jap.* 286.
Leaves tomentoſe underneath, ſtem angular tomentoſe, racemes axillary.

60. Hedysarum ſericeum.
Lin. ſyſt. 675. *Thunb. jap.* 287.
Leaves emarginate villoſe, ſtem fruteſcent upright, flowers axillary ſolitary.

61. Hedysarum virgatum.
Lin. ſyſt. 675. *Thunb. jap.* 288.
Leaves obtuſe with a point, ſtem angular, hairy, peduncles capillary three-flowered.

62. Hedysarum piloſum.
Lin. ſyſt. 675. *Thunb. jap.* 288.
Leaves ovate acuminate, ſtem decumbent rough with hairs, racemes axillary.

63. Hedysarum ſtriatum.
Lin. ſyſt. 675. *Thunb. jap.* 289.
Leaves oblong ſtipuled, ſtem herbaceous, flowers axillary ſolitary.

64. Hedysarum volubile. *Twining Hedysarum.*
Lin. ſpec. 1057. *Reich.* 3. 510. *hort. cliff.* 499. *Dill. elth.* 173. *t.* 143. *f.* 170.
H. ſcandens. *Mill. dict. n.* 13? See n. 89.
Leaves ovate-oblong, ſtem twining.

65. Hedysarum triangulare.
Retz. obſ. 3. *n.* 83.
Leaves ovate acute marked with lines, umbels axillary, branches three ſided flexuoſe.

**** *With pinnate leaves.*

66. Hedysarum argentatum. *Silvery Hedysarum.*
Lin. ſyſt. 675. *Reich.* 3. 511. *ſuppl.* 333.
H. grandiflorum. *Pallas itin.* 2. 743. *t.* y.
Aſtragalus grandiflorus. *Lin. ſpec.* 1071. *Gmel. ſib.* 4. 61. *n.* 78. *t.* 31. *Amm. ruth.* 168.
Leaflets ſilky underneath and ſhining, legumes jointed, ſtem leafleſs.

67. Hedysarum alpinum. *Alpine Hedysarum.*
Lin. ſpec. 1057. *ſyſt.* 676. *Reich.* 3. 511. *hort. upſ.* 232. *Gaertn. fruct.* 347. *Laureiro fl. cochinch.* 451. *Gmel. ſib.* 4. 26. *n.* 35. *t.* 10. *Amm. ruth.* 116. *n.* 152. 153.
Legumes jointed ſmooth pendulous, ſtem upright.

Lin. spec. 1060. *syst.* 677. *Reich.* 3. 515. *Pallas itin.* 1. 442. *Tournef. cor.* 29. *itin.* 2. *t.* 108. (Onobrychis).
Leaflets linear, legumes one-seeded even, stem shrubby, peduncles permanent-thorny.
84. Hedysarum incanum. *Hoary-leaved Hedysarum.*
Lin. syst. 677. *Tsunb. jap.* 289.
Leaves without stipules hoary underneath, stem erect, flowers in racemes drooping.
85. Hedysarum lineare. *Linear-leaved Hedysarum.*
Loureiro cochinch. 452.
Leaflets lanceolate-linear, spikes terminating, legumes straight smooth and even, stem diffused.]

86. Hedysarum ſericeum.
Mill. dict. n. 8.
Leaves ternate, leaflets ovate silky underneath, flowers in spikes axillary and terminating.
87. Hedysarum villoſum.
Mill. dict. n. 9.
Leaves ternate, stem diffused villose, flowers in terminating spikes, calyxes very villose.
88. Hedysarum glabrum.
Mill. dict. n. 12.
Leaves ternate, leaflets obcordate, stem panicled, legumes smooth, one-seeded.
89. Hedysarum ſcandens.
Mill. dict. n. 13.
Leaves ternate, leaflets obovate, stem twining, spike very long, bent back.
90. Hedysarum pedunculatum.
Mill. dict. n. 17.
Leaves ternate, the middle leaflet on a longer petiole, racemes axillary, upright very long.

DESCRIPTIONS, *&c.*

[The numerous species of this genus are mostly herbaceous, some few however (1. 6. 12. 16. 17. 18. 27. 29. 30. 40. 43. 46. 56. 57. 60. 73. 74. 75. 81. 83.) are shrubby, at least at bottom. The leaves are simple, ternate, or unequally pinnate; in one case only binate: hence the subordinate division of the genus into four parts. The stipules are distinct from the petiole. The petiolules of the ternate leaves are jointed into the petiole, and are frequently subſtipulated with a filiform stipule. The flowers are axillary with one or many-flowered peduncles; or they frequently terminate the stem in spikes or panicles. The bractes are sometimes large, varying in their construction; sometimes small or even almost evanescent. The legume varies in form, being in some species subcylindric with truncate joints; in others compressed, and frequently contracted at the joints either on one side or both. In some sorts the legume consists of one joint only, containing one seed. Some few have both simple and ternate leaves. Of the pinnate-leaved sorts, some have a crested legume, and are distinguished by the name of *Onobrychis*. The motion of the leaves in *H. gyrans* (36) is very remarkable [a].

Only one species (77) of this vast genus, namely the *Saint-foin* is a native of Great Britain: and only ten are natives of Europe. Far the greater part are perennial.]

1. Stems shrubby, about three feet high, branching out on every side. Leaves shaped like those of broad-leaved Knot-grass, very smooth, of a pale green colour, on short foot-stalks. Under these come out thorns, near an inch long, of a reddish brown colour. The flowers come out from the side of the branches in small clusters; they are purple in the middle, and reddish about the rims. Legumes sickle-shaped. [The leaves are scarcely stipulaceous; the spines are axillary, sometimes branched and floriferous: the legumes are coriaceous, subcylindric, and scarcely jointed [b].

Native of the Levant.

It is on this shrub that Manna (Trungebeen) is found in Mesopotamia [c]; and other Eastern countries.] It is chiefly gathered about Tauris, where the shrub grows plentifully. Sir George Wheeler found it growing in Tinos; Tournefort also found it in many plains of Armenia and Georgia, and made a distinct genus of it under the name of Alhagi, [from the Arabic *Agbul* or *Al-gul*.

It was cultivated in 1714, by the Duchess of Beaufort [d].

2. Stipules the length of the petioles. Legumes even, jointed, equal, upright. It varies with lanceolate and cordate-oblong leaves.

Native of India [e].

3. Annual. Stems wand-like, hoary. Leaves alternate, petioled, acute. Racemes very short, axillary. Legumes small, snow-white, with a permanent style, one-jointed.

[a] Jussieu. [b] Ibid. [c] Ruff. Alepp. [d] Hort. kew. [e] Linn. spec. and zeyl.

Native

Native of India. *Koenig*[a]: who ſent it under the name of *Indigofera linifolia*, which Vahl has adopted. The habit is different from that of the Hedyſarums, and the keel has a ſpur on each ſide as in the genus Indigofera.

4. Stems long, angular, diffuſed. Leaves alternate, ſimple, obverſely ovate or wedge-ſhaped, blunt with a ſhort point, ſmooth, on a very ſhort petiole. Stipules awl-ſhaped, longer than the petiole, patulous, very ſmall, clothing the ſtem. Spikes ſolitary from the axils, on a long peduncle. Flowers very ſmall. Legumes declined, creſcent-ſhaped, hiſpid on the back, containing one ſeed[b].

Native of India.—Introduced in 1777, by Daniel Charles Solander, LL.D. It is annual, and flowers here from July to September[b].

5. Stems a ſpan long, proſtrate. Stipules two-parted, ſtreaked, ſharp, ſcarioſe. Leaves ſmall, petioled, even, blunt. Heads of flowers axillary. Legumes ſubfaſciculed, peduncled, ſtraight, with globular joints often five in number, pubeſcent (the hairs when magnified appearing hooked), and rather large.

Native of India. Perennial[b].

6. Stem ſhrubby: that and the whole plant villoſe. Stipules lanceolate[c].—Native of China.

7. Stems annual, a foot and half high, branched, ſlender, ſmooth, procumbent. Leaves few, quite entire, ſmooth, ſcattered, ſolitary, the upper ones ternate, on long filiform petioles (the form of Aſarum leaves, but, ſmall, often retuſe, naked). Stipules minute. Flowers violet-coloured, in terminating ſpikes (or racemes) conſiſting of few flowers (two only; or a ſingle flower or two in the uppermoſt axils). Calyx hairy, converging. Banner of the corolla broad and very blunt. Legume ſlender, of ſix joints, bent back, ſmooth[d].

Native of India, and the ſuburbs of Canton in China.

8. Stem herbaceous, ſarmentoſe, ſmooth, a foot high. Leaves petioled, ſmooth, ſpotted. Petiole almoſt the length of the leaf. Stipules two, oval, ſmall, petioled, at the baſe of the petioles, ſo that the leaves might in ſtrictneſs be looked upon as ternate. Racemes lateral, axillary, capillary, longer than the leaf: pedicels in pairs. Legumes elliptic, ſmooth, ſharp, having two joints, the lower keel having a ſinus or two.—It reſembles the foregoing ſpecies, but is diſtinguiſhed by its three-ſided, ſarmentoſe ſtem, its ſpotted leaves, and its two-jointed legumes.

Native of India[e].

9. Annual. Stem four feet high, upright, very ſtraight, almoſt ſimple, round, but four-cornered at the top, furrowed, hiſpid with very fine hairs, frequently having one or two ſhort upright branchlets. Leaves ſomewhat creſcent-ſhaped four lines long, two inches broad, bent like a bow, retuſe, three-nerved, veins like a net, ſmooth, variegated yellow red and green: petioles long, ſtraight, ſlender, alternately by threes: ſtipules in pairs, ſharp, minute. Flowers in a ſimple, long, upright, terminating ſpike (or raceme). Calyx hairy, the three lower ſegments ſomewhat longer, all acuminate, and keeled at the back. Corolla white: banner broad-cordate, converging, a little longer than the calyx: wings bent in, ſhorter than the banner: keel of an intermediate length. Legume linear, ſmooth, ſlender; the joints ſomewhat lens ſhaped, connected by the dorſal thread, as they ripen plaited different ways, drawn within the inflated calyx, converging at the tip. Seeds ſomewhat kidney-ſhaped, flatted, ſhort, brown, ſmooth.—There are frequently ſmaller leaves at the top of the ſtem, unequally and obtuſely three-cornered, and ſometimes ternate.—In Cochinchina, but originally from Siam. It is cultivated for its beauty, and in a gentle breeze, the leaves as they move reſemble ſo many variegated butterflies[b].

Father Loureiro ſent this plant into Sweden and England in 1774.—According to the catalogue of the Royal garden at Kew, it was introduced in 1780, by Sir Joſeph Banks, Bart.; flowers in July and auguſt, and is biennial.]

10. This is an annual plant, about three feet high, having a ſlender ſtalk, inclining to be ſhrubby. Leaves on very ſhort foot-ſtalks. Some of the plants ſend out one or two ſlender branches from the main ſtalk, on the lower part of which are leaves of the ſame form with thoſe of the principal ſtalk, but ſmaller. On the upper part of the principal ſtalk and branches are flowers for near a foot in length, of a worn out purple colour, ſtanding ſingle at each joint. They are ſucceeded by jointed pods an inch and half long, containing three or four ſeeds.

[Allied to *H. ſyracifolium*, but larger[a]. Stem diffuſed, ſtipuled, round, hairy. Leaves oblong-ovate, or ovate-lanceolate, quite entire, hairy on both ſides, alternate. Flowers minute, in long, terminating ſpikes: banner and keel of the corolla yellow; wings violet-coloured. Legume bowed, at each joint emarginate on the convex ſide[b].

Native of India, and the ſuburbs of Canton.—Cultivated in 1768, by Mr. Miller: and flowering here in july and auguſt[c].

11. Perennial (annual, *Mill. & hort. kew.*), low, ſeſſile, but neither procumbent nor creeping. Stems ſeveral, from a hand to a long ſpan and a foot in height, either upright or reclining, round, ſlender, roughiſh, with ſlender hairs preſſed cloſe. Leaves alternate reſembling thoſe of the Caper and almoſt as large, thickiſh, ſmooth, green with paler ſpots, having a pair of ſharp ſtipules both at the baſe of the petioles and of the leaves themſelves. Flowers on the upper part of the ſtalk in pairs one above another, or ſometimes three together, on very ſlender peduncles, forming a long thin ſpike, in which each pair of flowers is placed in a contrary ſituation to the next. One ſegment of the calyx next the banner of the corolla is broader than the reſt, which are very ſlender. Corolla pale violet, (reddiſh yellow, *Miller*) the banner large in compariſon with the other petals; the wings are white at the baſe, and pale blue towards the end, but the keel is all over white. Legumes brown when ripe, roughiſh, compreſſed, in front divided by ſemicircular portions, but with an even line along the back, each portion when ripe ſeparates, and contains one kidney-ſhaped ſeed, ſlightly compreſſed[d].

Native of India.—Cultivated in Mr. Sherard's garden at Eltham in 1732. It flowers in july or auguſt.

12. Stem ſomewhat ſhrubby, naked; with few, wand-like, divaricate, round branches. Leaves alternate, petioled, remote, with ſcarcely apparent ſerratures ending in ſpines, ſmooth, the ſame ſize with thoſe of *Vaccinium Myrtillus*. Flowers axillary: peduncle very ſhort, two-flowered; with a leafy bracte, reſembling a dry wrinkled leaf, and defending the legume from the birds: this is inclining to rhomb-ſhape, is mucronate, and contains one ſeed.—Native of India[e].

13. This is allied to H. bupleurifolium. It is herbaceous and procumbent. The lower leaves are obverſely ovate, emarginate at the baſe; the upper ones more oblong, cordate-lanceolate, and more acute; all are ſmooth, veined, and the petioles are roundiſh. Stipules acuminate. Spikes towards the ends of the ſtems, long and narrow. Branches few. Legumes cylindric, ſmooth, jointed, ſtraight, dividing by joints, though they are ſcarcely apparent on the outſide, and there are no diviſions within.—It varies with lanceolate leaves[f].

Native of India. Annual.

14. Perennial. Stems woody, procumbent, wand-like, round, ſmooth, a foot high. Branches ſhorter than the ſtem. Leaves on ſhort petioles, ſpreading, acuminate, ſmooth, an inch long. Stipules lanceolate-ovate, the length of the petiole. Raceme terminating, when in flower two inches long, when in fruit elongated. Flowers uſually in pairs, ſeldom ſolitary. Calyx five-parted, ſcarioſe, ſtriated, hairy at the tip and on the edge. Legume an inch long; joints from four

[a] Linn. ſuppl. [b] Linn. syſt. [c] Hort. kew. [d] Linn. mant. [e] Linn. ſpec. [f] Loureiro and Linn. ſpec. [g] Linn. mant. and ſyſt. [h] Loureiro.

[a] Linn. ſyſt. [b] Loureiro. [c] Hort. kew. [d] Dillenius. [e] Linn. mant. [f] Linn. ſyſt. and syſt.

to ſix, compreſſed, roundiſh, wrinkled, terminated by the permanent ſtyle.

It differs from H. gramineum (18) in having the joints of the legumes broader, rounder, wrinkled; in other reſpects it reſembles that ſpecies much. It is allied to H. bupleurifolium (2) and vaginale (13); but their legumes are even and directed all the ſame way. The leaves in H. bupleurifolium, nummulariſolium (4), moniliferum (5) and vaginale, differ very much on the ſame plant, and are better diſtinguiſhed by the legumes [a]. It is very different from violaceum (48), though Vahl has inadvertently given it the ſame name.

15. Stems herbaceous, filiform, diffuſed, branched. Leaves quite entire, ſharp, even; the upper ones larger, but very like the others, and ſtipuled as they are. Stipules ſemicordate, ſcarioſe, patulous. Flowers among the upper leaves, ſolitary, ſeſſile, ſhorter, hid by the leaves. It differs from *H. ſtrobiliferum* in having ſtrobiles or ſcales of a form different from the leaves, in the peduncles and all other parts they agree.

Found by Thunberg at the Cape of Good Hope [b]. Doubtful whether it may not be the ſame with Glycine monophyllum.

16. Stems many, perennial, ſhrubby, procumbent, three feet long; with three-ſided branches. Leaves alternate, ſharp, with the ſides right-lined and almoſt parallel. Flowers purple, in ſpikes (or racemes) moſtly terminating. Banner roundiſh. Legume compreſſed, ſtraight, linear, jointed, (not ſerrate) hairy. In the Cochinchineſe plant, the leaves have not rounded margins, nor refracted petioles, as the plant of Ceylon has; but they have both lanceolate ſtipules, and the ſtem inclining to red at the end [c].

Native of India, China and Cochinchina.—In Chineſe Kaſong-ſo.

17. This is a tree, with oblong-ovate, alternate leaves, quite entire and petioled: ſtipules ſubulate; branches round. There are ſtrobiles from the axils of the leaves, as in the Hornbeam, on a ſimple flexuoſe peduncle, conſiſting of cordate, ſubſeſſile, obtuſe, numerous, imbricate bracteæ, like the involucre of the Commelina, large, and the rudiment of a flower within each of them. Theſe ſtrobiles diſtinguiſh this ſpecies from all the others, eſpecially from *H. pulchellum*. n. 21.

Native of India [a].

18. A ſhrub determinately branched. Stems round, ſtiff, jointed. Leaves two inches long, a line and half broad, acuminate, veined, petioles ſhort, brown. Stipules lanceolate, acuminate; there is a ſecond pair at the joint of the ſtem, which in the more adult branches is reſolved into fibres. Racemes ſtiff, elongated, leafleſs. Peduncles in pairs, one-flowered, diſtant. Calyx angular, ſcarioſe. Corolla ſmall, purple. Legumes convex-ancipital, ſmooth, mucronate, joints three to five, perhaps more.

Native of India: ſent by Koenig [a].

19 Annual. Stems herbaceous, procumbent, filiform, round, ſmooth. Leaves alternate: petioles ſtiff, horizontal, diſtant, round, ſmooth: leaflets on very ſhort petioles, oblong, ſharp, entire, nerved, ſmooth, pubeſcent underneath. Stipules oppoſite, on the ſide of the petioles at the baſe, obliquely ovate, acuminate. Peduncles axillary, terminating, longer than the leaves, upright, ſtiff, many-flowered. Flowers alternate, on very ſhort pedicels, between two oppoſite bracteæ, acuminate at both ends. Corolla yellow or purple. Calyx unequal; the two hinder cleſts converging, the two lateral ones ſmaller, rounded, the loweſt ſharp, longer. Banner of the corolla roundiſh, ſcarcely opening, veined, purpliſh; wings ſmaller than the banner; keel bowed in, acuminate. Legume a little longer than the bracteæ, upright: joints echinate, with one roundiſh, flatted ſeed in each [b].

Native of Jamaica, in the hot ſandy parts; South America; and the Eaſt Indies. Cultivated before 1733 by Mr. Miller, to whom Dr. Houſtoun ſent the ſeeds from Vera Cruz.

β. Root fuſiform, large. Stems herbaceous, round, ſlender, eight inches long, diffuſed. Leaves ovate, ſharp at the tip, ſmooth, ſmall; common petiole long; ſtipules in pairs, ſharp. Flowers yellow, axillary, ſolitary; calyx two-lipped, coloured, ciliate. Legume hiſpid, ſtraight; joints few, lens-ſhaped.—Found wild near Canton, and in Ceylon [c].

20. Native of Jamaica [a].

21. Stem ſhrubby, upright, three feet high, round, ſmooth; branches many, oblique, obtuſely angular. Stipules ovate, acuminate, cut, caducous. Leaflets broad-lanceolate, quite entire, ſmooth, on ſhort petioles, the middle one three times as large as the two others, and on a longer petiole. Spikes of flowers long, ſtraight, terminating. Bracteæ hiding each three flowers. Corolla yellow. Legume flat, ſtraight, acuminate, compoſed of two joints defended by the bracteæ. Native of India and China [c].

22. Stem ſomewhat ſhrubby, upright, three feet high, branched. Leaflets ovate, obliquely nerved. Spikes upright, moſtly terminating; flowers heaped, yellow, each with two hairy bracteæ, marked with lines. Legumes curved, hairy, erect, containing three ſeeds. At firſt ſight this ſeems to differ little from the foregoing ſpecies; it differs however in the leaves being blunt and hairy, the bracteæ ovate, the crooked form of the legume, and the greater number of flowers and ſeeds.—Native of China, near Canton [f].

23. This is a whitiſh plant, with ſhrubby ſtriated ſtems, very ſhort blunt ſtipules, and oblong leaves. Flowers ſcattered, ſubpedicelled, in pairs or ſolitary. Calyx very ſhort, five-toothed. Corolla yellow, with the claw the length of the calyx, and the border flat. Legumes orbicular-compreſſed, with red briſtles, and three joints.—Native of India [g].

24. Stem ſtraight. Racemes ſcarcely divided, the ſame length with the leaves, with the flowers hanging on looſe pedicels. Legumes rhomb-ſhaped, of one joint only, with one ſeed.—Native of Ceylon [b].

25. Root long, ſmall, woody. Stems a foot long, reddiſh, rough, round, woody. Leaves at unequal diſtances, on petioles half an inch in length; leaflets pale underneath, the middle one longeſt. Corolla purple. Legumes crooked, forming a ſemicircle, brown, the joints united by ſo ſmall an iſthmus, that when they adhere by their roughneſs to the clothes, they ſeparate, whence the Portugueze name of *Erva d'Amor*. Every joint contains one pale yellow ſeed.—It grows almoſt every where in the woods of Jamaica [i].]

26. Stem ſhrubby, about five feet high, dividing into ſeveral branches. The middle leaflet is much larger than the other two. The ſtalks are terminated by long ſpikes of ſmall purple flowers, which are ſucceeded by narrow pods, ſtraight on one ſide, but jointed on the other.

Native of Jamaica, whence Dr. Houſtoun ſent the ſeeds to Mr. Miller; and alſo of Hiſpaniola.

Cultivated by Mr. Miller before 1733.—Swartz has adopted the name *incanum*, which Thunberg had given to another ſpecies.

27. A ſhrub; very much reſembling *H. lineatum* (n. 24.), but the legumes have ſeveral joints. Leaflets ovate, tomentoſe underneath, ſilky. Racemes lateral and terminating, with pendulous, filiform peduncles. Legumes compreſſed, with one edge repand, and from four to ſeven joints.—Native of India [a].

28. It is a climber, and raiſes itſelf generally to the top of the talleſt trees in the wood. The ſtem is every where beſet with ſmall hooked briſtles, or rough hairs. The leaves are much like thoſe of the kidney-bean; and all the branches terminate in a large and beautiful flower-ſpike [i].

Native of Jamaica: whence the ſeeds were ſent by Dr. Houſtoun to Mr. Miller, who muſt therefore have cultivated it before 1733.

29. A ſhrub with woody branches, the lower ones round and brown, the upper ones angular and villoſe. Leaves petioled; leaflets ovate petioled, the middle ones twice the ſize of the others. Peduncles axillary,

[a] Vahl. [b] Linn. ſuppl. [c] Retzius. [d] Loureiro. [e] Swartz. [f] Loureiro. [g] Burm. ind. [h] Linn. mant. [i] Linn. ſpec. [k] Sloane. [l] Browne. [m] Linn. syſt.

ſolitary, ſhorter than the petioles. Flowers white, Legumes compreſſed, even, bowed back.—Native of India [a], Tanna, and New Caledonia.

30. Leaves like thoſe of Trefoil, with ovate-oblong, ſmooth leaflets, almoſt equal. Flowers in ſpikes. Legumes villoſe, uſually compoſed of two round joints. Native of India [b], and China.

31. Stems ſuffruticoſe, proſtrate, pubeſcent, round, the thickneſs of a pigeon's quill, very much branched. Leaves on very ſhort petioles: leaflets ſeſſile, thick, villoſe, ſmall, having a reflex point at the end; the lateral ones ſmaller. Stipules minute, awl-ſhaped. Flowers on ſhort peduncles, ſolitary, ſeldom two together. On each peduncle an awl-ſhaped bracte. Calyx villoſe, with awl-ſhaped ſegments. Banner and keel double the length of the calyx: wings linear, of the ſame length with the calyx. Germ villoſe. Legume half an inch long; joints orbicular, compreſſed, villoſe, with ſtiff briſtles, reflex and hooked at the end [c].

32. Stems round, hardiſh. Stipules acuminate, ending in a briſtle. Leaves petioled: leaflets ovate-oblongiſh, blunt, on petioles, the middle one more produced. Spikes of flowers narrow. Lower legumes of one joint only, the reſt of more, waved on one ſide. There is a variety which is more procumbent, with blunter leaflets: the loweſt legumes of this are not always one-jointed [d].

Stem herbaceous, ſtreaked, ſmooth, drooping, two feet high and more. Leaves ſmooth: leaflets oblong, blunt with a point, entire, nerved, pale underneath, ſpreading very much, an inch in length, the middle one larger and on a longer petiole. Flowers in racemes, fleſh-coloured. Racemes axillary, frequent, ſpreading and drooping [e].

Native of Ceylon, China, Japan, and the Society iſles.

33. Stem ſhrubby. Leaves on longiſh petioles: leaflets broad, from round inclined to rhomb-ſhape, the middle one twice as large as the others. The upper branches are hiſpid with ſpreading, viſcid hairs. Legumes oval-oblong, membranaceous, blunt at both ends, neither of the ſutures ſinuate, but both entire [f]. Native of India.

34. It grows in tufts, and ſeldom riſes above ſixteen or ſeventeen inches from the root.—Native of Jamaica and Hiſpaniola [g].

35. This is an upright plant, and moſtly ſmooth. Stem ſtreaked and angular. Leaflets lanceolate. Stipules awl-ſhaped [h]. Perennial.—Native of Virginia and Canada. Flowering in july and auguſt. Cultivated in 1640, according to Parkinſon [i].

36. Root branching, perennial (biennial, *hort. kew.* annual, *Swartz. obſ.*). Stem ſhrubby, three feet high, wand-like, upright, very ſmooth, round, without knots. Leaves alternate, petioled, hanging down or ſpreading, often vertical, ſometimes ſimple but uſually ternate, eſpecially in adult plants: the middle leaflet lanceolate, long, flat, quite entire, very ſmooth, veined; the ſide ones very ſmall, and ſeeming rather to be appendicles than leaflets; they are on ſhort petioles, which are remarkable for a motion peculiar to them. The common petiole is ſpreading, half round, ſhorter than the leaf, and villoſe. Stipules lateral, upright, awl-ſhaped, ferruginous, deciduous [k].

Racemes terminating and axillary, rather ſimple, many-flowered, long, leafleſs, pubeſcent. Flowers nodding. Bractes ſolitary, membranaceous, cordate under the flowers, deciduous. Calyx erect two-lipped; upper lip trifid; lower with two ſmaller contiguous teeth. Banner of the corolla largiſh, roundiſh, entire, brown with duſky ſtreaks; wings connected with the keel by their upper edge, brown; keel longer than the wings, bifid at the baſe and tip, compreſſed, ferruginous. Legume on a ſhort pedicel, compreſſed, channelled at the back, crenate in front, gaping, containing five or ſix, kidney-form, oblong ſeeds [l].

The leaves are of a bright green, with the middle part of a more glaucous appearance than the reſt. Flowers pale red, ſlightly tinged with blueiſh, and ſometimes yellowiſh [m].

The ſingular motion with which the lateral leaflets or appendicles of this plant are endued is thus deſcribed in Linneus's ſupplement.

"This is a wonderful plant on account of its voluntary motion, which is not occaſioned by any touch, irritation, or movement in the air, as in Mimoſa, Oxalis and Dionæa; nor is it ſo evaneſcent as in Amorpha. No ſooner had the plants raiſed from ſeed acquired their ternate leaves, than they began to be in motion this way and that; this movement did not ceaſe during the whole courſe of their vegetation, nor were they obſervant of any time, order or direction; one leaflet frequently revolved, whilſt the other on the ſame petiole was quieſcent; ſometimes a few leaflets only were in motion, then almoſt all of them would be in movement at once: the whole plant was very ſeldom agitated, and that only during the firſt year. It continued to move in the ſtove during the ſecond year of its growth, and was not at reſt even in winter."

Swartz obſerves that the motion is irregular, and that it ſometimes ceaſes entirely; that in a very hot day it is immoveable, being agitated only in the evening, and that ſlowly.

In our climate the leaves in general only make a faint and feeble attempt towards the middle of the day at exerting their extraordinary faculty [n].

We are at a loſs to account for this motion, which does not depend upon any external cauſe that we can trace, and which we are not able to excite by any art that we poſſeſs. It is not the action of the ſun's rays, for this plant is fond of ſhade, and the leaves revolve well on rainy days, and during the night: expoſed to too much wind or ſun, it is quiet. Perhaps, ſays Linneus, there may be ſome part in vegetables, as in animals, where the cauſe of motion reſides [o].

It is a native of Bengal near the Ganges: and is called there *Burum Chadali* or *Surran Chandali*. It grows luxuriantly, and flowers, in the gardens at Jamaica. It was introduced here in 1775, by Patrick Ruſſel, M.D. and flowers in july and auguſt [p]. Forſter ſent the ſeeds to Linneus in 1778.

37. This reſembles *H. canadenſe* very much. It is an upright, hairy plant. The leaflets are ovate. Stipules awl-ſhaped, ſubcordate. Flowers white.

Native of Virginia [q].

38. Stem woody, round, purpliſh, pubeſcent at top. Leaflets on a ſhort petiole ovate, unequal; the lateral ones ſmaller, oblique on one ſide; the end one ſomewhat rhomb-ſhaped, an inch and half long, almoſt double the ſize of the others, all repand-crenate from the middle upwards, blunt, mucronate, paler underneath, villoſe on the veins. Petioles two inches long, pubeſcent, jointed and thicker at the baſe, with two briſtle-ſhaped ſcales between the leaflets. Stipules lanceolate, ciliate. Peduncle terminating, erect, half a foot long. Flowers very remote, purple, before they open drooping. Pedicels two or three at each joint, capillary, pubeſcent, an inch long, ſomewhat clammy. Calyx pubeſcent. Wings lanceolate, ſhorter than the keel. Legume linear.

Native of Arabia.

39. Stems weak, ſimple, three-ſided, ſomewhat hairy. Leaflets petioled, an inch long, the ſide ones ſmaller, having long hairs thinly ſcattered over both ſurfaces, and preſſed cloſe to them. Petioles an inch and half long, hairy. Stipules ſemiovate, nerved, ciliate, acuminate. Racemes two or three inches long. Pedicels alternate, remote. Bractes lanceolate, nerved, ending in a dagger-point, that is ſcarcely pungent. Legumes an inch long, erect, a little incurved; joints oblong, covered with hooked hairs. It may be doubted whether it be different from H. trigonum (28).

Native of the Weſt Indies [r].

40. Root perennial. Stems ſeveral, as thick as a ſmall quill, eighteen inches or two feet and upwards

in

in height, round, ſmooth, ſtiff, upright, with alternate leaves from top to bottom, like thoſe of *Trifolium bituminoſum*, but blunter, pale underneath and covered with ſoft hairs, eſpecially on the upper and young leaves, which are hoary with a ſilky down: the middle leaflet is larger and broader than the others, inclining to rhomb-ſhaped: petioles ſlender and ſhort, with a pair of ſtipules at their baſe and on the middle pedicel. Flower-ſtems ſquariſh and roughiſh, with ſmall flowers diſtant from each other in two long rows on ſhort ſlender peduncles. Corolla purple fading to blue: banner broadiſh, firſt concave then ſpreading, having a greeniſh ſpot at the baſe; wings applied to the keel, of a purple colour; keel compreſſed, whitiſh towards the baſe. Calyx divided into four ſhort ſegments. Legumes ſhort, compreſſed, not rough, but ſlightly hirſute with ſome oblique veins.

Native of Virginia, Carolina, Maryland. Cultivated in Dr. Sherard's garden at Eltham in Kent, in 1725; it flowered there the beginning of october, 1729[f].

41. It grows erect, and riſes generally to the height of two feet and a half or more. The leaves are moderately large, and the ſtipules are roundiſh and broad. Flowers in ſpikes thinly placed, on pedicels half an inch long; corolla of a pale purple colour. Legumes ſlender, roughly variouſly turned and diſtorted.

Frequent in the more remote hills, and inland parts of Jamaica [g], and Santa Cruz, alſo in Vera Cruz; whence it was ſent by Dr. Houſtoun. It flowers here in july and auguſt; and was cultivated by Mr. Miller in 1731 [h].

Vahl, who deſcribes this, has another ſpecies ſent by Pflug from the ſame iſland of Santa Cruz, which he calls H. molle. It reſembles the tortuoſum, but has a ſtronger ſtem, with larger leaves, ſoftly villoſe underneath, the younger ones on both ſides, not at all ſpotted: pedicels aggregate, often four or five: the legumes are double the ſize, with the laſt joint very large in compariſon with the reſt [i].]

42. Stems woody, trailing, a foot and half long, ſending out ſeveral branches on each ſide. Leaflets ſmall, pale green. Flowers ſmall, of a pale purpliſh colour. Legumes narrow; each joint four-cornered, containing a ſingle, ſmall, compreſſed ſeed. Annual. Native of Jamaica.

43. Root perennial. Stems two or three ſhrubby, hairy, near two feet high, branching on every ſide near the top. Leaves ovate-lanceolate, hairy underneath, on ſhort foot-ſtalks. Flowers at the ends of the branches in ſhort ſpikes, purpliſh-yellow and ſmall. It was ſent by Dr. Dale from South Carolina.

[Jacquin thus deſcribes his H. frutеſcens, which is probably a different plant. Stems ſeveral, round, ſhrubby, perennial, wand-like, ſeveral feet in length, branched; the younger ones villoſe, procumbent or ſupporting themſelves. Leaves alternate, on villoſe petioles; leaflets ſuboval, blunt, quite entire, villoſe underneath, almoſt ſmooth above; at the bottom of the ſtem often rounded. Stipules to the leaf lanceolate-acuminate; to the leaflets briſtle-ſhaped and caducous. Racemes terminating, looſe, half a foot long and more. Pedicels in pairs, ſpreading, each one-flowered. Flowers purple, ſmall, without ſcent. Calyx villoſe: upper lip ſemibifid, lower trifid, the ſegments acuminate, erect. Banner very widely ovate; wings and keel oblong. Legume an inch long, very much compreſſed, brown, rough, five-jointed.]

44. This runs many feet from the main roots, commonly caſting a few fibres from all the joints that touch the ground, which greatly forwards its luxuriant growth. The leaves are marked with ſome prominent veins on the under ſide, and are ſeldom leſs than an inch and half in length.—Common in the ſhady hills of Jamaica [k], and Domingo.

45. Native of North America. Introduced in 1787, by Thomas Walter, Eſq. Perennial [l].

46. Spikes oblong. Legumes of one joint, ovate, acute. In gardens, the firſt year it bears mutilated flowers, and yet is fruitful. The ſecond year the corollas are white.—Native of Virginia [m].

47. *Root* perennial. *Stem* herbaceous, two feet high, ruſhy, wand-like, round, ſomewhat furrowed, ſmooth, ſomewhat pubeſcent towards the end; branches of the ſame length and ſtructure with the ſtem, alternate, few. *Leaves* alternate, petioled, reflex: leaflets petioled, ſmooth, quite entire, bluntiſh with a point, the two lower on ſhorter petioles; theſe are the length of the leaflets, ſemicylindric and ſmooth. *Stipules* permanent, ſubulate, at firſt erect then ſpreading, very ſhort, purpliſh. *Racemes* axillary, few-flowered (at moſt eight), leafleſs, a little longer than the leaves, peduncled. *Peduncles* twice as long as the petioles, filiform, ſmooth. *Flowers* in pairs, erect, pedicelled. *Bractes* ſmall, ovate, ſcarcely viſible. *Calyx* ſegments ſharp, the three upper approximating, the two lower divaricating. *Corolla* white; banner broad, roundiſh, ſcarcely emarginate with blood-red ſtreaks at the baſe; wings ovate, rounded at the tip; keel bifid from the tip to the middle, the lobes rounded. *Legume* ovate, compreſſed, mucronate, one-ſeeded, ſcarcely larger than the compreſſed calyx. *Seed* yelloviſh, oblong, the ſize of the legume.—When the plant firſt grows up in the ſpring, the ſtems are more pubeſcent, in greater number, more ſimple, purple and almoſt blood-red; in the ſummer they are green; the lower leaves are ſimple not ternate, and purpliſh.

Native of India [n].—Linnæus received the ſeeds from David van Royen in 1761. It was introduced here in 1776, by Monſ. Thouin: and flowers in july and auguſt [o].

48. Flowers violet-coloured, in pairs, uſually connected by their proper pedicels, in ſome glomerate from the axils of the leaves, in others fixed here and there on filiform peduncles. Legumes three times as long as the calyx, ſharp, ſmooth, netted, containing one ſeed [p].

Native of North America.—Introduced in 1787, by Thomas Walter, Eſq [q].

49. Flowers purple [r].—Native of Virginia. Introduced in 1781, by Monſ. Thouin [s].

50. Flowers purple [t].—Native of Virginia.

51. Clayton deſcribes the American plant to have procumbent woody ſtems; ſmooth leaves; flowers variegated red and white, or ſometimes white only, on long upright axillary peduncles, diſpoſed in a ſmall ſpike; legumes ſhort, acuminate, ſmooth, compreſſed, containing one very ſmall ovate ſeed [u].—Dillenius thus deſcribes the Ceyloneſe plant, which is probably different from the Virginian.

Annual. Stems many, ſlender, from a long ſpan to a foot and a foot and half in length, round, red, hairy. Leaves at firſt ſingle, afterwards moſtly ternate, roundiſh, like thoſe of Strawberry-Trefoil, ſometimes obcordate, ſometimes not, thickiſh, frequent, ſmooth above, ſomewhat hoary underneath, on ſlender hairy petioles; at their baſe a pair of broadiſh ſtipules, and another pair at the baſe of the leaves, which are ſlender. The flowers come out towards the end of the ſtalks, ſometimes ſingle, ſometimes two, three or four together, on extremely ſlender pedicels; they are ſmall and purpliſh; the calyx is divided into five narrow, hairy ſegments. Legumes ſhort, brown, with ſlender tranſverſe wrinkles, rather ſmooth however than rough, with ſome fine hairs about the edge. Seeds ſmooth, greeniſh aſh-colour with black dots [v].

Native both of the Eaſt and Weſt Indies.—Dillenius ſays, that it grew in the Eltham garden from Ceylon ſeeds, ſent by Commelin.—Miller received the ſeeds by Dr. Houſtoun from the Havannah. They cultivated it therefore about the ſame time. It flowers in july, and ſometimes perfects ſeeds in auguſt or ſeptember.

52. Root long, deep. Stems many, round, hairy, from ſeven or eight inches to a foot in length, creeping, branched. Leaflets ſmall, ſmooth, ſhining, ciliate, having many beautiful white nerves on the under ſur-

[a] Dillenius. [b] Browne and Sloane. [c] Hort. kew. [d] Symb. 2. 85. [e] Browne. [f] Hort. kew. [g] Linn. ſpec. and ſyſt. [h] Linn. dec. [i] Hort. kew. [k] Linn. ſpec. [l] Hort. kew. [m] Linn. ſyſt. [n] Hort. cliff. 172. [o] Hort. kew. [p] Linn. ſyſt. [q] Gron. fl. virg.

face.

face. The flowers come out towards the top; they are of an orange colour, with a little purple in the middle. Legume ſmall, rough, ſeldom exceeding two lines in length, never containing above one ſeed, which is reddiſh.—Native of Jamaica[r], Hiſpaniola, and Ceylon.

Swartz makes this ſpecies to be of a genus totally diſtinct, and even very different from all the others of this claſs; becauſe it has a corolliferous calyx, and an inferior germ, in the ſame manner almoſt as *Oenothera*.

β. Stems from one to two feet in length, ſhrubby, gray, branched into many twigs, which are green and hoary. Leaflets purple on the edge, having purple ſpots on their backs, and a down of the ſame colour; petioles half an inch long. Flowers on the tops of the twigs, yellow, ſeveral opening ſucceſſively. Legume very ſhort, thin, ſhaped like a ſcymitar, having ſeveral lines or nerves on it, containing one ſeed, which is ſhining, brown, with a point on one ſide and defect on the other[s].

Native of Jamaica, and Ceylon, for this ſeems to be Burman's plant.—Swartz makes this a diſtinct ſpecies, under the name of *Stylosanthes viſcoſa*.

53. Roots ſimple, long. Stems filiform, crowded, when magnified appearing three-cornered, ſubdivided, pubeſcent. Leaves alternate. Petioles ſhort. Stipules oppoſite, acuminate, membranaceous, at the baſe of the petioles. Leaflets roundiſh, obcordate or ſlightly emarginate, ſmall, nerved, netted, ſmooth above, glaucous underneath. Peduncles oppoſite to the petioles, ſimple, ſolitary, two or at moſt three together, the length of the petioles; filiform, one-flowered. Flowers minute, ſcarlet. Calyx two-lipped; the three hinder ſegments linear, contiguous, ſharper, the two in front diſtant, lanceolate. Banner of the corolla roundiſh-cordate, ſpreading, reflex, pale; wings and keel ſhorter than the banner, approximating, ſcarlet. Legume ſmall, peduncled, crenate in front, containing three or four ſeeds, which are roundiſh and minute.—It wakes at ten o'clock in the morning, and ſleeps at four in the afternoon[t].

Stem annual, round, ſhort in tufts. Leaves obcordate, ſmooth, ſmall, petioled. Flowers white, on one-flowered, heaped, axillary peduncles. Legumes bowed, containing ſeveral ſeeds[u].

Native of both Indies and China.—The Eaſtern cannot be diſtinguiſhed from the Weſt-Indian plant[v]. And yet the deſcriptions do not perfectly agree.

β. Stems ſcarcely half a foot long, hiſpid. Leaflets obcordate, both they and the petioles hiſpid and naked. Stipules ovate, ſharp, ſtreaked. Peduncles the length of the leaf, axillary, ſolitary, one-flowered, oppoſite to the leaves. Flowers ſmall. Calyxes hiſpid. Legumes ſometimes of one joint, ſometimes of ſeveral, with one edge entire[w].

Native of Ceylon and China.

54. Stem procumbent, from three to five inches in length, branched, round, ſomewhat ſhrubby at the baſe, even: branches procumbent, almoſt ſimple, ſhort, round, pubeſcent. Leaves petioled. Petioles alternate, thicker at the baſe, filiform, ſhort, round a little flatted, ſmooth. Leaflets obovate, petioled, the middle one double the ſize of the two others, entire, ſomewhat glaucous above, hoary on the back. At the tips of the leaves are very ſhort little briſtles. Stipules oppoſite, at the baſe of the petioles, ſeſſile, lanceolate, ſharp. Flowers terminating, in a ſort of ſpike, comoſe. Peduncles long, two, approximating, filiform; the flowers nodding, pale blue. Calyx ſubbilabiate; the two upper ſegments approximating, the tips linear, hirſute; the three lower ones diſtant, parted to the baſe, lanceolate, hirſute, whence there is a broad hirſute ſpike. Banner of the corolla ſpreading at top, roundiſh; wings lanceolate, blunt: keel ovate, bowed in, ſpreading. Legume lanceolate, bent variouſly, bowed in: joints roundiſh, ſmooth. Seeds roundiſh, compreſſed.—Native of Jamaica, in the dry ſandy parts[x].

55. Stem underſhrubby, upright, two feet high, round, hiſpid: with diffuſed branches. Leaves ternate, ſometimes quinate; leaflets ovate-lanceolate, ſmooth, (blunt, naked, terminating in a very ſmall briſtle, *Lin. ſpec.*). Stipules lanceolate, minute. Flowers dark purple, in oblong, denſe, very hirſute, terminating ſpikes. Bractes roundiſh, acuminate, two-flowered, deciduous. Peduncles one-flowered, long, bent in, hirſute. (Calyx very ſhort, the ſegments ending in three hirſute briſtles, *Lin.*), converging, and concealing the corolla with many long hairs. (Corolla ſmall, *Lin.*) Legume linear, coloured (even, having three or four joints, *Lin. fil.*) which are drawn back and plaited. Seeds flatted, brown, even, ſmall[y].

Native of China, and New Caledonia.—Loureiro remarks that Burman's figure does not agree with his obſervation, in the number and form of the leaves.

56. Stem filiform, purple: branches alternate, frequent, upright, like the ſtem, ſubdivided: twigs capillary, ſhort, reflex, almoſt covered, as well as the branches, with ſtipules. Leaves petioled: leaflets acute, entire, nerved, the upper ſurface ſmooth, the lower villoſe and pale: the middle leaflet on a long petiole, the ſide ones on ſhorter. Petioles capillary, purple, ſmooth. Stipules ſeſſile, ovate, awl-ſhaped, membranaceous, frequent. Flowers on capillary pedicels, alternate, or ſubdichotomous, flexuoſe; purple, hiſpid. Calyx hirſute. Corolla purple. Legumes of three joints, villoſe-ſcabrous.—It differs from *H. ſtipulaceum* in its fruteſcent, upright ſtem; in its ovate, acute, villoſe leaves; in having the flowers growing in a kind of raceme:—from *H. marilandicum*, in its ſcabrous legumes: from *H. fruteſcens*, in its ſmooth ſtem: and from *H. repens* in having the racemes terminating.—It flowers in auguſt and ſeptember.—This and the following ſpecies are natives of Japan.

57. Stem ſmooth; branches alternate, angular, ſmooth, purple, upright. Leaves alternate, petioled: leaflets petioled, the middle one on the longeſt, ovate-oblong, acute, entire, ſpreading, hoary underneath, the middle one twice as large as the two others: petiole filiform, ſmooth, an inch in length: ſtipules two, briſtle-ſhaped, half a line long, between the two ſide leaflets, and below the odd one. Racemes a hand or more in length, from upright-ſpreading, capillary, ſmooth, often ſeveral: pedicels ſolitary or in pairs, one-flowered, very ſhort, capillary. Calyx and corolla ſmooth. Legumes compreſſed, acuminate, even. It reſembles *H. viridiflorum*; but differs in having axillary, not terminating racemes; legumes ſharp and ſmooth, not blunt and rough; and briſtle-ſhaped ſtipules on the upper part of the common petiole.

58. Stem upright, ſmooth, ſimple, a foot or more in height. Leaves petioled, upright: leaflets acute, entire, nerved, the middle one larger and on a longer petiole than the two ſide ones: petioles ſemicylindric; channelled: ſtipules two, at the baſe of the petiole, between the ſide leaves, and below the odd one; they are briſtle-ſhaped. Calyx hirſute. Corolla purple. Legume almoſt linear, with a ferruginous down on it.—It reſembles *H. gangeticum*, but is diſtinguiſhed from it by the ternate leaves in this.

59. The whole plant, except the upper ſurface of the leaves, is tomentoſe. Stem herbaceous, angular, flexuoſe, upright, a foot or more in height. Leaves petioled: leaflets ovate-oblong, blunt with a point, entire, edged, marked with lines and nerves; the ſide ones on very ſhort petioles, only half the ſize of the middle one, which is an inch in length: petiole furrowed, upright, an inch long. Stipules two, at the baſe of the petiole, broad at the baſe, briſtle-ſhaped.

60. Stem many-ſtreaked, upright, villoſe at the corners, two feet high and more: branches alternate, very frequent, wand-like, upright, ſubdivided a little, reſembling the ſtem. Leaves very frequent, on ſhort petioles, ſilky-tomentoſe on both ſides: leaflets oblong, tapering at bottom, retuſe with a point, ſubſeſſile, upright, half an inch long, the middle one longeſt. Stipules briſtle-ſhaped. Flowers on very ſhort peduncles. Calyxes ſilky-tomentoſe.—It differs from *H. ſtriatum*, in having the ſtipules briſtle-ſhaped, not preſſed

[r] Sloane and Browne. [s] Sloane. [t] Swartz.
[u] Loureiro. [v] Swartz. [w] Retzius. [x] Swartz.

[y] Loureiro.

cloſe;

close; the leaves longer, retuse, silky, not streaked; the stem upright and stiff, frutescent. It flowers in september and october.

61. Stem herbaceous, with hairy angles, upright, purplish: branches alternate, filiform, angular, hairy, from erect-spreading, wand-like. Leaves on very short petioles: leaflets also on very short petioles, ovate, entire with the edge reflex, marked with lines; the upper surface green and smooth, the lower pale and hairy; the middle one largest. Flowers axillary; peduncles hairy, three-flowered at the tip, from spreading reflex, an inch long.

62. Stem herbaceous, filiform, very hairy: branches few, alternate, short, resembling the stem. Leaves petioled, villose on both sides: leaflets on short petioles, blunt with a bristle-shaped point, spreading; the odd one a little larger and on a longer petiole than the two sides ones. Each raceme has about four flowers. Peduncle capillary, scarcely the length of the petiole. Corolla purple.—It flowers in september.

63. Stem angular, hairy, rather upright though weak, a foot high and upwards: branches alternate, wand-like, frequent, spreading, simple. Leaves on short petioles: leaflets blunt, somewhat retuse, acuminate, with a small bristle, entire, with parallel streaks, smooth except the dorsal rib, which is hairy, the middle one hardly larger. Stipules at the base of the petiole, ovate, membranaceous, ferruginous, pressed close. Flowers single, on very short peduncles from the axils of the leaves. Calyx hairy. Corolla purplish [c].

All these are natives of Japan.

64. Root perennial. Stems ramping, six feet high and more, slender, not thicker at bottom than at top, round, finely haired, twining from left to right, having joints distant from each other a hand or a span; at every one of these is a trifoliate leaf, on long, slender, smooth petioles; leaflets blunt, veined, deep green and shining on the upper surface, paler and somewhat glaucous on the under, with a down scarcely visible except in the young leaves: petiolules of the side leaflets very short, of the middle one longer, with a pair of minute stipules under the leaflet. Spikes of flowers axillary, on very long, slender, smooth peduncles: flowers distant, two or three together, generally opposite: banner broadish, first concave, then flat and bent back, with a greenish spot at the base; wings of a middling length, applied to the keel, which is compressed and cuspidate; the whole of a very lively purple, except the hinder part of the banner, which changes to an obscure dun colour. Calyx divided into four segments, of which that next the banner is somewhat broader than the rest [b].

Native of North America. Cultivated in Dr. Sherard's garden at Eltham at least as early as 1727, probably some years sooner, about 1724.

Perhaps H. scandens of Miller n. 13. (89.) which he received from La Vera Cruz by Dr. Houstoun, may be the same with this.

65. This resembles *H. lineatum* in many respects, but the leaves are more acute, silky-tomentose all over the back and on the edge of the upper surface, they are also darker. All the nerves underneath, with the midrib above are very tomentose. Flowers small, sessile, in a peduncled axillary umbel. Angles of the branches tomentose. Petioles ciliate. Stipules filiform.—Thunberg gathered it in Java [d].

66. Leaves radical, with leaflets from seven to nine, equal, ovate. Scapes the length of the leaves or higher, somewhat tomentose, white. Spike terminating. Calycine leaves near the length of the corolla, which is violet-coloured or white, with the wings shorter than the banner. The legume consists of two or three lanuginous joints, enveloped in the dry flower.—Native of Siberia. Perennial [e].

67. Stem straight. Stipules short. Leaflets seventeen, ovate-lanceolate [f].—Stem somewhat shrubby, four feet high, round, simple, branched. Flowers yellow in small, upright racemes. Legume linear, straight, slender, long [g]: membranaceous, leafy-compressed; joints from two to four, ovate, smooth, netted, separating but not opening spontaneously. Seeds many, oblong kidney-shaped, ferruginous [h].—Native of Siberia and Cochinchina.

68. This plant commonly attains only the height of from two to six inches or a little more, seldom being found a foot high; hence differing materially from the *H. alpinum* of Linneus, which reaches the human stature. Root perennial, creeping. Stem annual, seldom branched, upright, terminated by a raceme. Root-leaves on the flowering plant none. Stem-leaves few, alternate: leaflets from three to eight on each side, with an odd one, ovate-oblong, blunt with a small point, entire, opposite, on short petioles, hirsute underneath when viewed with a magnifier, marked with lines by veins ascending obliquely. Stipules lanceolate, membranaceous, clasping, subaxillary, brown, often cloven above the middle into awl-shaped segments; those which are below the leaves are subimbricate and sheathing. Flowers eight lines in length, imbricate, pendulous, on short peduncles, varying in number, having no scent. Lower segments of the calyx gradually longer. Corolla violet-purple or red, seldom white: banner spotted with white above the claw; that and the wings nearly of the same length; the keel shorter. Germ commonly red. Legume oblong, compressed, smooth, brownish, with from one to four roundish or oblong joints.

Native of the higher Alps, where it flowers in july [i].

Linneus named this species from the obscurity attending it: that however has been well cleared up by Professor Jacquin as above. Linneus, in mantissa, remarks, that the stem is flexuose. Stipules stem-clasping, an inch long. Leaflets exactly elliptic, mucronate, with a little bristle.

Plant, according to Flora Aragoniæ, suffruticose. Leaflets ovate. Stipules sheathing. Peduncles longer than the leaves. Flowers in racemes, purple, with a flatted keel, broader outwards.

Haller makes this the same plant with *H. alpinum*; but Linneus's specimen from Switzerland is very well represented in Haller's figure, and it is certainly a species very distinct from the *H. alpinum* of Siberia.]

69. Root biennial. Stems from two to three feet high, hollow, smooth, branching. Leaves composed of five or six pairs of oval leaflets, terminated by an odd one; they are alternate, and from the angles which they form with the stem and branches, peduncles come out five or six inches in length, sustaining spikes of beautiful red flowers, which open in june and july, and perfect seeds in september, after which the roots commonly decay; but if the plants be cut down before they seed, they will last longer.

[Legume oblong, a little flatted. Joints three or fewer, roundish, with a crenulate border; covered with a thin fungous bark, muricated on the outside with short little prickles. The proper laminas are of the consistence of paper, smooth, scarcely opening spontaneously, but separating by joints.—*H. flexuosum* and *grandiflorum* have also their joints covered with a bark; in other species they are simple [k].—Native of Spain and Italy. Ray observed it in Sicily. In Calabria it grows wild in great luxuriance, near four feet high, affording excellent nourishment to horses and mules, both green and made into hay: but it does not well bear the spring in the north of Italy: we may presume, therefore, that it will scarcely bear our climate well enough to answer the purposes of husbandry.

Osbeck mentions, that he saw it brought it into Cadiz in great bundles, as food for the cattle. In German, French, Italian and Spanish it has the name of *Sulla*; in German it is also called *Kronenklee*, *Schildklee* and *Spanische Klee*. In French *Sainfoin d' Espagne*, and *Sainfoin à bouquets*. In Dutch *Sierlyk haanekop*.

Parkinson calls it *red Sattin-flower*, or *red flowered Fitching*, and observes that some foolishly call it, *red or French Honeysuckle*: the foolish name, however, has obtained in English. He informs us (1629) that the variety with a white flower grew at Stubbers by North

[a] Thunberg. [b] Dillenius. [c] Retzius. [d] Linn. suppl. [e] Linn. syst. [f] Gærtner. [g] Jacquin. [h] Gærtner.

Okenden, in the garden of Maſter William Coys, a gentleman of good reſpect in Eſſex, a great and ancient lover and cheriſher of theſe delights, and of all other rare plants.'

It was cultivated in 1596, by Gerarde [1].]

70. This has ſome reſemblance to the foregoing, but is much ſmaller. The ſtalks riſe near a foot high, and the leaves are compoſed of two or three pairs of ovate leaflets terminated by an odd one. The flowers come out in ſpikes at the top of the ſtalks, and are of a pale red, intermixed with little blue. They appear in july, and are ſucceeded by jointed pods, which are waved on both ſides, forming an obtuſe angle at each joint; the ſeeds ripen in autumn. It is an annual plant, and grows naturally in the Levant.

Cultivated by Mr. Miller, in 1739[2].—It grew in the Oxford garden (1671) from ſeed ſent from Aleppo, by Mr. Huntington[3].

71. Root perennial. Stems half a foot in length, uſually with one branch and leaf only. Leaflets obovate-oblong, villoſe underneath. Spike ovate. Calyx hirſute, ſhorter by half than the corolla, ending in briſtles. Corolla like that of *H. coronarium*, but ſmaller: banner of the ſame length with the keel; wings much ſmaller, not above one third of the length. Legumes of two joints uſually. Gerard will have it to be a variety of *H. pumilum*, but he is wrong[4].

Native of the South of France and Spain. Ray found it in Sicily, in a ſmall iſland near Capo Paſſaro. —It appears from Parkinſon, that it was cultivated here in 1640. It flowers in july and auguſt. Annual[5].]

72. This is an annual plant. Leaflets four or five pairs, with an odd one, narrow and oblong. Stem terminated by ſmall ſpikes of purple flowers, which are ſucceeded by ſmall rough legumes.

[The legume has generally two orbicular joints, equally prickly[6]. Native of Spain and Portugal. Cultivated in 1731, by Mr. Miller.

73. Stem upright, three feet high, with aſcending branches. Leaflets oblong, blunt, ſmall, many. Flowers violet-coloured, in terminating ſpikes. Legume ſlender, with roundiſh, flatted ſeeds[7]. Native of Virginia and Cochinchina.

74. Leaflets from nine to twelve, remote, petioled, hoary. Racemes few-flowered, ſhorter than the leaves. Corolla purple. Legumes flatted, with the joints wrinkled and netted.—It is a very handſome plant, grateful to horſes, and extremely uſeful in fixing driving ſand. Native of Siberia[8].

75. A ſmall ſhrub, only a hand in height. Leaves the length of the ſtem, with oval-oblong leaflets. Spike ſmooth. Banner only half the length of the keel, which is very large, broad and blunt. Calyx even, with very ſhort, awl-ſhaped teeth. Native of Spain[9].

76. This is an elegant plant, a foot in height, with a perennial root. Stems ſeveral, herbaceous, quite ſimple, the thickneſs of a pigeon's quill, ſtriated-angular, erect, very hairy; hairs white, long, ſoft, ſpreading very much. Root-leaves ſimple, petioled, elliptic, the next ternate; ſtem-leaves unequally pinnate, with three or four pairs of leaflets, which are an inch long, equal, oppoſite, lanceolate, mucronate, above very hairy, hoary green, beneath ſilky. Stipule ovate, membranaceous, purple, bifid, with lanceolate, acuminate ſegments. Spike ſilky, ſhining, many flowered; ſeveral radical, ſeſſile, or on very ſhort peduncles, flowering firſt; thoſe on the ſtem have very long peduncles, nodding before the flowers open. Flowers crowded. Cauline peduncles axillary, elongated, higher than the ſtem, tomentoſe-hoary at top. Bractes ovate, acuminate, purple-aſh-coloured, green at the baſe, ſoftly hairy, eſpecially on the back and at the edge, concave, ſmooth within, twice as long as the calyx. Calycine ſegments briſtle-ſhaped, brown, three times as long as the baſe, upright, almoſt naked at top, but covered with long, cloſe, white hairs at bottom. Corolla purple, half the length of the calyx: banner orbiculate; wings minute; keel ſhorter than the banner. Germ orbiculate, very hairy at the baſe, villoſe gray at top. Legume roundiſh, ſcarcely ſo big as a pepper-corn, wrinkled. Native of the Levant and Barbary[10]. See *Ebenus pinnata*, and n. 86.

Saint-foin.

77. *Root* perennial. *Stems* round, ſtriated, at firſt procumbent, in flower aſcending. *Stipules* in pairs, oval-lanceolate, terminated by a long point, with membranaceous edges, ſometimes fringed with a few hairs. *Petioles* furrowed above, ſlightly hairy. *Leaflets* eight to ten pairs, rather diſtant, and an odd one; lower elliptical, upper lanceolate or linear-lanceolate, all with a projecting point; young ones with the midrib beneath and the margins fringed with hairs. *Peduncles* long, ſlightly hairy, bearing numerous flowers in a long *ſpike*, thickly imbricate upwards, each with an awl-ſhaped bracte, longer than the pedicle. *Calyx* ſhort, hairy, one fourth of the length of the flower, with five nearly equal awl-ſhaped teeth. *Corolla*: ſtandard oval, ſlightly emarginate, partly bent back, ſhorter than the keel, fleſh-coloured, ſtriated with red veins; wings not longer than the teeth of the calyx, hooked near the baſe, pale fleſh-colour; keel broad, bent with an obtuſe angle at the top, fleſh-coloured, with a deeper red beneath. *Legume* hemiſpherical, compreſſed, with wrinkled prominencies[11].

Native of England, France, Flanders, many parts of Germany, as the Palatinate, Bohemia, Sileſia; in Auſtria, Carniola, Switzerland, Savoy, Italy, Spain, Siberia; on hilly paſtures, and open downs, particularly in a calcareous ſoil. Flowering in june and july. With us, on Gogmagog hills, Newmarket heath, about Royſton, in Norfolk, on Saliſbury plain, &c. Cotſwold hills, and on all our calcareous hills in general.

It is much cultivated in ſeveral parts of Europe, in dry ſoils, for feeding cattle: with us in Cambridgeſhire, Hertfordſhire, on Epſom downs, Cotſwold hills, about Malton, &c. in Yorkſhire, and other hilly ſituations and calcareous ſoils. It yields great abundance of excellent fodder, but is ſuppoſed to be much ſooner damaged by rain, when cut, than any other ſort of plant, uſually mown for hay.

The old Engliſh names were *Medick Vetchling* or *Cock's head*. The modern name of *Saint-foin* came from France, whence we originally had the ſeed.

In *German* it is Eſparzette, Eſper, Sparſette; der gemeine Suſsklee, Hahnenkopf, Hahnenkamm, Hahnenkammklee; groſſer Turkiſcher Klee, Turkiſcher Kleberklee, Schweizerklee, Wickenklee, Eſelſwicken, Heiligheu, Stachelheu, Stachelahre, Wiedhopfenkraut, Gurtniemen, Frauenſpiegel, rothe Ramſen, Sainfoin. In *Dutch* Haanekammetje's. In *Swediſh* and *Daniſh* Eſparſet & Sainfoin. In *French*, Sainfoin, Saintfoin, Eſparcette, Foin de Bourgogne. In *Italian* Cedrangola. In *Spaniſh* and *Portugueze* Pipirigallo.

Parkinſon ſays, (1640) it is known generally to be a ſingular food for cattle to cauſe them to give ſtore of milk.

Hartlib (1651) ſays we are to blame, that we have neglected Clover-graſs, Saint-Foine, Lucerne. He complains, that we want a place where we can find theſe ſeeds.

Walter Bliſh, in his Engliſh Improver Improved (1653), ſpeaks of it as a French graſs very little known, upon which he had not made a full experiment himſelf, having only ſown it that year, but as having been ſown in divers parts of England, as Cobham park in Kent, &c. upon chalky dry banks.

By a pamphlet printed in 1671 entitled "St. Foine improved," it appears, that divers places in this kingdom then already in part had received great benefit, and were likely to receive more, by the improvement of dry and barren ground, from ſowing of St. Foine.

Moriſon (1672) relates, that it may be cut three times in a year, that it is a food very grateful to cattle, that it delights principally in dry, ſandy and gravelly ſoils, and that its roots will penetrate among rocks, thriving and covering the ground where there is ſcarcely any

[1] Hort. kew. [2] Ibid. [3] Moriſon.
[4] Linnæus. [5] Hort. kew. [6] Linn. ſyſt.
[7] Loureiro. [8] Linn. ſuppl. [9] Linn. mant.
[10] Vahl. [11] Woodw. Mſs.

any earth; that it flowers in april on the Apennines, in may in Provence, in july in Brabant and Flanders, where it is frequently wild, and where many fields are ſown with it.

Ray (hiſt. 1686) informs us, that it began not long ſince to be ſown among us for feeding cattle, to the very great advantage of many: that it furniſhes abundance of milk, whence it was deſervedly called *Polygalon* by Geſner; and that, as it delights in a dry, chalky ſoil, not favourable either to graſs or corn, it may be cultivated to great advantage.

From theſe paſſages we may infer that St. Foin was very little, if at all cultivated in 1651, that it probably crept in about that time, or ſoon after, and that in twenty years from this time it was pretty well eſtabliſhed, though by no means generally till towards the end of the laſt century: when Houghton, in his collection (p. 144. vol. 2.) ſays that the cattle now (1697) live plentifully on the St. Foin growing on Epſom downs, which was formerly reckoned very barren ground. At the beginning of the preſent (1703) Liſle ſpeaks of it as commonly cultivated.

Mr. Marſhall, indeed, informs us, that it is ſaid (1789) to have been cultivated on the Coſwold hills upwards of 150 years, which carries us back to 1639, a period ſomewhat earlier than I believe Saint-foin to have been cultivated in England, till I find better authority than mere tradition.

This important ſpecies, with ſeveral others of the genus, which in former editions ſtood under the name of *Onobrychis*, is wholly omitted in the eighth edition of Miller's Dictionary, wherein probably the author intended to have removed them to the article *Hedyſarum*.

78. Stems under ground woody, above ground ſcarcely any. The ſpike reſembles that of the foregoing ſpecies, but is whitiſh. Wings of the corolla ſcarcely longer than the calyx, or ſhorter than the ſtandard and keel. Leaflets linear [a], ſomewhat hoary and acute, twelve to fifteen pairs, the lower ones more diſtant; petioles ſtriated. Stipules lanceolate, ſharp, bifid, ſmooth, decaying. Peduncles longer than the leaves, naked, ſtriated. The lower flowers in the ſpike remote, the upper ones cloſe. Calyx equal, with long, briſtle-ſhaped ſegments [b].

Native of Provence, the county of Nice, and Siberia. Perennial.

79. Root perennial. Legume has equal, ſharp ſpines along the keel [c].—Native of France and Sicily. Cultivated in 1748, by Mr. Miller. It flowers in july and auguſt [d].

Root white, annual. Stems procumbent. Leaflets linear, acute: peduncles very long: flowers in ſpikes. Segments of the calyx briſtle-ſhaped, villoſe. Flower twice as long as the calyx; banner ovate, retuſe; keel ſhorter than the banner; wings very ſmall, ſcarcely the length of a line, one fourth of the length of the calyx. Legume larger than the flower, remarkably thorny, containing one or two ſeeds. It differs from the foregoing ſpecies, in its annual root, the minuteneſs of the wings in the corolla, and in the larger ſize of the legumes [e].

80. Root annual. Petioles equal in length. The ſpines along the keel of the legume are larger, lanceolate, ſerrate [f]. Native of the Levant.

81. The ſtructure of the fructification perfectly reſembles that of *H. lagopodioides* and *barbatum*; and it is ſingular, that after the flowering is over, each pedicel is bent back in an arch, the three larger hairy ſegments of the calyx being bent back, ſo that the ſmooth legume is hid, and wrapped up among the pedicels ſo as not to be viſible, perfectly as in the above-mentioned ſpecies. It differs, however, in having a lofty, upright, ſhrubby ſtem, almoſt arboreous; and pinnate leaves, with five, oblong leaflets [g].

Stem five feet high, round, tomentoſe, with diffuſed branches. Leaflets about three pairs, lanceolate, four inches long, quite entire, ſmooth, veined. Stipules lanceolate, very ſmall. Flower violet-coloured, in a cloſe, round, ſtraight, terminating ſpike, a foot long: bractes lanceolate, acuminate, ciliate, two-flowered. Peduncles long, hairy, bent in. Calyx very hairy, the five ſegments awl-ſhaped and ſpreading. Corolla: banner roundiſh, entire, converging; wings ſhorter, oblong, keel creſcent-ſhaped, of a length between the banner and wings. Legume long, ſlender, of about ſeven joints, which are roundiſh, connected by a dorſal thread, drawn back and plaited within the calyx, preſſed cloſe to the common peduncle, the proper pedicels being bent in archwiſe. This, though it differs in ſeveral circumſtances from *H. lagopodioides*, yet does not differ from it a great deal. It has almoſt always pinnate leaves, of two or three pairs of leaflets, and very rarely indeed ternate; whereas that has ternate and quinate leaves promiſcuouſly [h].—Native of India, China, and Cochinchina.—Introduced in 1780, by Sir Joſeph Banks, Bart. [i]

82. Branches angular, villoſe. Leaflets three pairs, with an odd one, linear-lanceolate, a ſpan long and more, ſmooth on both ſides, almoſt equal, veined. Petiole the length of the leaf, villoſe. Petiolules very ſhort, hirſute. Stipules ovate, acuminate, nerved; with two others which are awl-ſhaped at each pair of leaves, longer than the petiolule. Raceme terminating, a ſpan long, upright, terminated by ſeveral lanceolate attenuated bractes four times as long as the flower, in form of a coma. Flowers crowded, on very ſhort pedicels. Loweſt bractes ovate, acuminate, permanent, nerved, villoſe; the upper ones deciduous, except that at the end. It ſeems to be diſtinct enough from H. crinitum, from which it differs in having narrower longer leaves, and a more ſlender raceme, terminated by bractes in form of a coma [k].

According to Jacquin, this very handſome plant has a perennial root; an upright, round ſtem, a foot and half high, leafy all over, cloſely hiſpid, with very minute white hairs; flowers at firſt red, but changing to blue, ſoon falling. Peduncle round, often as thick as a quill; pedicels in pairs, ſlender, ſpreading, three or four lines in length; both cloſely ſet with headed hairs. Calyx hirſute and ciliate; tube bell-ſhaped, border reddiſh, ſpreading; ſegments lanceolate, acuminate, the two upper ones ſhorter. Banner roundiſh, quite entire, ſpreading; wings blunt, oppoſite to the banner; keel of the ſame form and in the ſame ſituation with the wings. Legume flexuoſe, with about five rounded, compreſſed, wrinkled joints lying on each other. Found in the Eaſt-Indies by Koenig, and in Guinea by Iſert.

83. Stem low, hard. Stipules membranaceous, ſmall, acuminate. Leaflets ſeven or nine. Peduncles axillary, ſolitary, ſimple, mucronate, changing into round thorns, the length of the leaves, divaricating from the branch. Flowers three or four, alternate, pedicelled, placed below the tip of the peduncle. In figure it reſembles the ſecond Onobrychis of Cluſius, hiſt. 2. 239. [l] Native of the Levant.

84. Stem herbaceous, round, purpliſh, ſmooth. Leaflets about four pairs, on very ſhort petioles, oblong, acute, ending in a briſtle, entire, ſmooth, ſpreading, an inch in length, the upper ones a little larger. Flowers axillary, fleſh-coloured. Racemes a ſpan in length. It differs from *H. obſcurum* in being without any ſtipules.—Native of Japan [m].

85. Stem ſuffruticoſe, two feet high, branched. Leaflets ſmooth. Flowers dark violet-coloured, ſmall, in upright ſpikes. Legumes linear, acuminate, containing ſix ſeeds.—Native of Cochinchina.—The root is eſteemed to be deobſtruent, emmenagogue, and to create an appetite [n].]

86. Stem ſhrubby, ſix or ſeven feet high, dividing into ſeveral branches. Leaflets pale green above. Spikes ſeſſile, long and narrow. Flowers ſmall, brighe purple. Legumes flat, ſmooth, jointed, about an inch long. [Thunberg and Vahl have given the ſame trivial name of ſericeum to other ſpecies. See n. 60. and 76.]

87. This

87. This is an annual plant, ſeldom riſing more than eight or nine inches high, ſending out ſeveral branches from the root, which are diffuſed and hairy. Leaflets ſmall, ovate, a little hoary. Spikes cloſe and ſhort. Corolla purple.

Theſe are both natives of La Vera Cruz, [and were cultivated by Mr. Miller in 1731.]

88. Stem about two feet high: the upper part branches into panicles of flowers, which are of a pale purple colour. Legumes lunulate, compreſſed, ſtanding oblique to the ſtem; one-ſeeded. Native of Campeachy.

89. Stem twining, and climbing to the height of ten or twelve feet. Leaves on pretty long foot-ſtalks. Flowers dark purple, ſitting cloſe to the ſtalk. Native of La Vera Cruz.

Theſe were all ſent to Mr. Miller by Dr. Houſtoun, [and were cultivated by him in 1731, if not ſooner.]

90. Root perennial. Stem annual, erect, about two feet high. Leaflets long, rounded at the baſe where they are broadeſt, and narrowed all the way to a point; they are near three inches and a half long, and half an inch broad at the baſe, of a light green colour, and ſmooth: the two ſide ones ſit pretty cloſe to the ſtalk, but the middle one ſits upon a foot-ſtalk an inch long: the flowers are produced in long axillary ſpikes, growing erect; the lower part of the ſpike is but thinly ſet with flowers, but on the upper part they are diſpoſed very cloſe; they are ſmall, and of a bright yellow colour, ſeſſile, and ſucceeded by jointed pods, ſtraight on one ſide. Native of South Carolina, whence it was ſent to Mr. Miller by Dr. Dale.

PROPAGATION AND CULTURE.

1. This is propagated by ſeeds, which will frequently lie a year in the ground before they vegetate: ſow them therefore in pots filled with light earth, and plunge them into a moderate hot-bed: if the plants do not appear by the beginning of June, take the pots out of the bed, and place them where they may have only the morning ſun, and in the autumn plunge them into an old bed of tanner's bark under a frame; in ſpring plunge them into a freſh hot-bed, which will bring up the plants: when theſe are fit to remove, put them ſeparately into ſmall pots filled with light earth, and plunge them into a very moderate hot-bed, ſhading them from the ſun till they have taken new root; then gradually inure them to the open air, into which remove them in June, placing them in a ſheltered ſituation, where they may remain till the autumn; at which time plunge them into an old tan-bed under a frame, where they may be protected from froſt, and in mild weather enjoy the free air. In a warm border, by covering it in froſty weather, this plant will endure our winters, when they are not ſevere.

The other ſimple-leaved ſorts (2 to 18) and the two-leaved ſort, together with the greateſt part of the reſt, are too tender to thrive in the open air: for their native places of growth are the Eaſt or Weſt-Indies.

They are propagated by ſeeds, which muſt be ſown upon a hot-bed early in the ſpring. When the plants are fit to remove, they muſt be each planted in a ſeparate ſmall pot, filled with light earth; plunging them into a freſh hot-bed, where they ſhould be ſcreened from the ſun, till they have taken new root; after which they may be treated in the ſame manner as other tender plants: always keeping them in the bark ſtove or glaſs-caſe, otherwiſe they will not produce ſeeds, nor even always flower in England. They require as much air as poſſible in warm weather. Many of the ſorts ſeldom flower till the ſecond year.

35. The ſeeds may be ſown the beginning of april, in a bed of light freſh earth. When the plants are come up two inches high, they ſhould be tranſplanted where they are to remain for good; but if they are not too thick in the ſeed-bed, they may be ſuffered to remain there until the following autumn; at which time they ſhould be carefully taken up, and tranſplanted into the borders where they are deſigned to ſtand; for their roots generally run down very deep, ſo that it is not ſafe to remove them often. This plant produces its flowers about the ſame time of the year as the former, and if the ſeaſon proves favourable, perfects its ſeeds in autumn; and the roots will abide in the open air very well, reſiſting the ſevereſt cold, provided they are planted in a dry ſoil.

43. This may be raiſed in the manner directed for the ſimple-leaved ſorts: in ſummer the plants may be expoſed to the open air, but in autumn they muſt be placed under a frame to ſcreen them from froſt; the following ſpring ſome of theſe plants may be ſhaken out of the pots, and planted in a warm border, where, if the ſummer prove warm, they will flower, but theſe ſeldom perfect their ſeeds; therefore two or three plants ſhould be put into larger pots, and plunged into a moderate hot-bed, which will bring them early to flower, and if the glaſſes be kept over them in bad weather, theſe will ripen their ſeeds in autumn; and the roots will continue ſome years, if ſcreened from froſt in winter.

The 90th ſort may be treated in the ſame manner.

69. The common French Honeyſuckle, and other hardy ſorts, are propagated by ſowing their ſeeds in april, in a bed of light freſh earth; and when the plants come up, they ſhould be tranſplanted into other beds of the like earth, and in an open ſituation, at about ſix or eight inches diſtance from each other, leaving a path between every four rows, to go between them to hoe, and clear them from weeds. In theſe beds they may remain until michaelmas, then may be tranſplanted into the large bodies of a parterre or pleaſure-garden, allowing them at leaſt three feet diſtance from other plants, amongſt which they ſhould be interſperſed, to continue the ſucceſſion of flowers; where they will make a fine appearance when blown, eſpecially the red ſort, which produces very beautiful flowers.

As theſe plants decay after they have perfected their ſeeds, ſo there ſhould annually be a freſh ſupply of plants raiſed, where they are deſired, for the old roots ſeldom continue longer. They are very proper ornaments for large borders, or to fill up vacancies among ſhrubs, but they grow too large for ſmall borders, unleſs their ſtalks are pruned off, leaving only two or three on each plant; which, if kept upright with ſticks, will prevent their hanging over other flowers.

They furniſh abundance of food agreeable to cattle, if not ſuffered to ſtand till the ſtalks are too hard and ſticky.

70, 71, 72. Should be ſown in april, where they are to remain, and require only to be thinned where they are too near, and to be kept clean from weeds.

77. *Saint-foin,*

If ſown upon a dry, gravelly or chalky ſoil, will continue eighteen or twenty years; but on a deep moiſt ſoil the roots will run down into the ground, and in the winter ſeaſon the moiſture will rot them, ſo that it ſeldom laſts above two years in ſuch places.

It is eſteemed one of the beſt ſorts of fodder for moſt cattle, and is a great improvement to chalky hills, upon which it ſucceeds better than in any other ſoil, and will continue many years, provided there be a ſurface of ſix or eight inches upon the chalk.

The beſt time for ſowing the ſeed is the beginning or middle of april, according to the ſeaſon, obſerving always to do it in dry weather, otherwiſe the ſeed will be apt to burſt, and never come up. The ſeed being large, the common allowance is four buſhels to an acre, but three is amply ſufficient. If it were ſown in rows, as directed for Lucerne, it would be a great improvement to the plants, for when theſe have room enough, they branch out on every ſide, and become very ſtrong; and by hoeing between them the natural graſs may be kept down, which, if permitted to grow, will rob the Saint-foin of its nourithment, and in time deſtroy it.

Saint-foin is frequently ſown with oats or barley, but this is a very bad method, for what is gained from the crop of corn, will be doubly loſt in the Saint foin; and this generally holds true in moſt ſorts of Graſs ſeeds, for the corn growing over it ſo weakens the crop beneath, that it ſcarcely recovers its ſtrength in a year after.

The

The ground in which this seed is sown should be well ploughed, and made very fine. If it be sown in drills, the drills should be eighteen inches asunder, and about an inch deep: if the plants come up too thick, they should be hoed out to the distance of six or eight inches, when the ground is hoed to destroy the weeds.

The first year by no means feed the crop down, for the crown of the roots being then young and tender, cattle would eat it so low as entirely to destroy the roots; and if large cattle were let in upon it, they would trample it down so much as to prevent its shooting again; the first year therefore it should be mowed, and this should be done when it is in flower.

The sooner it is carried off the ground, when cut, the better it will be for the plants. It does not require to be so often turned as other hay, for the stalks being large, they will not lie so close in the cocks as to ferment; in catching weather therefore the cocks may be made large, and if they be turned and spread every other day, or once in three days, there will be little danger of its heating, so as to receive damage; but if it be spread, and much exposed to rain and dew, the goodness of the hay will be exhausted.

The crop will be fit to cut the first year towards the end of july, or at the beginning of august. After this is cleared off, the roots will soon shoot again, and by the end of september, provided the season be favourable, there will be a fine crop, fit for feeding. Sheep will enrich the ground with their dung, and greatly strengthen the roots; but they should not be suffered to remain upon it longer than the middle of november the first year; and the succeeding years, when the crop is cut early, it should not be fed longer than the middle of september.

Some cut two crops of Saint-foin hay in a year, but the latter crop is seldom of much value, and it weakens the roots. When seeds of Saint-foin are to be saved, the crop should not be fed too low the foregoing autumn, for that will occasion the stalks to be weak. I have made trial of two rows of plants standing by each other, one of which I cut down in september with care, so as not to cut any buds for the future shoots; the other row I left untouched, and the following spring I found those plants which were not cut put out earlier and stronger, and the stalks grew taller than those which were cut, the plants produced a greater quantity of seeds, and the seeds were ripe a fortnight sooner.

The hay made from plants saved for seed is no better fodder than chopped straw or chaff; and to have the hay in perfection, it should be cut before it begins to flower, when it abounds most in juice, and will nourish cattle much more than when it stands to be in full flower.

Saint-foin is exceeding good for horses, and is esteemed one of the best sorts of food for most cattle, especially in the spring, there being no danger attending it, as there is in Clover.

It produces abundance of milk, and butter made of it is very good. Since it has been introduced into England, many dairy farms have been set up, where it was formerly thought impracticable: and if this plant and Lucerne were properly cultivated to such an extent as they might be, not only a much greater quantity of milch cows might be maintained, but a greater number of black cattle might be fattened, and more sheep and hogs, which would be a great improvment to many estates in hilly countries; for by increasing the live stock, there will be an addition of manure for dressing the land, in proportion.

[Saint-foin is allowed on all hands to be an admirable improvement on lime-stone rocks and chalk downs, which, in order to be cultivated to the greatest advantage, should be in this course, with no more arable than is necessary for the change. Thus if Saint-foin last sixteen years, as it certainly will if properly managed, then sixteen parts of the down should be Saint-foin, and as many more parts as there are years necessary for tillage before the ground should be sowed with it again; suppose this period to be five years, the portions would then be

10. Saint-foin.
1. Saint-foin pared and burnt, and under Turneps.
1. Barley or Oats.
1. Clover.
1. Wheat.
1. Turneps.
1. Barley or Oats, and with this crop Saint-foin sown again.

16

Suppose each part was twenty-seven acres, then there would be two hundred and seventy acres of Saint-foin, and so on[s].

Saint-foin is also a vast improvement in thin, loose, dry, sandy loams, upon marl or chalk bottoms. Thin soils that wear out, or tire of Clover, are laid down to great advantage with it, will last twenty years, and pay the farmer as well as his best corn crops. If a flock of Sheep be an object of primary importance, this plant will afford them plenty of dry food for winter in hard weather. An acre of indifferent land will yield two tons of Saint-foin dry, and therefore twenty acres will serve 1000 Sheep for a month, supposing a Sheep eats three pounds of hay in a day, which is a large allowance. Now the expense of an acre of Saint-foin, including 14*s.* for rent, tithe and poor, is about one pound; whereas that of an acre of turneps will be two pounds seven shillings. Eight acres and a half of turneps then balance twenty acres of Saint-foin. Now 1000 Sheep will eat two acres and a half of turneps in a day, and therefore seventy-five acres will be required for a month: or at the lowest calculation twenty-four acres, the expense of which is 56*l.* 8*s.* to be set against 20*l.* the expense of Saint-foin[t].

Some green food, however, should be joined with the hay, for milch ewes or cattle. Green borecole, the turnep-rooted cabbage, or the Swedish turnep, would answer this purpose; being hardy, and standing above the snow.

One great advantage of this, in common with other artificial grasses is, that even in a dry season, from a ton to a ton and half of hay may be had from an acre, when natural meadows unwatered will produce only half a ton[u].

The most common time of sowing Saint-foin is the spring; and it is even commonly reputed bad husbandry to sow it in the autumn, because the frost is apt to draw it out of the ground. It has however been sown with success in october along with wheat or rye, after winter tares. The crop was good, even the first season, though it happened to be a very dry one; whereas it is well known that Saint-foin sown in the spring yields a very scanty crop the first year, even when assisted with manure.

At either season Saint-foin is commonly sown with corn; but it is still doubtful whether the crop of artificial grass may not be diminished in proportion as the crop of corn flourishes. Other seeds are sometimes sown with it to give a crop the first year, as white clover, common red clover, and trefoil: of these the first is much the best[x].

The quantity of seed usually sown is at least four bushels, and some sow five; though Mr. Miller is for sowing a less quantity. In drilling two bushels are sufficient; but this is not a common practice with Saint-foin.

One of the best preparations for Saint-foin, is to take two crops of turneps in succession, and then in the spring to sow four bushels of this seed with two bushels of barley[y].

Coal-ashes are a good dress for Saint-foin; and soot a still better, in the quantity of from ten to twenty bushels on an acre, laid on early in the spring[z].

Saint-foin is much troubled with a sort of grass which botanists call Bromus sterilis, and farmers know by the name of Black-grass. The scythe slips over it, the seed ripens very early, and is difficult to sepa-

[z] Ibid. 4. p. 339.

rate from the Saint-foin ſeed. It may eaſily be pulled up by hand [a].

When the crop begins to fail, or the land is wanted for ſomething elſe, a Saint-foin lay may be broken up ſucceſsfully for Potatoes; for the red-worm, which makes ſuch ravages if corn be ſowed without paring and burning, will not touch the Potatoes [b].

Modern writers affect to write *Sain-foin* as if it were wholeſome hay; whereas it is *Saint-foin* or holy hay, from a preſumption of its ſuperiour excellence. Vulgar perſons confound it with Cinquefoil, from the ſound merely, for no two vegetables can be more different.

Borbonia fructu oblongo nigro, calyce coccineo. *Plum. gen.* 4.

DESCRIPTION, *&c.*

This is an inelegant branching tree, twenty feet in height. Leaves oblong, quite entire, drawing to a ſickle-ſhaped point, ſhining, on ſhort petioles, alternate, half a foot in length. Flowers ſmall, peduncled, axillary, with white corollas. Calyx in the flower ſmall and green, in the fruit ſcarlet, with a very large ſpreading limb, and ſhort, very blunt, roundiſh ſegments. Native of Martinico, in cloſe woods near torrents, flowering in february and march, and fruiting in june. The French inhabitants call it *Bois Perdrix*, birds being very fond of the fruit [c].

HELISTERIA. See *Polygala.*

HELENIA & HELENIASTRUM. See *Helenium.*]

HELENIUM. (*Named of Dioſcorides. From Helen, the wife of Menelaus, who, as Heſchius ſays, cultivated a plant that deſtroyed ſerpents: according to others, this plant ſprung from her tears.*)

Lin. gen. n. 961. *Reich.* 1041. *Schreb.* 1299. *Juſſ.* 189. Heleniaſtrum. *Vaill. nom. acad.* 1720. Helenia. *Gærtn. t.* 169.

Claſſ. 19. 2. Syngeneſia Polygamia Superflua.

Nat. order of *Compoſitæ Diſcoideæ.—Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* ſimple, one leafed, many-parted, ſpreading: *leaflets* about twenty, gradually drawing to a point. (oblong, ſharp, equal. *G.*)

COR. *Compound* radiate; *Corollets* hermaphrodite, numerous in the diſk: *females* as many as there are parts of the calyx, in the ray.

Proper—of the *hermaphrodites* tubular, ſhorter than the calyx, five-toothed.—of the *females* ligulate, broader outwards, trifid at the tip, longer than the calyx.

STAM. in the hermaphrodites: *filaments* five, capillary, very ſhort. *Anther* cylindric, tubular.

PIST. in the hermaphrodites: *Germ* oblong. *Style* filiform, length of the ſtamens. *Stigmas* bifid.—in the females: *Germ* oblong. *Style* very ſhort. *Stigma* bifid.

PER. none. Calyx unchanged.

SEEDS in the hermaphrodites ſolitary, obovate, angular, crowned with a ſmall, five-toothed *calycle*:—in the females, very like the others.

REC. naked, convex: the calycine *chaffs* only of the ray ſeparating the florets.

ESSENTIAL CHARACTER.

Cal. ſimple, many-parted. *Corollets* of the ray ſemitrifid. *Down* five-awned. *Recept.* naked, excepting the calycine chaffs in the ray.

DESCRIPTIONS, *&c.*

1. Miller, following Vaillant, has made two ſpecies out of this: the firſt with entire leaves, which he names *Helenium autumnale*; the ſecond with ſerrate leaves, which he names *H. latifolium*. The firſt is the Heleniaſtrum folio longiore & anguſtiore; the ſecond is, H. fol. breviore & latiore of Vaillant. Miller thus deſcribes them.]

Theſe plants riſe to the height of ſix or ſeven feet in good ground; the roots, when large, ſend up a great number of ſtalks, which branch toward the top; thoſe of the firſt have ſmooth leaves, three inches and a half long, and half an inch broad in the middle, with entire edges, ſitting cloſe to the ſtalks, and from their baſe is extended a leafy border along the ſtalk, ſo as to form what was generally termed a winged ſtalk, but Linneus calls it a decurrent leaf; the upper part of the ſtalks divides, and from each diviſion ariſes a naked peduncle about three inches long, ſuſtaining one yellow flower at the top, ſhaped like a Sun-flower, but much ſmaller, having long rays, which are jagged pretty deep into four or five ſegments; theſe appear in auguſt, and there is a ſucceſſion of flowers on the plants till the froſt puts a ſtop to them.

The ſecond has the appearance of the firſt, but the leaves are not three inches long, and are more than an inch broad in the middle, ending in acute points, and are ſharply ſerrate on their edges. The flowers ſtand upon ſhorter peduncles, growing cloſer together, for the ſtalks of this do not branch near ſo much as thoſe of the other; they both flower at the ſame ſeaſon.

There is alſo another with leaves as narrow as the firſt, which are acutely indented on the edges. The ſtalks branch at the top ſomewhat like thoſe of the firſt, but the middle flowers have much ſhorter foot-ſtalks than thoſe which branch on the ſide, and are garniſhed with ſmall leaves, almoſt at the top; but I am not certain if this is a diſtinct ſpecies, or only a variety which has accidentally riſen from the ſeeds of the other.

Theſe plants are natives of America; the ſeeds of both I have received from Virginia and New-England, where they grow wild in great plenty in the woods, and other ſhady places where the ground is moiſt.

[Helenium autumnale was cultivated in the botanic garden at Cheliſea in 1729.

2. This alſo is native of North America; it was introduced in 1776, by Mr. William Malcolm, and flowers in auguſt and ſeptember [c].]

PROPAGATION AND CULTURE.

They may be propagated by ſeeds, or by parting their roots; but the latter is generally practiſed in this country, becauſe they ſeldom perfect their ſeeds here;

[a] Young's Ann. 7. p. 575. [b] Jacquin. [c] Ibid. 3. p. 83. [c] Hort. kew.

but

but if the ſeeds are procured from abroad, they ſhould be ſown the beginning of march on a border of light earth; and if the ſeeds ſhould not come up the firſt year, the ground ſhould not be diſturbed, becauſe they often remain a whole year in the ground before the plants come up; in which caſe there is nothing more to be done, but to keep the ground clear from weeds, and wait until the plants riſe. When they appear, if the ſeaſon proves dry, they muſt be often watered, which will greatly forward their growth; and where the plants come up too cloſe to each other, they ſhould be thinned, and tranſplanted out into beds a foot aſunder every way, being careful to ſhade them until they have taken root, as alſo to water them in dry weather. In autumn they may be tranſplanted where they are to remain, and the following ſummer they will produce their flowers, which will continue till the froſt prevents them; and their roots will abide many years, and afford many offſets, by which they may be increaſed.

The beſt ſeaſon to tranſplant the old roots, and to part them for increaſe, is in the end of october, when their flowers are paſt, or the beginning of march, juſt before they begin to ſhoot; but if the ſpring ſhould prove dry, they muſt be duly watered, otherwiſe they will not produce many flowers the ſame year; theſe plants ſhould not be removed oftener than every other year, if they are expected to flower ſtrong; they delight in a ſoil rather moiſt than dry, provided it be not too ſtrong, nor holds the wet in winter; but if they are planted in a dry ſoil, they muſt be often and plentifully watered in dry weather, to make them produce plenty of flowers.

Leaves oppoſite, ſpatulate, crenate, triple-nerved, ſcabrous; calycine ſcales erect, the length of the diſk.

DESCRIPTIONS, &c.

[Theſe are hardy herbaceous plants, moſt of them tall and large, and all perennial, except the two firſt.

The

The leaves rough, in ſome oppoſite, in others alternate. The flowers in general very large, and yellow; in the laſt, the flowers are ſmaller, and the diſk is of a duſky red colour. They are all natives of America: the annual ſorts ripen ſeeds, the perennials not.

1. Root annual. Stem ſingle or branched, from five or ſix to ten or fourteen feet in height, and in hot climates twenty or more; when vigorous, the ſize of a man's arm. Leaves alternate, a ſpan or a ſpan and half in length, and almoſt as much in breadth, rough, ſerrate, acuminate, hanging down at the end, on long petioles. Flower ſingle, (ſometimes ſeveral,) nodding, a foot or more in diameter. Gerarde mentions one that flowered in his garden, of ſixteen inches in breadth, and weighing three pounds two ounces. The ſemiflorets or ligulate floſcules in the ray are uſually of a fine golden colour, and near an inch in breadth, ending in a point which is commonly bent back. The florets or tubular floſcules in the ample diſk are of a darker colour, cloſely wedged together, and very numerous. The ſeeds are numerous (Bauhin mentions 2362 in one flower), black, variegated or white, and when theſe have quitted their cells, the receptacle looks like a honeycomb. The great ſize of the whole compound flower recommends it to the ſtudent for the examination of the floſcules, which in the claſs Syngeneſia are uſually very ſmall. The whole plant, and particularly the flower, exudes a thin, pellucid, odorous reſin, reſembling Venice turpentine.] The ſeeds are excellent food for domeſtic poultry.

Varieties are—double flowers, and deep yellow, and ſulphur-coloured. [This flower becomes double by the change of tubular into ligular florets, like thoſe in the ray, only ſmaller.

Gerarde obſerves, that it was called *Indian Sunflower*, or *Flower of the Sun*, *Corona Solis* and *Sol indianus*, becauſe it reſembles the radiant beams of the ſun. As to its turning with the ſun, it is a vulgar error; Gerarde ſays he could never obſerve it; and I have ſeen four flowers on the ſame ſtem pointing to the four cardinal points.

Native of Mexico and Peru; flowering from june to october.

2. This perhaps may only be a variety of the foregoing, though conſtant: but the leaves are convex above in the diſk, and of a darker green. The peduncles are leſs thickened at top, or rather of an equal thickneſs every where, whence the flowers nod leſs. The ſcales of the calyx, except the inmoſt row, grow out into petioled pendulous leaflets [a]. We do not know the native country of this, but there is little doubt of its coming from Mexico or Peru.—Linnæus ſays that it is cultivated in Egypt.—It grows only from eighteen inches to three feet an height.—Introduced, according to the Kew catalogue, by Chevalier Thunberg in 1785.

3. Stem and pedunckes ſcabrous. Leaves cordate-ovate. Calyxes looſely imbricate, neither ſquarroſe nor drooping, conſiſting of forty to fifty ſcales [b].—Stems many upright, from five or ſix feet to eight or nine in height, branching, the ſtem and each branch terminated by a flower, the principal one ſometimes nine or ten inches in diameter, the lateral ones gradually ſmaller. Leaves ſome oppoſite, others alternate. There is a conſtant ſucceſſion of flowers from july to november.—It is a native of Virginia, and was introduced before 1699, by William Farmer Lord Lemſter [c].

4. Stems ſeveral, rough, hairy, ſtreaked, from ten or twelve to ſixteen feet in height, the ſize of a child's arm. Leaves alternate, light green, rough, pointed, eight inches broad, and ten or eleven inches long, deeply ſerrate, ſmaller towards the top. Branches many, long from bottom to top. Flowers terminating, ſmall; florets in the ray twelve or thirteen. Theſe ſeldom blow before october, and in ſome ſeaſons they do not expand at all. The ſeeds never ripen here.—Roots creeping, with many tubers cluſtered together, thirty, forty or fifty from one plant, meaſuring a peck, or in good ſoils half a buſhel; they are like the common Potatoe, red on the outſide, and very irregular in their ſhape, the ſize of a man's fiſt at the biggeſt [d].

Mr. John Goodyer received, in 1617, two ſmall roots from Mr. Franquevill of London, no bigger than hen's eggs; the one he planted, and the other he gave to a friend. His brought him a peck of roots, wherewith he ſtored Hampſhire. This note is dated the 17th of october 1621: and Johnſon obſerves that his friend took it preſently upon the firſt arrival into England. If this were the era of the firſt introduction of Jeruſalem Artichoke, it ſeems ſurpriſing, even allowing for the facility with which it is encreaſed, that ſo ſoon as the year 1629, or even earlier, it ſhould have become ſo common in London, that even the moſt vulgar began to deſpiſe it: whereas when firſt received among us, it was, as Parkinſon ſays, a dainty for a queen [e]. By the latter expreſſion, one would ſuppoſe that it had been known here in the time of Queen Eliſabeth.—Our anceſtors boiled them tender, and then being peeled, ate them ſliced and ſtewed with butter, wine and ſpices—thus, ſays Parkinſon, they were a diſh for a Queen, being as pleaſant as the bottom of an Artichoke: but the too frequent uſe, eſpecially being ſo plentiful and cheap, hath rather bred a loathing than a liking of them. They alſo baked them in pies, with marrow, dates, ginger, raiſins, ſack, &c. —This root probably got into diſuſe, from a notion of its flatulent quality. The Potatoe ſeems to be more nutritious and wholeſome; it is not neceſſary therefore now to inforce the cultivation of Jeruſalem Artichoke as a general article of food, but it certainly makes an agreeable variety at good tables. There is no better reaſon for its common Engliſh name, than that the root, when boiled, has the taſte of an Artichoke bottom: Parkinſon therefore would have it called Potatoes of Canada, becauſe the French brought them firſt from Canada into theſe parts. Not that Canada is their original country, for they are unqueſtionably the produce of a hot climate, being natives of Braſil.

5. This reſembles *H. multiflorus*, or common Perennial Sun-flower, very much; but it differs in having the ſtem, which ſcarcely attains the height of a man, ſcabrous, but ſmooth at bottom. The leaves more lanceolate-ovate, not cordate, oppoſite, and ciliate at the baſe. The corolla with not more than ten florets in the ray. The calyx has twenty ſcales, is ſquarroſe, hiſpid, the leaflets not waved, and very ſeldom growing out into leaves.—Native of Canada [f]. It was cultivated in 1759, by Mr. Miller [g].

6. This is allied to the foregoing ſpecies. In Lin. ſpec. the ſtem is ſaid to be ſmooth at bottom. Native of Canada.

7. Roots white and fleſhy. Stems ſeveral, nine or ten feet high, round, rough, ſomewhat hirſute, ſtreaked, ſubdivided into numerous branches. Leaves alternate, a hand long, an inch or more broad, acuminate, rough, dark green, ſlightly notched about the edge. Flowers terminating, in corymbs, petals pale yellow, ending in a biſid point: leaflets of the calyx produced into long leaves. The roots are bitteriſh, aromatic, and not diſagreeable: they are eaten by the Canadians, among whom this plant grows wild.—It was cultivated in 1759, by Mr. Miller, and flowers from july to ſeptember [h].

8. Stem ten feet high, green, hiſpid or ſcabrous. Leaves by no means triple-nerved, ſerrate, ſcabrous on both ſides, ending in ciliate petioles. Peduncles ſcabrous, hiſpid. Uſually about twenty florets in the ray, biſid at the end. The firſt two leaves of the branches are oppoſite, and have the appearance of ſtipules. The flowers nod more in the night than in the day. Native of Virginia and Canada [i]. Loureiro ſays, it is cultivated in China and Cochin.—Cultivated here in 1714, by the Dutcheſs of Beaufort. It flowers in ſeptember and october [k].

9. Siſter of the foregoing, of the ſame ſtructure and height; but the leaves are in breadth one fourth part

[a] Linn. mant. [b] Linn. ſpec. [c] Moriſon in Hort. kew. [d] Goodyer in Ger. emac. [e] Parad. printed 1629. [f] Linn. ſpec. [g] Hort. kew. [h] Ibid. [i] Linn. ſpec. [k] Hort. kew.

one ſixth) of the length, different in their ſerratures, triple nerved at the baſe, petioled, almoſt ovate-lanceolate. The whole ſtalk not only ſmooth and even, but purpliſh. Leaflets of the calyx ſhorter, and not ſo copious. Uſually ſixteen florets in the ray. The chaffs in this are green, in the foregoing blackiſh, whence the diſk in that, before the flower unfolds, is black; in this, green. Native of Pennſylvania [1]. Cultivated in 1739, by Mr. Miller. It flowers in auguſt and ſeptember [a].

10. Stem purpliſh, a foot and half in height. Leaves linear, acuminate, ſcabrous, rolled back at the edge, pale underneath. Diſk of the corolla brown; ray deep yellow, emarginate [a].—Native of Virginia.

11. Stem ſcarcely the height of a man, extremely even at top, but with ſcattered tough hairs, purple, with a glaucous bloom. Flowers in a panicle, with trichotomous branches, yellow, ſmall, pedunculed, with the middle peduncle ſimple. Peduncles ſomewhat ſcabrous. Native of North America [a].—Cultivated in 1759, by Mr. Miller. It flowers from auguſt to October [2].

12. Stem commonly ſingle, about the ſize of a ſwan's quill at bottom, from eighteen inches to three feet or more in height, round, duſky purple, rough, with abundant whitiſh hairs. Root-leaves flat, hairy, ſmaller than thoſe on the ſtem, which are twiſted and waved, eſpecially towards the end, rough, with frequent hairs, and on the lower ones particularly with ſmall tubercles. Flowering branches divaricate. The diſk of the flower dark red: floſcules in the ray yellow, marked with a few lines, pointed and entire, ſometimes in very old flowers divided into ſegments.

Native of Carolina [3] and Virginia.—It flowers in ſeptember and October, and continues two or three years. —Cultivated in the Eltham garden in 1732, if not earlier.]

PROPAGATION AND CULTURE.

The annual ſorts (1, 2.) are eaſily propagated by ſeeds, ſown in march upon a bed of common earth, and when the plants come up, thin them where they are too cloſe, and keep them clean from weeds; when the plants are grown ſix inches high, they may be taken up with balls of earth to their roots, and planted into the large borders of the pleaſure-garden, obſerving to water them till they have taken new-root; after which they will require no other care, but to keep them clear from weeds.

In july the great flowers upon the tops of the ſtems will appear, amongſt which, the beſt and moſt double flowers of each kind ſhould be preſerved for ſeeds; for thoſe which flower later upon the ſide branches are neither ſo fair, nor do they perfect their ſeeds ſo well, as thoſe which are firſt in flower: when the flowers are quite faded, and the ſeeds are formed, you ſhould carefully guard the heads from the ſparrows, which will otherwiſe devour moſt of the good ſeeds; and about the beginning of October, when the ſeeds are ripe, you ſhould cut off the heads with a ſmall part of the ſtem, and hang them up in a dry airy place for about a month, by which time the ſeeds will be perfectly dry and hard; when you may eaſily rub them out, and put them into bags or papers, preſerving them from vermin until the ſeaſon for ſowing them.

The perennial ſorts rarely produce ſeeds in England, but moſt of them increaſe very faſt at their roots, eſpecially the creeping rooted kinds, which ſpread too far for ſmall gardens. The third ſort, which is the moſt common in the Engliſh gardens, is the largeſt and moſt valuable flower, and is a very proper furniture for large borders in great gardens, as alſo for boſquets of large growing plants, or to intermix in ſmall quarters with ſhrubs, or in walks under trees, where few other plants will thrive; it is alſo a great ornament to gardens within the city, where it grows in defiance of the ſmoke, better than moſt other plants; and for its long continuance in flower, deſerves a place in moſt gardens, for the ſake of its flowers for baſons, &c. to adorn halls and chimneys, in a ſeaſon when we are at a loſs for other flowers. It begins flowering in july, and continues till october; there is a variety of this with very double flowers, which is now become ſo common in the Engliſh gardens, as to have almoſt baniſhed the ſingle ſort from hence.

They are all very hardy, and will grow in almoſt any ſoil or ſituation; they are propagated by parting their roots into ſmall heads, which in one year's time will ſpread and increaſe greatly. The beſt ſeaſon for this work is in the middle of october, ſoon after the flowers are paſt, or very early in the ſpring, that they may be well rooted before the droughts come on; otherwiſe their flowers will be few in number, and not near ſo fair, and by this means their roots will be weak; but if they are planted in october, you will ſave the trouble of watering them; their roots being ſurely fixed before the dry weather, they will need no other trouble than to clear them from weeds.

4. The Jeruſalem Artichoke is cultivated for the roots, which are by ſome people much eſteemed.

Theſe are propagated by planting the ſmaller roots, or the larger ones cut in pieces, obſerving to preſerve a bud to each ſeparate piece, either in the ſpring or autumn, allowing them a good diſtance, for their roots will greatly multiply; the autumn following, when their ſtems decay, the roots may be taken up for uſe. They ſhould be planted in ſome remote corner of the garden, for they are very unſightly while growing, their roots over-run every thing, and they cannot eaſily be deſtroyed.

[When deſired for a crop, the ſets ſhould be planted in an open part of the kitchen garden, in rows three feet or more aſunder, at leaſt eighteen inches diſtant from each other, and four or five inches deep. The beſt time for this is the latter end of march. A light ſoil ſuits them beſt. Some perſons cut the ſtalks half way down, at the end of july or the beginning of auguſt; becauſe they ſhade the ground too much, and from their great height are apt to be blown down. They may be taken up for preſent uſe in ſeptember, and the whole crop may be houſed in october. If kept in ſand in a dry place, they will continue the whole winter.

3. Heliconia hirſuta.
Lin. ſyſt. 245. *ſuppl.* 158.
Leaves rounded at the baſe, ſimply nerved, very ſmooth, inflorescence hirſute, ſpadix flexuoſe, nectary lanceolate, adnate.

DESCRIPTIONS, *&c.*

1. This is a very large herbaceous plant, from ten to twelve feet in height. Leaves oblong, narrower at both ends, entire, marked with parallel lines, erect, thick, and very ſmooth. Petioles the length of the leaves or more, round, thick, channelled above. Scape upright, the length of the petioles, round, thick, ſmooth. Spadix ſimple, upright. Common ſpathes ſeveral (eight to ten), rigid, cordate, embracing, from erect ſpreading, acuminate, diſtich, yelloviſh brown. Flowers in bundles concealed within each ſpathe: partial ſpathes membranaceous, whitiſh, the length of the flowers, which are diſtinct, ſubſeſſile, pale or greeniſh yellow. Corolla cohering at the baſe, unequal, curved and recurved, as it were two-lipped: the two upper petals lanceolate, acute, a little reflex at the tip, below the middle converging, and towards the baſe coaleſcent with the lower petal, whitiſh at the baſe: lower petal ſcarcely longer than the upper ones, lanceolate, concave, a little recurved, entire and acuminate at the tip, with its baſe embracing the nectary behind. Nectary two-leaved: the hinder leaflet of the ſame length with the corolla, broad-lanceolate, concave, above the middle ventricoſe underneath, trifid at the tip, the edges membranaceous, converging, bent in; it incloſes the filaments, and is filled with nectareous juice at the baſe; the leaflet in front is very minute, lanceolate, and faſtened to the anterior petal of the corolla. Filaments five, almoſt the length of the corolla, below the middle united into a tube open in front, glued to the hinder leaflet of the nectary. Anthers linear, acute, two-celled, yellow, frequently ſpiral. Germ three-cornered, attenuated at the baſe, retuſe at the tip, white. Style filiform, three-ſided. Stigma triangular, perforated, yellow, obtuſe, bent in. Capſule fleſhy, becoming black.

Native of the Weſt-Indies, in moiſt mountain woods, flowering in ſpring [a]. This beautiful plant grows wild in moſt of the cooler mountains of Jamaica, and thrives very luxuriantly in every rich and well-ſhaded gully among the woods.

The flowers have five perfect filaments ſhooting from the bottom of the real flower-leaf, and one imperfect filament from the nectarium. The berries are ſmall and ſucculent, and contain each three hard rugged ſeeds [b].

The younger Linneus, in the *Supplementum Plantarum*, has confounded three plants under the name of Heliconia Bihai; namely this, Strelitzia Reginæ, to which the ſpecific difference and deſcription there given belong, and Heliconia, or rather Strelitzia alba. —Heliconia Bihai was introduced into the royal garden at Kew in 1786, by Mr. Alexander Anderſon [c].

2. This plant bears a great reſemblance to Canna, and grows to the height of eight feet, with a ſimple ſmooth ſtem. Leaves ovate-lanceolate, entire, acute, very ſmooth, marked with parallel nerves: petioles ſheathing, ſmooth. Spadix ſimple. Spathes fewer (four to ſix), alternate, diſtich, ſomewhat remote, divaricated, two inches long, ſheathing at the baſe, acute, coloured blood-red, many-flowered. Flowers pedicelled, crowded, upright an inch long, fulvous; on round peduncles, half an inch long. Corolla three-ſided: the two upper petals erect, linear, acute, keeled, converging, glued to the nectary, the uppermoſt only trifid: the lower petal embracing the upper petals and nectary at the baſe, a little wider, keeled, venticroſe, browniſh green at the top. Hinder leaf of the nectary the length of the petals, lanceolate, concave, a little curved inwards, acuminate, entire, ſtriated, including the ſtamens: front leaf many times ſmaller, awl-ſhaped, concave, inſerted at the baſe into the lower petal. Filaments five, included within the hinder leaf of the nectary, free at the baſe. Anthers linear, two-celled, white. Germ three-ſided, truncate. Style ſlightly three-ſided, filiform. Stigma blunt, three-ſided, bent in, pubeſcent. Fruit three-cornered, truncate-depreſſed, ſcarlet at top. Native of Jamaica, in wet parts of the woods, on the higheſt mountains [a]: and in ſeveral parts of South America.

3. Stem and leaves very ſmooth. Spadix a ſpan long, hirſute, the joints thickened towards the next ſpathe. Spathes alternate, in two rows, lanceolate-awl-ſhaped, channelled, aſcending, the lower ones larger, with a hiſpid keel. Peduncles from nine to twelve, in the axils of the ſpathes, upright, round, very hirſute, ſhort, leafleſs, one-flowered, ſurrounded at the ſides both ways with awl ſhaped flat ſpathes or bractes, ſhorter than the flower, lying over each other in a ſingle row, within the cavity of the larger ſpathe. Germ obtuſe, hiſpid, obtuſely three-ſided. Corolla curved, two-petalled: upper petal complicated, hiſpid, bifid at the tip; lower broader, complicated, hiſpid, oblong, with a brown mark on the inſide at top. Nectary lanceolate, faſtened by the back to the upper petal. Stamens five, the length of the corolla. Style filiform. Stigma headed. In ſtature and leaves this reſembles the other ſpecies: the pericarp is the ſame with that of H. pſittacorum, only hiſpid.

Found in South America by Mutis [a].

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubulous, half-ovate, obliquely ſpreading, unequally five-cleft, coriaceous.
COR. *Petals* five, oblong, equal in breadth, fixed to the receptacle, longer than the calyx: *claws* long, with a tooth on each ſide at the baſe.
Nectary of five petal-ſhaped, lanceolate, very ſmall leaflets, covering the germ.
STAM. *Filaments* five, ten or more, very ſhort. *Anthers* oblong, lateral.
PIST. *Receptacle* filiform, very long, bowed back, bearing an ovate *germ* at the tip. *Style* ſubulate, longer than the germ. *Stigma* ſubquinquefid.
PER. *Capſules* five, often twiſted ſpirally, one-celled.
SEEDS very many, angular.
OBS. *In ſome ſpecies Jacquin and others have obſerved dodecandrous and polyandrous flowers, and ſtraight capſules. One ſpecies has no corolla.*

ESSENTIAL CHARACTER.

Pentagynous. Cal. one-leafed, oblique. *Petals* five. *Nect.* of five leaflets. *Capſ.* five, twiſted.

Dodecandrous, apetalous; leaves five-lobed, ſiliques divaricate.

DESCRIPTIONS, *&c.*

Shrubs or trees, native of the Eaſt or Weſt Indies, moſtly tomentoſe. Leaves alternate. Peduncles axillary, few-flowered.

1. This is an upright tree, about twelve feet in height, branching but little. The younger branches, peduncles and petioles are tomentoſe. Leaves acute, wrinkled, tomentoſe and whitiſh underneath, ſomewhat hairy on the upper ſurface, petioled, alternate, deciduous. Stipules awl-ſhaped. Peduncles many-flowered, terminating, thick. About the pedicels are large, depreſſed, green glands, uncertain in number, black when dried. The flowers have no ſcent. Calyx greeniſh yellow, with a white excavation, and lips ſometimes entire or ſcarcely divided. Petals whitiſh. Anthers yellow, having a tranſverſe groove where they are faſtened to the filaments, ſo that they ſeem to be two, and ſo large as to cover the nectary, germ and filaments [a]. Capſules growing on a very long, filiform common receptacle, of a ſuberoſe coriaceous ſubſtance, ſpiral, but always with the top ſtraight, on one ſide rounded, varicoſe, pubeſcent, on the other ſmooth, compreſſed to an edge, one-celled, one-valved, opening by the inner future. Seeds about fifty in each capſule, obovate, angular, ſmooth, of a brown cheſtnut colour [b]. The bark of the trunk and principal branches being eaſily peeled off and very tough is uſed inſtead of ropes.—Native of the iſland of Baru, in woods near the coaſt [c]: of the Weſt Indies. Cultivated in 1739 by Mr. Miller [d].

2. This alſo is a ſmall upright tree, about twelve feet high, branching but little. Younger branches, peduncles, calyxes and leaves tomentoſe. Leaves petioled, alternate, acute. Stipules in pairs, briſtle-ſhaped. Peduncles many-flowered, terminating, glandular. Calyx ſubcampanulate, unequally five-toothed. Petals white, obtuſe, reflex. Germ five-grooved, protruded beyond the flower on a very long pedicel, calycled with five peculiar leaflets. Filaments ten, upright, without the calyx of the germ, which is wholly covered by the tranſverſe oblong anthers. Capſules twiſted ſpirally into an ovate fruit; their tips make one revolution, and are covered with a cloſe nap, which is finally worn off by the weather before they fall. Seeds angular, ovate [e].

[a] Jacquin. [b] Gærtner. [c] Jacquin. [d] Hort. kew. [e] Jacquin.

This curious ſhrub, as Browne calls it, is very frequent in the low gravelly hills of Jamaica. It was cultivated in 1739, by Mr. Miller; and flowers here in june and july [f].

3. Stem ſhrubby, ſix feet high, upright, round, hairy; with diffuſed branches. Leaves pointed, tomentoſe, petioled, large. Peduncles many flowered, axillary. Calyx with a long, curved, hairy, coloured tube; border ſhort, four-cleft, the upper ſegment emarginate. Corolla duſky purple; petals turbinate-oblong, unequal, converging, with a toothlet above the baſe on each ſide; claws long, ſticking into the receptacle. Filaments ſhort, nearly equal, ending at bottom in a long, bent tube, placed on the receptacle: anthers ovate, two-celled, incumbent. Germ five-cornered, elevated on a long pedicel to the mouth of the ſtamineous tube: ſtyle filiform, ſlender, longer than the ſtamens: ſtigma thickiſh, very ſmall. Capſule oblong, five-valved, five-celled, blunt, rough with very many long, branching, harſh hairs; ſeeds bony.

In this and the fifth ſort the ſtamens are not Gynandrous, but rather Monadelphous; nor ought the pedicel ſupporting the germ to be looked upon as a receptacle, for it is entirely detached from the ſtamens. Native of Cochinchina, in woods.

4. This is a middling-ſized tree with ſpreading branches. Leaves quite entire, ſmooth, petioled. Flowers ſmall, moſtly terminating. Calyx none. Corolla greeniſh red. Anthers ſeſſile, two-celled, placed on the germ at the baſe. Germ five-cornered, pedunculed: ſtyle filiform, reflex: ſtigma orbiculate, five-parted. Siliques oblong, thick, ſcarlet, ſtraight above, convex underneath. Seeds few, ovate, ſmooth, brown, fleſhy, adhering to each valve by their proper pedicels. Native of Cochinchina, in woods [g].

5. Stem ſhrubby, five feet high, upright, branched. Leaves ſhining on the upper ſurface, veined underneath, tomentoſe, petioled, alternate. Flowers pale purple, on two-flowered, axillary peduncules. The calyx has a long, crooked tube, with a ſhort four-cleft border, the upper cleft emarginate. Petals rounded, ſmall, with a toothlet at the baſe. Filaments very ſhort, united into a long tube; with incumbent anthers. Style nearly equal to the ſtamens. Capſules united into one oblong-ovate, ſtraight, pedicelled fruit. Native of China about Canton [h].

6. Leaves alternate, acuminate, ſerrate; the floral leaves duſky purple. Calyxes hiſpid with branching briſtles. Petals the length of the calyx. Stamens five. Capſules twiſted, hairy.—Native of Surinam [i].

7. An upright tree, about twelve feet high. Leaves tomentoſe on both ſides. Flowers extremely fetid, generally coming out with the leaves, but ſometimes before them. Calyx browniſh yellow. Petals purple. It has ſo much the habit of the firſt ſort, that it can hardly be diſtinguiſhed from it, except in the flower and fruit.—Native of Carthagena in New Spain, in woods; flowering there in june and july [k].

8. This is a large tree, with ſpreading branches. Leaves quite entire, flat, ſmooth, petioled. Flowers in looſe panicles, moſtly terminating. Calyx none. Corolla of a reddiſh colour, and ſpreading very much. Anthers ſeſſile, more than twenty, adhering laterally to the middle of the germ. Style filiform, curved, with a convex, emarginate ſtigma. Siliques oblong, two-valved, red.—Native of Cochinchina, in woods [l].

9. This is an elegant tree, forty feet in height, with a large handſome head. Leaves plaited, ſmooth above, ſubvilloſe beneath, upwards of a foot in diameter, numerous; lobes ovate-roundiſh, acute, quite entire; on round petioles, nine inches in length. Flowers numerous, very fetid, dirty yellow with purple ſpots, without either petals or nectary; in large looſe panicles at the ends of the twigs. It is apparent that the filaments are the continuation of the bark or outer part of the receptacle; but that the germ ſprings from the pith of it.—Native of Carthagena, in woods, flowering from may and june to ſeptember [m].]

DESCRIPTIONS, *&c.*

1. This is a very large herbaceous plant, from ten to twelve feet in height. Leaves oblong, narrower at both ends, entire, marked with parallel lines, erect, thick, and very ſmooth. Petioles the length of the leaves or more, round, thick, channelled above. Scape upright, the length of the petioles, round, thick, ſmooth. Spadix ſimple, upright. Common ſpathes ſeveral (eight to ten), rigid, cordate, embracing, from erect ſpreading, acuminate, diſtich, yelloviſh brown. Flowers in bundles concealed within each ſpathe: partial ſpathes membranaceous, whitiſh, the length of the flowers, which are diſtinct, ſubſeſſile, pale or greeniſh yellow. Corolla cohering at the baſe, unequal, curved and recurved, as it were two-lipped: the two upper petals lanceolate, acute, a little reflex at the tip, below the middle converging, and towards the baſe coaleſcent with the lower petal, whitiſh at the baſe: lower petal ſcarcely longer than the upper ones, lanceolate, concave, a little recurved, entire and acuminate at the tip, with its baſe embracing the nectary behind. Nectary two-leaved: the hinder leaflet of the ſame length with the corolla, broad-lanceolate, concave, above the middle ventricoſe underneath, trifid at the tip, the edges membranaceous, converging, bent in; it incloſes the filaments, and is filled with nectareous juice at the baſe; the leaflet in front is very minute, lanceolate, and faſtened to the anterior petal of the corolla. Filaments five, almoſt the length of the corolla, below the middle united into a tube open in front, glued to the hinder leaflet of the nectary. Anthers linear, acute, two-celled, yellow, frequently ſpiral. Germ three-cornered, attenuated at the baſe, retuſe at the tip, white. Style filiform, three-ſided. Stigma triangular, perforated, yellow, obtuſe, bent in. Capſule fleſhy, becoming black.

Native of the Weſt-Indies, in moiſt mountain woods, flowering in ſpring [a]. This beautiful plant grows wild in moſt of the cooler mountains of Jamaica, and thrives very luxuriantly in every rich and well-ſhaded gully among the woods.

The flowers have five perfect filaments ſhooting from the bottom of the real flower-leaf, and one imperfect filament from the nectarium. The berries are ſmall and ſucculent, and contain each three hard rugged ſeeds [b].

The younger Linneus, in the *Supplementum Plantarum*, has confounded three plants under the name of Heliconia Bihai; namely this, Strelitzia Reginæ, to which the ſpecific difference and deſcription there given belong, and Heliconia, or rather Strelitzia alba. —Heliconia Bihai was introduced into the royal garden at Kew in 1786, by Mr. Alexander Anderſon [c].

2. This plant bears a great reſemblance to Canna, and grows to the height of eight feet, with a ſimple ſmooth ſtem. Leaves ovate-lanceolate, entire, acute, very ſmooth, marked with parallel nerves: petioles ſheathing, ſmooth. Spadix ſimple. Spathes fewer (four to ſix), alternate, diſtich, ſomewhat remote, divaricated, two inches long, ſheathing at the baſe, acute, coloured blood-red, many-flowered. Flowers pedicelled, crowded, upright an inch long, ſulvous; on round peduncles, half an inch long. Corolla three-ſided: the two upper petals erect, linear, acute, keeled, converging, glued to the nectary, the uppermoſt only trifid: the lower petal embracing the upper petals and nectary at the baſe, a little wider, keeled, venticroſe, browniſh green at the top. Hinder leaf of the nectary the length of the petals, lanceolate, concave, a little curved inwards, acuminate, entire, ſtriated, including the ſtamens: front leaf many times ſmaller, awl-ſhaped, concave, inſerted at the baſe into the lower petal. Filaments five, included within the hinder leaf of the nectary, free at the baſe. Anthers linear, two-celled, white. Germ three-ſided, truncate. Style ſlightly three-ſided, filiform. Stigma blunt, three-ſided, bent in, pubeſcent. Fruit three-cornered, truncate-depreſſed, ſcarlet at top. Native of Jamaica, in wet parts of the woods, on the higheſt mountains [a]: and in ſeveral parts of South America.

3. Stem and leaves very ſmooth. Spadix a ſpan long, hirſute, the joints thickened towards the next ſpathe. Spathes alternate, in two rows, lanceolate-awl-ſhaped, channelled, aſcending, the lower ones larger, with a hiſpid keel. Peduncles from nine to twelve, in the axils of the ſpathes, upright, round, very hirſute, ſhort, leafleſs, one-flowered, ſurrounded at the ſides both ways with awl ſhaped flat ſpathes or bractes, ſhorter than the flower, lying over each other in a ſingle row, within the cavity of the larger ſpathe. Germ obtuſe, hiſpid, obtuſely three-ſided. Corolla curved, two-petalled: upper petal complicated, hiſpid, bifid at the tip; lower broader, complicated, hiſpid, oblong, with a brown mark on the inſide at top. Nectary lanceolate, faſtened by the back to the upper petal. Stamens five, the length of the corolla. Style filiform. Stigma headed. In ſtature and leaves this reſembles the other ſpecies: the pericarp is the ſame with that of H. pſittacorum, only hiſpid.

Found in South America by Mutis [a].

DESCRIPTIONS, *&c.*

Shrubs or trees, native of the Eaſt or Weſt Indies, moſtly tomentoſe. Leaves alternate. Peduncles axillary, few-flowered.

1. This is an upright tree, about twelve feet in height, branching but little. The younger branches, peduncles and petioles are tomentoſe. Leaves acute, wrinkled, tomentoſe and whitiſh underneath, ſomewhat hairy on the upper ſurface, petioled, alternate, deciduous. Stipules awl-ſhaped. Peduncles many-flowered, terminating, thick. About the pedicels are large, depreſſed, green glands, uncertain in number, black when dried. The flowers have no ſcent. Calyx greeniſh yellow, with a white excavation, and lips ſometimes entire or ſcarcely divided. Petals whitiſh. Anthers yellow, having a tranſverſe groove where they are faſtened to the filaments, ſo that they ſeem to be two, and ſo large as to cover the nectary, germ and filaments [a]. Capſules growing on a very long, filiform common receptacle, of a ſuberoſe coriaceous ſubſtance, ſpiral, but always with the top ſtraight, on one ſide rounded, varicoſe, pubeſcent, on the other ſmooth, compreſſed to an edge, one-celled, one-valved, opening by the inner ſuture. Seeds about fifty in each capſule, obovate, angular, ſmooth, of a brown cheſtnut colour [b]. The bark of the trunk and principal branches being eaſily peeled off, and very tough is uſed inſtead of ropes.—Native of the iſland of Baru, in woods near the coaſt [c]: of the Weſt Indies. Cultivated in 1739 by Mr. Miller [d].

2. This alſo is a ſmall upright tree, about twelve feet high, branching but little. Younger branches, peduncles, calyxes and leaves tomentoſe. Leaves petioled, alternate, acute. Stipules in pairs, briſtle-ſhaped. Peduncles many-flowered, terminating, glandular. Calyx ſubcampanulate, unequally five-toothed. Petals white, obtuſe, reflex. Germ five-grooved, protruded beyond the flower on a very long pedicel, calycled with five peculiar leaflets. Filaments ten, upright, without the calyx of the germ, which is wholly covered by the tranſverſe oblong anthers. Capſules twiſted ſpirally into an ovate fruit; their tips make one revolution, and are covered with a cloſe nap, which is finally worn off by the weather before they fall. Seeds angular, ovate [e].

[a] Jacquin. [b] Gærtner. [c] Jacquin. [d] Hort. kew. [e] Jacquin.

This curious ſhrub, as Browne calls it, is very frequent in the low gravelly hills of Jamaica. It was cultivated in 1739, by Mr. Miller; and flowers here in june and july [f].

3. Stem ſhrubby, ſix feet high, upright, round, hairy; with diffuſed branches. Leaves pointed, tomentoſe, petioled, large. Peduncles many flowered, axillary. Calyx with a long, curved, hairy, coloured tube; border ſhort, four-cleft, the upper ſegment emarginate. Corolla duſky purple; petals turbinate-oblong, unequal, converging, with a toothlet above the baſe on each ſide; claws long, ſticking into the receptacle. Filaments ſhort, nearly equal, ending at bottom in a long, bent tube, placed on the receptacle: anthers ovate, two-celled, incumbent. Germ five-cornered, elevated on a long pedicel to the mouth of the ſtamineous tube: ſtyle filiform, ſlender, longer than the ſtamens: ſtigma thickiſh, very ſmall. Capſule oblong, five-valved, five-celled, blunt, rough with very many long, branching, harſh hairs; ſeeds bony.

In this and the fifth ſort the ſtamens are not Gynandrous, but rather Monadelphous; nor ought the pedicel ſupporting the germ to be looked upon as a receptacle, for it is entirely detached from the ſtamens. Native of Cochinchina, in woods.

4. This is a middling-ſized tree with ſpreading branches. Leaves quite entire, ſmooth, petioled. Flowers ſmall, moſtly terminating. Calyx none. Corolla greeniſh red. Anthers ſeſſile, two-celled, placed on the germ at the baſe. Germ five-cornered, pedunculed: ſtyle filiform, reflex: ſtigma orbiculate, five-parted. Siliques oblong, thick, ſcarlet, ſtraight above, convex underneath. Seeds few, ovate, ſmooth, brown, fleſhy, adhering to each valve by their proper pedicels. Native of Cochinchina, in woods [g].

5. Stem ſhrubby, five feet high, upright, branched. Leaves ſhining on the upper ſurface, veined underneath, tomentoſe, petioled, alternate. Flowers pale purple, on two-flowered, axillary peduncles. The calyx has a long, crooked tube, with a ſhort four-cleft border; the upper cleft emarginate. Petals rounded, ſmall, with a toothlet at the baſe. Filaments very ſhort, united into a long tube; with incumbent anthers. Style nearly equal to the ſtamens. Capſules united into one oblong-ovate, ſtraight, pedicelled fruit. Native of China about Canton [h].

6. Leaves alternate, acuminate, ſerrate; the floral leaves duſky purple. Calyxes hiſpid with branching briſtles. Petals the length of the calyx. Stamens five. Capſules twiſted, hairy.—Native of Surinam [i].

7. An upright tree, about twelve feet high. Leaves tomentoſe on both ſides. Flowers extremely fetid, generally coming out with the leaves, but ſometimes before them. Calyx browniſh yellow. Petals purple. It has ſo much the habit of the firſt ſort, that it can hardly be diſtinguiſhed from it, except in the flower and fruit.—Native of Carthagena in New Spain, in woods; flowering there in june and july [k].

8. This is a large tree, with ſpreading branches. Leaves quite entire, flat, ſmooth, petioled. Flowers in looſe panicles, moſtly terminating. Calyx none. Corolla of a reddiſh colour, and ſpreading very much. Anthers ſeſſile, more than twenty, adhering laterally to the middle of the germ. Style filiform, curved; with a convex, emarginate ſtigma. Siliques oblong, two-valved, red.—Native of Cochinchina, in woods [l].

9. This is an elegant tree, forty feet in height, with a large handſome head. Leaves plaited, ſmooth above, ſubvilloſe beneath, upwards of a foot in diameter, numerous; lobes ovate-roundiſh, acute, quite entire; on round petioles, nine inches in length. Flowers numerous, very fetid, dirty yellow with purple ſpots, without either petals or nectary; in large looſe panicles at the ends of the twigs. It is apparent that the filaments are the continuation of the bark or outer part of the receptacle; but that the germ ſprings from the pith of it.—Native of Carthagena, in woods, flowering from may and june to ſeptember [m].]

[f] Hort. kew. [g] Loureiro. [h] Ibid. [i] Linn. mant. [k] Jacquin. [l] Loureiro. [m] Jacquin.

PROPAGATION AND CULTURE.

These plants are propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up strong enough to remove, they should be each planted in a separate small pot, filled with light earth, and plunged into a moderate hot-bed of tan, observing to shade them from the sun till they have taken new root; then they should be treated in the same way as other tender plants from hot countries, raising the glasses every day in proportion to the weather, that the plants may enjoy fresh air, which will strengthen them, and prevent their drawing up weak. In the summer the plants may remain under the frames, if there is sufficient height for them to grow; but in autumn they must be plunged into the tan-bed in the stove, where they should always remain, being careful to shift them into larger pots when they require it, and not give them too much wet in the winter; but in summer they should have a large share of air in warm weather, and require to be often refreshed with water: the second year from the seeds these plants have often flowered in the Chelsea garden, and the seeds have some years ripened there, but the plants will live several years with proper management.

HELIOCARPUS. *(From* Ηλιος, *the sun, and* Καρπος, *fruit, which being surrounded by rays, resembles the sun, as it is commonly represented.)*

GENERIC CHARACTER.

CAL. *Perianth* four-leaved, coloured: *leaflets* linear, long, broadish, spreading, deciduous.

COR. *Petals* four, linear, much shorter than the calyx, narrower.

STAM. *Filaments* sixteen, awl-shaped, almost the length of the calyx. *Anthers* twin, linear, incumbent.

PIST. *Germ* roundish. *Styles* two, simple, upright, length of the stamens. *Stigmas* acute, distant.

PER. *Capsule* turbinate-ovate, peduncled, compressed, surrounded perpendicularly on both sides with rays pinnately branched; two-celled, two-valved; with the partition contrary.

SEEDS solitary, subovate.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* four-petalled. *Styles* simple. *Caps.* two-celled, compressed, longitudinally radiated on both sides: *(superior, club-shaped, surrounded with filiform feathered rays, G.)*

SPECIES.

1. Heliocarpus americana. *American Heliocarpus.*
Lin. spec. 643. *Reich.* 2. 430. *hort. cliff.* 211. *t.* 16. *Trew Ehret. t.* 45. *Gærtn. fruct.* 225.

DESCRIPTION, &c.

It rises with a thick, soft, woody stalk, from fifteen to eighteen feet high, sending out several lateral branches towards the top. Leaves heart-shaped, full of veins, serrate, ending in acute points, alternate, on oblique petioles three inches long. The flowers are produced at the ends of the shoots, in branching clusters, and are of a yellowish green colour.

[Capsule pubescent, surrounded with feathered bifid rays; having a single seed in each cell, keeled on one side, flattish on the other, with a slight groove at bottom, of a brownish bay colour, fastened to a small tubercle in the middle of the partition *.

This tree is very nearly allied to Triumfetta. The calyx is four-leaved, and the corolla four-petalled; both are of a whitish or herbaceous colour, and have the appearance of a corolla with eight petals.]

It was discovered by Dr. Houstoun (before 1733), growing naturally about La Vera Cruz in New Spain, whence he sent the seeds to England; they succeeded, produced flowers, and ripe seeds during several years in the Chelsea garden.

PROPAGATION AND CULTURE.

This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a separate small pot filled with light kitchen-garden earth, and plunged into a hot-bed, treating them in the same way as other tender plants, which will not bear the open air in this country at any season of the year; and while the plants are young, they require to be plunged into the tan-bed, but after they have acquired strength, they will thrive in the dry stove. In winter they should have but little water, and must be kept warm; but in summer they should have plenty of fresh air in mild weather, and must be frequently refreshed with water. With this management the plants will flower the third year, and produce good seeds, but may be preserved several years with proper care.

I have sowed the seeds of this plant which had been kept ten years, and came up as well as if it had been saved the former year; though from the appearance of the seeds, it seems as unlikely to grow after the first year as any which I know.

HELIOPHILA. *(From* Ηλιος, *the sun, and* φιλος *a friend. These plants being fond of sun-shine.)*

Lin. gen. n. 816. *Reich.* 880. *Schreb.* 1092. *Juss.* 238.—*auctore Nic. Burmanno, in nov. act. upf.* 1. 94. *t.* 7.—*Chamira Thunb. nov. gen.* 48.

Class. 15. 2. Tetradynamia Siliquosa.

Nat. order of *Siliquosæ.—Cruciformes, Cruciferæ,* Juss.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved: *leaflets* spreading, oblong, concave, membranaceous at the edge, deciduous: the two outer ones bladdery at the base.

COR. four-petalled, cruciform: *petals* roundish, flat, sessile.—*Nectaries* two from the receptacle, bowed back towards the bladder of the calyx.

STAM. *Filaments* six, awl-shaped, erect, the length of the calyx, two opposite a little shorter. *Anthers* oblong, erect.

PIST. *Germ* cylindric. *Style* shorter than the germ. *Stigma* blunt.

PER. *Silique* columnar, somewhat toruloſe, mucronate, two-celled, two-valved.

SEEDS several.

ESSENTIAL CHARACTER.

Nectaries two, bowed back towards the bladder of the calyx.

SPECIES.

Leaves palmate-pinnatifid villoſe: pinnas linear.
10. Heliophila pinnata.
Lin. ſyſt. 599. *ſuppl.* 297.
Leaves trifid and pinnate; leaflets linear: ſiliques neck-lace-ſhaped upright.

DESCRIPTIONS, *&c.*

Theſe are all natives of the Cape of Good Hope.]

1. Stalk erect, four or five inches high, ſending out two or three ſide branches. [Leaves rough with hairs on the upper ſurface, ſmooth underneath. The bladders or bunches at the baſe of the calyxes are diaphanous.] The flowers grow in a looſe terminating bunch, and have no ſcent. [The corolla reſembles that of Flax or Anagallis Monelli: is blue, and cloſes at night[a].] The pods are near three inches long, taper, and contain a double row of flat ſeeds.

[Cultivated by Mr. Miller in 1768[b].

2. This is a ſmooth plant[c].] It grows about the ſame height with the other, but branches more. The flowers are like thoſe of the foregoing.

[Cultivated by Mr. Miller in 1768.—It flowers from june to october, and is ſhrubby[d]. According to Mr. Miller theſe are both annual plants.

3. Found at the Cape of Good Hope with moſt of the other ſorts by Thunberg.

4. Shrubby. Flowering in may and auguſt. Introduced in 1774, by Mr. Francis Maſſon[e].

5. Annual. Stem half a foot high, herbaceous, ruſty; branches upright, ſhorter. Racemes horizontal, on horizontal pedicels. Calyx expanding very much; leaflets alternate with the petals, linear, channelled, blunt. Petals ſpreading as the calyx does, but near three times as large, pale, ſtreaked. Silique awl-ſhaped, ſtiff, very ſmooth and even[f]. It flowers in july and auguſt. Introduced in 1786, by John Sibthorp, M. D.[g]

6. Annual. A ſpan high, upright, branched, the ſtature of *Arabis thaliana*. Stem-leaves linear, ſmooth and even. Siliques patulous, peduncled; the joints ſeparate, orbicular, compreſſed.

7. Shrubby, having the appearance of Broom, upright, ſparingly branched, ſtiff. Leaves alternate, remote, ſmooth and even. Racemes terminating, long, ſimple; the flowers diſtant. Calyx very ſhort, ovate, cloſed, blunt, ſomewhat ſcarioſe about the edge. Petals obovate, the ſame ſize as in the Cabbage, yellow, veiny; the claws longer than the calyx. Stamens the length of the calyx. Germ ovate. Silique the length of the petals, columnar with four blunt angles. It varies with red corollas.—It is doubtful whether this be a natural ſpecies of this genus.

8. Stem brittle, branched, herbaceous. Leaves ſomewhat angular. Calyx with the leaflets cloſed, linear, gaping at the baſe, deciduous; two oppoſite ones with ſomething like a ſpur at the baſe; the protuberance half the length of the leaflets. Petals oblique. Anthers reflex at the tip. Germ ovate-oblong. Valves of the ſilique convex, gibbous, juicy: partition globular, fleſhy, ſtanding out beyond the valves. Seeds three or four, roundiſh[h].

It is thus deſcribed by Thunberg, under the name of Chamira cornuta.

The whole plant is ſucculent, weak, ſmooth. Root fibrous, annual. Stem one or more procumbent or ſubſcandent, ſomewhat angular at bottom, round at top, ſmooth. Branches alternate, gradually growing thinner to the end. Leaves alternate, petioled, cordate-roundiſh, acuminate, tooth-angled; the lower larger; the upper regularly leſs, nerved. Petioles ſemicolumnar, channelled above, ſhorter than the leaf, ſpreading. Flowers alternate, very remote, but towards the end nearer, peduncled. The flowering peduncles erect, a line in length, bearing one flower: fruit peduncles reflected.

9. The ſtem thickens very much upwards, which gives this plant a ſingular appearance.

10. This reſembles the ſixth ſpecies very much, but it has branched or pinnate leaves[i].]

PROPAGATION AND CULTURE.

The ſeeds may be ſown in the ſpring on a ſouth border, and when the plants come up, if they are thinned and kept clean from weeds, it is all the culture they require.

HELIOTROPE. See *Heliotropium*.

HELIOTROPII FLORE. See *Tournefortia*.

HELIOTROPIUM. (*From* Ηλιος, *the Sun, and* τρεπω, *to turn. Becauſe the leaves or flower were ſuppoſed to turn with the ſun. Hence the French name Turnſole. Or becauſe it flowered about the ſummer ſolſtice.*)

Leaves lanceolate obtuſe half-ſtem-cloſping, ſpikes branching, ſtem ſhrubby.]

DESCRIPTION, &c.

1. This riſes with a ſhrubby ſtalk from two to three feet high, dividing into many ſmall branches. Leaves three inches long, and an inch and half broad in the middle, hairy, greatly veined, and aſh-coloured on their under ſide, on ſhort foot-ſtalks. The flowers are produced at the ends of the branches in ſhort reflex ſpikes, growing in cluſters: the pedunckes divide into two or three, and theſe again into ſmaller ones, each ſuſtaining a ſpikelet of pale blue flowers, which have a ſtrong ſweet odour, [of a very particular nature, ſomewhat reſembling that of bitter Almonds.

Stems rough with hairs, with branches longer at bottom. Leaves elliptic or ovate-oblong, marked with lines, wrinkled, pubeſcent and ſcabrous. Peduncles towards their extremities rough with hairs, bifid or dichotomous. Spikes directed one way, bowed back [a]. There are uſually three or four in number, coming out from different points, about an inch in length. The corolla has a very ſhort globular tube, ſpreading into a wide border. Seeds almoſt globular, diſtinct, fixed to a cylindric prominence, in the middle [b].]

It grows naturally in Peru, whence the ſeeds were ſent by the younger Juſſieu to the royal garden at Paris. Mr. Miller had the ſeeds (about the year 1757) from the curious garden of the Duc d'Ayen at St. Germain's. It flowers here great part of the year, and thoſe flowers which come out in ſummer, are ſucceeded by ripe ſeeds in autumn.

2. [Stem herbaceous, a foot and half or two feet high, round, ſcabrous, hirſute, ſubdivided. Leaves cordate-ſpatulate, ovate, ſlightly ſerrate, wrinkled, nerved, hairy, ſoftiſh: on pretty long petioles, two inches and a half long, and one and a half broad in the middle. [Spikes terminating, ſingle or ſolitary, ſometimes but very ſeldom double; ſometimes alſo from the ſides of the branches, reflex only at the end. Flowers ſeſſile, pointing one way, approximating in a double row, ſmall, blue: tube very long, cylindric, not globular, as in the others, border ſcarcely half-five-cleft, ſegments equal, blunt; throat five-rayed, orange-coloured, cloſed. Germs in connate pairs. Seeds one-celled; two, three, or four of unequal ſizes, and if more than two, the reſt are abortive: the fertile ones are ovate, acuminate, ſwelling a little on the outſide, covered with a juicy bark, and ſlightly connected at the baſe [c].]

Native of the Weſt Indies, and Cochinchina. Annual, or biennial. It flowers in july and auguſt; the ſeeds ripen in ſeptember and october. [Cultivated in 1713 [d].

The variety, which Mr. Miller makes a diſtinct ſpecies] is a ſmaller plant, ſeldom above two feet high; the leaves are an inch and half long, and about half an inch broad: the ſpikes of flowers are very ſlender, and not more than two inches long; the flowers are ſmall, and of a light blue colour.

[3. Nearly allied to the foregoing. Stem erect, pubeſcent, a foot high. Moſt of the leaves oppoſite, except thoſe in the middle of the ſtem, which are alternate, petioled, lucid, acute. Peduncles oppoſite to the leaves, or from the diviſions of the ſtem, longer than the leaves, erect; each having two recurved, imbricate ſpikes. Corolla minute, pervious, white with a yellow baſe [e]. The ſeeds are contained in a roundiſh capſule, with four cells, and one ſeed in each [f].

Annual. Native of the Weſt Indies. It flowers in

[a] Linn. ſyſt. [b] Murr. prodr. [c] Murr. prodr. and Swartz. [d] Hort. kew. [e] Linn. mant. [f] Murr. prodr.

july and auguſt. Cultivated in 1732, by James Sherard, M. D. [s].

The ſeeds came up in earth ſent with Barbadoes plants to Mr. Newport a merchant in London, and which he gave to the Eltham garden [b].

4. Native of the Caribee iſlands [t].

5. This riſes about ſeven or eight inches high, dividing into two or three branches. Leaves rough, two inches long and one inch broad in the middle, of a light green, ſtanding upon pretty long foot-ſtalks alternately: the flowers are produced at the ends of the branches in double ſpikes, joined at the bottom, about an inch long, turning backward. Flowers white, appearing in june and july.

[Seeds four, naked, equal, ovate, convex on the outſide, with a ſmooth, juicy bark; on the inſide, where they are joined divided into two planes by a prominent angle without bark [k].—Cultivated in 1562, by William Turner, M. D. [l].

β. Flowers larger and ſweet [m].

6. Burman has figured this as a variety of the foregoing ſpecies; it is eaſily diſtinguiſhed from it however, by the ſtrigoſeneſs of the whole plant, by the plaits and ſmallneſs of the leaves, by the ſhortneſs of the petioles, and by the ſpikes not being conjugate, though they are frequently two together. The calyxes are by no means imbricate, but larger and diſtinct, involving the ſeeds even when they are ripe.—Native of Malabar [n].

7. This is ſmaller than the common ſort (n. 5.), with more ſlender branches, ſomewhat lanuginous, and proſtrate. The root ſmall and annual. Flowers white. Seeds uſually one or two only, the reſt being abortive: larger and more oblong than in the common ſort, brown, and covered with a bark [o].—Native of the Cape of Good Hope; flowering in june and july. Cultivated in 1640 [p].

8. Stem ſhrubby, two feet high (Miller ſays, one foot and a half, and Browne that it ſeldom riſes above five or ſix inches) very much branched: branches ſtiff, ſcabrous and aſh-coloured. Leaves on ſhort petioles, alternate, ſmall,] ſcarcely one inch long, and one third of an inch broad in the middle, [acute, rigid, rolled back at the edge, recurved at the tip, hirſute, and hiſpid on the upper ſurface, hirſute and hoary on the lower [q]. Spikes always ſingle, and not much bent [r], ſmall and ſlender. Flowers terminating, on ſhort pedicels, pointing one way; on ſhort, axillary, hiſpid peduncles. Segments of the calyx upright, ſtiff. Corolla white; border five-cornered; throat cloſed, pale, having five rays from the centre to the angles of the border. Filaments from the middle of the tube: anthers converging and cohering at the tip. Germ ovate; ſtyle ſhort, ſubulate; ſtigma capitate. Capſule roundiſh containing two hemiſpherical ſeeds [s].—Native of the Weſt Indies, near the ſea ſhore. Cultivated by Mr. Miller, in 1759.

9. Root annual. Stem round, very ſmooth, with a glaucous gloom on it.] The branches trail on the ground, and grow a foot (or ſixteen inches) in length. Leaves ſomewhat blunt, quite entire, upright, on very ſhort petioles, ſome alternate others oppoſite. [Browne ſays, that it is eaſily diſtinguiſhed by its whitiſh ſmooth narrow leaves. Spikes in pairs on a common peduncle and recurved. Corolla white, with a yellow bale, and an open throat [t].—The fruit is an ovate-globular berry, containing four nuts, drying up as it grows ripe, and diviſible into four parts: fleſh thin, becoming the membranaceous bark of the nuts: which are cruſtaceous, hard, moderately thick, convex on one ſide, angular on the other, and in the middle of the angle having a deep little pit; they are imperforate and one-celled. Seeds ſolitary, ovate-oblong, having a very ſhort beak, convex on one ſide, ſlightly concave on the other, pale [u].

Native of the Weſt Indies; flowering here in june and july. Cultivated in 1759 by Mr. Miller [w].

[w] Hort. kew.

10. A ſmall procumbent creeping plant. Leaves alternate. Flowers ſubſeſſile, alternate, ſolitary, ſcattered among the leaves.

Annual.—Native of Aſia [x].

11. This is an upright ſhrubby plant, commonly two feet high, ſometimes but ſeldom riſing to the height of ſix feet. Branches round, little divided, the older ones blackiſh, the younger ſcarred at bottom where leaves have grown, all together forming a convex, white, handſome head, viſible far off at ſea. Leaves wedge-linear, veinleſs, thick, tomentoſe on both ſides, glaucous, ſeſſile, numerous, crowded at the ends of the branches. Common peduncles round, tomentoſe, erect, a little longer than the leaves, terminating, few on each branch, bifid or trifid at top; ſingle pedicels ſpring from the diviſions, and form a ſpike directed one way, frequently bifid itſelf, but ſometimes ſimple. Flowers ſmall, with the calyxes of all ſo connected, that no one can be taken out without tearing the next. Corolla white [y].

Native of Cuba, Jamaica, Barbadoes, St. Euſtatia, &c. on the coaſt. Cultivated by Mr. Miller before 1759.

12. This ſpecies bears the appearance of a Sherardia. The root is ſimple and fuſiform. Stems ſubdichotomouſly branched and ſtrigoſe. Leaves alternate, moſtly oblique, on the uppermoſt branches ſometimes oppoſite, quite entire. Flowers terminating, ſmall, white, fenced with leaves. Calyxes nearly equal, hiſpid. Seeds four, roundiſh, ſmooth, only a little wrinkled at the tip.—Native of the Eaſt Indies. Sent by Koenig.

13. Root woody. Stems branched, hiſpid. Leaves alternate and ſcattered, ſharp, reſembling thoſe of Teucrium Marum, only ſmaller. Spikes copious, without order, not compact, with bractes of the ſame ſhape with the leaves. Flowers white, hirſute on the outſide, as are alſo the calyxes.

14. Root ſimple, fuſiform. Stems erect and proſtrate, hiſpid. Leaves alternate and oppoſite. Spikes lateral and terminating. Calyx unequal, hiſpid. Flowers ſmall, white.—Both natives of the Eaſt Indies, and ſent by Koenig [z]. This alſo is a native of Arabia; the Arabian plant differing from the Indian, according to Vahl, only in having the twigs, leaves and ſeeds more cloſely villoſe and ſilky.]

15. This ſort riſes with a ſhrubby ſtalk ſix or ſeven feet high: the young branches are cloſely covered with a white down, and the leaves on theſe are very hoary and entire, but thoſe on the older branches are greener, and ſome of them are notched on their edges; at each joint of the ſtalks come out two ſhort branches oppoſite, with ſmall hoary leaves placed oppoſite: theſe, when bruiſed, emit a ſtrong odour, which to ſome perſons is very diſagreeable, but others are pleaſed with it. The plants rarely flower in England, for in near forty years which I have cultivated them, I have but once ſeen them in flower. The flowers are white, collected in roundiſh heads, which turn backward, and ſit cloſe to the branches; the leaves continue all the year.

16. This ſort grows naturally in the Canary Iſlands. It riſes with a woody ſtalk three or four feet high, dividing into many branches, with leaves upon long foot-ſtalks; hairy, and of an aſh colour on their under ſide; the flowers are produced from the ſide of the branches on pretty long peduncles, each ſuſtaining four ſhort roundiſh ſpikes or heads, which divide by pairs, and ſpread from each other. The flowers are white and appear in june and july, but are not ſucceeded by ſeeds in England. The leaves of this plant, when bruiſed, emit an agreeable odour, for which it is by ſome perſons much eſteemed; the gardeners have given it the title of Madam Maintenon, but for what reaſon I know not.

17. This ſort was ſent me from Carthegena in New Spain, where it grows naturally on the ſandy ſhores. This is an annual plant, with trailing ſtalks which grows ſix or ſeven inches long, with ſmall leaves. The flowers are produced at the end of th

[x] Linn. ſpec. [y] Jacquin. [z] Retzius. [a] Vahl. Icones

branches, in ſingle ſhort ſpikes, which are reflexed; they are ſmall and white, making little appearance.

18. This ſort was ſent me by the late Dr. Houſtoun from La Vera Cruz, where he found it growing in plenty; this riſes with a ſhrubby ſtalk three feet high, dividing into ſlender branches, which are cloſely garniſhed with leaves, placed without order. The flowers are produced at the end of the branches, in double ſpikes, which are ſlender, ſhort and ſtraight, not recurved as the other ſpecies. The flowers are ſmall and white, and the plant is perennial.

[The fifteenth was cultivated by Mr. Miller about the year 1728 or ſoon after; and the eighteenth before 1733.

19. Stem herbaceous, annual, one foot high, ſomewhat erect, diffuſed, whitiſh, obtuſely four cornered, with purple joints. Leaves crenate. Flowers red, in long cloſe ſpikes; corolla ſomewhat bell-ſhaped. Stamens four, nearly equal to the corolla.—In the gardens of Cochinchina[b].

20. Stem woody, hairy, ſubdichotomous, round. Branches a ſpan long and more. Leaves alternate, narrow lanceolate; the lower ones narrowing into a very ſhort petiole; the upper ones ſeſſile, half an inch long, bluntiſh, wrinkled, hiſpid eſpecially towards the edge; hairs preſſed cloſe, placed on minute tubercles. Spikes lateral and terminating, an inch long, compact. Calyx hairy, five-cleft; with linear, blunt ſegments. Corolla hairy on the outſide, longer than the calyx; tube widening in the middle, contracting at top; throat pervious; limb five-cleft; with a tooth-like plait between the clefts. Stigma conical, with two teeth at the tip, ſurrounded at the baſe with a ring.

21. Stem ſhrubby, round, dichotomous, the ſize of a pigeon's quill. Branches ſlender, a ſpan long, villoſe, tomentoſe above. Leaves half an inch long, acute, ſoft eſpecially underneath, marked with three lines on both ſides. Spikes lateral and terminating. Bractes linear, acute. Calyx villoſe, with lanceolate ſegments. Corolla ſmooth, longer than the calyx; tube widening at top; throat pervious; a tooth between the ſegments of the limb. Style filiform. Stigma conical, acute, quite entire, villoſe at the tip. Seeds villoſe. Diſtinguiſhed from the foregoing by the form and hairineſs of the leaves, with the edge not at all waved; by the preſence of bractes; by the ſmoothneſs of the corolla: and by the ſtigma being quite entire.—They are both natives of Arabia, and by their habit, inflorescence and tooth between the ſegments of the corolla, belong to this genus.

22. Branches round, hoary with ſmall hairs preſſed cloſe. Leaves on very ſhort petioles, ſharp, rugged on the upper ſurface with white dots, on which hairs are placed, the edge rolled back above, but flat towards the baſe. Peduncle terminating, erect, bifid; the lateral ones ſometimes with ſimple ſpikes. Bracte linear, the length of the calyx; which is hairy. Corolla white, larger than in the other ſorts.

Perhaps only a variety of H. fruticoſum, with broader leaves.—Native of the Weſt Indies.

23. Stem erect, herbaceous, ſimple, only branching a little at the baſe, a foot high, the ſize of a gooſe quill, villoſe. Leaves petioled, at the root many; on the ſtem few, alternate; ternate, or pinnate with two pairs and an odd leaflet. Leaflets alternate, lanceolate, acute, ſoftly villoſe, greeniſh aſh-coloured, quite entire, flat, nerved; the end-one two inches long, uſually ſhorter on one ſide at the baſe: the lateral ones ſubſeſſile, much ſmaller. Peduncles axillary and terminating. Spikes undivided, very hairy. Flowers crowded. Found by Thouin at the ſtraits of Magellan.

24. Branches hairy. Leaves alternate, two inches long, obſcurely repand, a little narrowed towards the baſe, greeniſh hoary on both ſides with minute hairs preſſed cloſe, ſmooth along the nerves, but not marked with lines, veinleſs, nerved underneath. From the axils there are rudiments of branchlets. Peduncle terminating, hairy, twice or thrice dichotomous at top. Tube of the corolla twice as long as the calyx, with few villoſe hairs ſcattered over it. It has the habit of *peruvianum*, and was found in Braſil by Thouin[c].]

[b] Loureiro. [c] Vahl.

PROPAGATION AND CULTURE.

1. May be propagated either by ſeeds or cuttings. The ſeeds may be ſown upon a moderate hot-bed in the ſpring: when the plants are fit to remove, tranſplant them into ſmall pots filled with light earth, plunge them into a hot-bed, and ſhade them till they have taken new root; then inure them by degrees to the air, into which remove them in ſummer, placing them in a ſheltered ſituation; in autumn houſe them in a good greenhouſe, where they will flower great part of winter.—If the cuttings be put into pots filled with light earth, during any of the ſummer months, and plunged into a moderate hot-bed, they will take root freely, but theſe do not make ſo good plants as thoſe raiſed from ſeed.

[A ſtove is moſt congenial to this plant in winter. A pure atmoſphere is eſſential to its exiſtence. In hot weather it muſt be well ſupplied with water, and in winter it muſt be carefully guarded againſt froſt; ſo fatal to moſt of the natives of Peru[a].]

2, 3, 9. Sow the ſeeds on a hot-bed in the ſpring, and when the plants are fit to remove, tranſplant them on another hot-bed, to bring them forward, treating them in the ſame way as the Balſamine, and other tender annual plants; in june take them up with balls of earth, and plant them in the borders of the flower garden, where they will flower, and in warm ſeaſons produce ripe ſeeds.

5, 7. Theſe are annual ſorts, which ſucceed better from ſeeds which ſcatter in the autumn, or are ſown at that ſeaſon, than in the ſpring: for when they are ſown in the ſpring, they ſeldom come up the ſame ſeaſon; but if the ſeeds be ſuffered to ſhed, theſe plants will maintain themſelves, without any other culture, but keeping them clean from weeds, and thinning them where they are too cloſe.

8, 17, 18. Theſe are propagated by ſeeds, *but* the difficulty of getting them freſh from America, and the uncertainty of their growing unleſs they are *ſown* abroad, and brought over in earth, has rendered them rare in Europe. Being plants of little beauty, requiring a ſtove, with a peculiar ſoil and management, they have been cultivated merely for variety in botanic gardens.

11. This is propagated by ſeeds, which muſt be procured from the places where it naturally grows, for it never produces any in Europe; theſe ſeeds ſhould be ſown in a tub of earth in the country, for when the dried ſeeds come over they ſeldom grow; and if they do, it is not before the ſecond year; and from ſeveral parcels of the ſeeds which I have received from the Weſt Indies, I have not raiſed more than two plants, and theſe came up from the ſeeds which had been ſown more than a year; ſo that if the ſeeds are ſown as ſoon as they are ripe in a tub of earth, when they arrive in England, the tub ſhould be plunged into a hot-bed of tanners bark, which will bring up the plants; and when theſe are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with earth, compoſed of ſand and light undunged earth, with a little lime rubbiſh well mixed together, then plunged into a hot-bed of tanners bark, and ſhaded until they have taken new root; after which, they muſt be treated as other tender exotic plants, always keeping them in the tan-bed in the ſtove, giving them but little water eſpecially during the winter ſeaſon.

15, 16. Theſe are too tender to live through the winter in the open air in this country, ſo muſt be kept in a green-houſe during that ſeaſon; but only requiring to be ſcreened from froſt, they may be placed with myrtles and the other hardy green-houſe plants, where they may have a large ſhare of air in mild weather, and be treated in the ſame way; they are eaſily propagated by cuttings during any of the ſummer months, which, if planted in a ſhady border and duly ſupplied with water, will take root in five or ſix weeks; then they may be potted, and placed in a ſhady ſituation till they have taken new root, after which they may be treated as the old plants.

[The other ſorts have not yet been introduced into our gardens.

GENERIC CHARACTER.

CAL. none—unless the corolla, which in some species is permanent, be considered as such.

COR. *Petals* five, roundish, blunt, large.

Nectaries several, very short, placed in a ring, one-leafed, tubular, narrower at bottom: *mouth* two-lipped, upright, emarginate, the inner lip shortest.

STAM. *Filaments* numerous, subulate. *Anthers*, compressed, narrower at bottom, upright.

PIST. *Germs* about six, compressed. *Styles* subulate. *Stigmas* thickish. (Pist. five or more, permanent, *G.*)

PER. *Capsules* (leguminous, beaked, *G.*) compressed, two-keeled: the lower keel shorter; the upper convex, gaping.

SEEDS several, round, fixed to the future.

OBS. H. hyemalis *drops its petals; the other sorts retain them, and they become green. The number of pistils varies much.*

ESSENTIAL CHARACTER.

Cal. none. *Pet.* five, or more (or *Calyx* five-leaved, *Cor.* none.) *Nect.* two-lipped, tubular. *Capf.* many-seeded.

Scape one flowered, leaves ternate.

DESCRIPTIONS, &c.

The Hellebores are all hardy herbaceous perennials, with compound leaves, digitate, pedate, palmate or ternate. The flowers have only a single cover, which is called a corolla by Linneus, by others a calyx; they grow either several together at the ends of the stalk and its subdivisions with a single bracte to each pedicel; or single on a scape, naked or with a leaf for an involucre. They appear very early in the spring, and some of them even in winter.

1. Root tuberous, transverse, with many dependent fibres, putting up several naked stems or scapes, simple smooth, round, from an inch or two to four inches in height, terminated by a single leaf, spreading out horizontally in a circle, divided into five parts almost to the base, and the parts simple or divided into two, three or four lobes. In the bosom of this sits one large upright, yellow flower; the petals ovate, marked with lines, converging a little, deciduous, usually six in number (six to eight): pistils six (four to six), and stamens about thirty *.

Native of Lombardy and other parts of Italy; Austria, Silesia, Switzerland; in mountainous situations. It flowers with us from january to march; and was cultivated by Gerarde in 1596. In his herbal published the year following, he informs us, that we had then great quantities of it in our London gardens: and therefore it is probable that it was known among us much earlier than 1596. He calls it Winter-Wolf's bane, or small yellow Wolf's-bane. According to Parkinson, most herbarists called it Winter Wolf's-bane; but some Yellow Aconite. The name of *Winter Aconite* has now generally obtained.

2. Stem a hand height, upright, round, smooth, leafy at top, sustaining one or two flowers. Root

* Linn. mant. Haller, Krocker.

leaves on long petioles; ſtem-leaves ſubſeſſile, embracing; ſerrate, ſmooth, paler underneath, variouſly gaſhed. Flowers axillary, ſolitary, peduncled, upright, yellow: petals roundiſh, ſpreading, marked with lines: nectaries numerous, curved, half the length only of the petals: filaments very ſhort; anthers linear, yellow. It is very nearly related to the foregoing ſpecies, but handſomer: it differs alſo in having the leaves more compound and gaſhed; the flower peduncled; the petals broader and more ſpreading. Tournefort firſt brought us acquainted with it from Cappadocia'.

3. Roots tranſverſe, externally rough and knotted, with many dependent fibres, and ſome large roots ſtriking down. Scapes from ſix inches to near a foot in length, round, upright, variegated with red, riſing from a ſheath, and terminated uſually with one flower, ſometimes two, and very rarely three. Corolla very large, generally white at firſt, but frequently with a tint of red growing deeper with age, but finally becoming green: nectaries (eight or ten to twelve or thirteen) greeniſh yellow, the upper lip longeſt and ſlightly emarginate, the lower finely notched. Stamens more than ſeventy. Germs from four to eight. Each flower has a bracted leaf or two, ſupplying the place of the calyx. Leaves only from the root, deep and dark green, on long petioles; leaflets (five to eight or nine) ovate-lanceolate, ſmooth, fleſhy, the upper half ſerrate'.

Native of Italy, Germany, Auſtria, Idria, Sileſia, in mountainous ſituations; flowering from december to march. Cultivated in 1596, by Gerarde'.—It has the name of Black Hellebore from the colour of the root; and of Chriſtmas Roſe, from the time of flowering and the colour of the corolla.

4. Stem round, a little branched at top, but not near ſo much as in the next ſort; leafy, reddiſh at the baſe, upright, ſmooth, a foot or eighteen inches in height. Leaves not of a ſtiff, leathery conſiſtence, as in the next ſpecies, but ſoft and of a lighter green; thoſe from the bottom are on long petioles, but thoſe on the ſtem ſit cloſe to their ſheaths; the leaflets (ſeven to ten) are lanceolate, acuminate, ſharply ſerrate, ſmooth, gaſhed, uſually trifid, the diviſions ſometimes deeply lobed; and at the baſe of each peduncle is a ſimilar leaf, only ſmaller. Peduncles axillary, an inch long, round; ſupporting two (ſometimes only one) nodding, green flowers. Nectaries eight or ten, the length of the ſtyles, a little ſerrate and bent in on the rims, the upper lip truncate, and ſlightly two-toothed: ſtamens fifty or more, with pale yellow anthers, not having a ſharp point; piſtils three, ſeldom four, very ſeldom five. The anthers before they are ripe are in fifteen rows, all together forming a ball. The capſules terminate in a long linear-acuminate beak, each containing about fifteen cylindric ovate ſeeds, wrinkled a little, and of a dark lead colour'.

Native of France, Italy, Auſtria, Carniola, Sileſia, Switzerland, Great Britain. As in ſeveral places near Cambridge; Yorkſhire, near Leeds; in Suſſex, near Arundel Caſtle; Kent; Oxfordſhire; Northamptonſhire; Worceſterſhire; Hampſhire; Harefield, Middleſex.—Parkinſon mentions his having ſeen it in ſome of the Northamptonſhire woods. Ray in his hiſtory gives no hint of this or the next ſpecies being natives of England; and ſeems in his Synopſis, to think that they are not aboriginals here. Bobart ſpeaks of this as growing wild abundantly in Stokenchurch woods, and many other rocky and hilly ſituations, but makes no mention of the fifth ſort being found wild in England.—In Dunglaſs-Glen, Scotland; in woods, and paſtures among buſhes. It flowers in march and april.

5. Root ſmall, but bent with a prodigious number of ſlender dark coloured fibres. The ſtem is from eighteen inches to near a yard in height, towards the bottom round, ſtrong, naked, marked with alternate ſcars, the veſtiges of former leaves; dividing and ſubdividing at top into many branches, producing great abundance of flowers] Leaves compoſed of eight or nine long narrow lobes, which join at their baſe, commonly four on each ſide united at bottom, and one in the middle on the centre of the foot-ſtalk, they are ſerrate and end in acute points; thoſe on the lower part of the ſtalk are much larger than thoſe on the upper, which are ſmall and narrow. [They are of a very deep green; but the branches, ſtipules, peduncles and flowers are of a pale yelloviſh green. At the diviſions of the branches are oval-lanceolate ſtem-claſping ſtipules deeply bifid at the extremity: at the baſe of each peduncle an ovate-lanceolate entire bracte; both theſe are frequently tinged with purple. Flowers almoſt globular, pendent, on peduncles, forming a ſort of umbel: petals roundiſh, blunt, green with purple edges: ſtamens the length of the petals, with white anthers; germs three hairy: nectaries from five to eight'.

Native of Italy, Germany, Switzerland, France, England. As between Northfleet and Gravefend in Kent; near Cambridge; Caſtle-Acre, Norfolk; Near Bungay and Brundiſh in Suffolk; Cornbury ſtone quarry in Oxfordſhire: abundantly in Suſſex; in Hampſhire, and Somerſetſhire.

Gerarde ſays, that it was wild in his time in many woods and ſhadowy places in England. He calls it Bear-foot, Setter-wort, Setter-graſs, and Oxe-heele. The three laſt names are from its uſe in rowelling kine, or making a ſeton of the root, and putting it through the dew-lap; this operation was called by the old farriers *fettering*, a corruption perhaps from ſetoning.

It flowers in november and december to march and april. Bees frequent the flowers much, early in the ſpring, though it is a plant ſo remarkably fetid.

This ſort is always green, whereas the foregoing dies down to the root every year.

Moſt, if not all the Hellebores, produce very powerful effects when uſed medicinally. The ſpecies moſt in uſe is the Helleborus niger, which is ſuppoſed to have been the plant ſo celebrated amongſt the ancients in the cure of madneſs; the taſte of the root when freſh, is bitteriſh, and according to Dr. Grew, "being chewed, and for ſome time retained upon the tongue, after a few minutes it ſeemeth to be benumbed, and affected with a kind of paralytic ſtupor, or as when it hath been burnt with eating or ſupping any thing too hot." It alſo emits a nauſeous acrid ſmell, but being long kept, both its ſenſible qualities and medicinal activity ſuffer very conſiderable diminution. Bergius has very properly attended to this circumſtance, for in deſigning its virtues he conſiders it under three different degrees of dryneſs. "Virtus *recentis* venenata, rubefaciens, veſicans; *recentis ſiccatæ* emetica, purgans; emmenagoga, antiphthiriaca, ſternutatoria; *diu conſervatæ* vix purgans, alterans, diuretica." Although many writers conſider this root as a perfectly innocent and ſafe medicine, yet we find ſeveral examples of its poiſonous effects; it ſhould therefore be uſed with proper caution. It ſeems to have been principally from its purgative quality that the ancients eſteemed this root ſuch a powerful remedy in maniacal diſorders, with a view to evacuate the *atra bilis*, from which theſe mental diſeaſes were ſuppoſed to proceed: but though evacuations be often found neceſſary in various caſes of alienation of mind, yet as they can be produced with more certainty and ſafety by other medicines, this catholicon of antiquity ſeems now almoſt entirely abandoned; it is however ſtill uſed in ſmall doſes for attenuating viſcid humours, promoting the uterine and urinary diſcharges, and opening inveterate obſtructions of the remoter glands; it often proves a powerful emmenagogue in phlethoric habits, where ſteel is conſidered as improper: it is alſo uſed in dropſies; and in ſome cutaneous diſeaſes.

A ſpecies of ſimilar though leſs powerful virtue is the Helleborus fœtidus, or common black Hellebore, a native of England; this plant is very frequently uſed in popular phyſic as an anthelmintic; the powder of the dried leaves being the preparation principally made uſe of; and this in doſes of about fifteen grains for children. The decoction of about a dram of the green leaves being conſidered as equal to fifteen grains of the dry ones; it is uſually repeated on two, and ſome-

[1] Smith. [2] Krocker, Scopoli, Curtis. [3] Hort. kew. [4] Krocker, Scopoli, Haller, Lightf. Woodw. Mſs Gærtn. [5] Woodville and Woodw. Mſs.

times three succeſſive mornings, and ſeldom fails to bring away worms, if there be any in the inteſtinal tube.

β. The lobes of the leaves in this variety are broader and the ſtalks grow taller. It grows naturally in Iſtria and Dalmatia, and is not ſo hardy as ours, inſomuch that a ſevere winter deſtroys it.]

6. This reſembles H. viridis, but differs from it in having trifoliate leaves, which are broader and entire, their ſurface alſo is ſmoother, and the ſtalks riſe higher than either of our common ſorts.

[The native place of this ſpecies is unknown. It flowers from january to may. Mr. Miller cultivated it in 1731[f].

7. Stem leafleſs. Flower minute, reſembling that of the Parnaſſia, and white, (yellow)[b].

Native of Denmark, Canada, Siberia, and Hudſon's-bay, whence it was introduced by the Hudſon's-bay Company in 1782[i]. In Canada it is ſo abundant in the woods as to cover the ground in many parts: it commonly chooſes moſſy places, that are not very wet; Wood-ſorrel and Alpine Circæa are its companions. It is called *Tiſſavoyenne jaune* by the French, all over Canada. The leaves and ſtalks are uſed by the Indians, for giving a fine yellow colour to ſeveral kinds of work, which they make of ſkins. The French dye wool, &c. yellow with this plant[k]. It flowers here in june and july.]

PROPAGATION AND CULTURE.

1. This flowers very early in the ſpring, which renders it worthy of a place in all curious gardens, eſpecially as it requires but little room; it is propagated by offſets, which the roots ſend out in plenty; theſe roots may be taken up and tranſplanted, any time after their leaves decay, which is generally by the beginning of june, till october; when they will begin to put out new fibres; but as the roots are ſmall, and nearly of the colour of the ground, ſo, if care is not taken to ſearch them, many of the roots will be left in the ground; theſe roots ſhould be planted in ſmall cluſters, otherwiſe they will not make a good appearance; for ſingle flowers, ſcattered about the borders, of theſe ſmall kinds, are ſcarce ſeen at a diſtance; but when theſe and the Snowdrops are alternately planted in bunches they will have a good effect, as they flower at the ſame time, and are much of a ſize.

[From the earlineſs of its flowering the Winter Aconite is liable to be cut off by ſevere froſts.]

3. This is propagated by parting the roots in autumn, for the ſeeds ſeldom ripen in England: in order to have it flower well, it ſhould have a more ſheltered ſituation than the common ſorts.

[Like moſt alpine plants, it loves a pure air, a ſituation moderately moiſt, and a ſoil unmanured. The flowers being injured by froſt, in order to have them in beauty, the plants ſhould be covered during winter with hand-glaſſes; or preſerved in pots in a common hot-bed frame.—Neither this nor the firſt ſort thrive very near London[l].]

4, 5. If the ſeeds of theſe be permitted to ſcatter, or ſown ſoon after they are ripe, the plants will come up early in the following ſpring, and when they have obtained ſufficient ſtrength, may be tranſplanted into woods or wilderneſs quarters, where they will thrive and flower very well in the ſhade, and make a good appearance at a ſeaſon when very few other plants are in flower.

6. [It has been uſual to treat this ſpecies as a greenhouſe plant, or at leaſt to ſhelter it under a frame in the winter: probably it is more hardy than we imagine. It is propagated by parting its roots in autumn, and by ſeeds: but few of the latter ripen in general, nor do the roots make much increaſe. To theſe cauſes we muſt doubtleſs attribute its preſent comparative ſcarcity. On account of its early flowering (in february), as well as its ſingularity, it is a deſirable plant in collections[m].

Stem leaves ſetaceous.]

DESCRIPTION, &c.

1. Root perennial, compoſed of many thick fleſhy fibres. Leaves ſpreading near the ground, and ſitting cloſe to the root at their baſe, of a light green colour, having ſix longitudinal nerves, which appear ſtrongeſt on the under ſide; they are four or five inches long, two or three broad in the middle, narrowing gradually to both ends, and continuing green all the year. In the centre of theſe ſprings up a ſingle erect ſtalk, a foot in height, having a few veſtiges of ſmall leaves, ending in ſharp points, ſtanding alternately cloſe to the ſtalk: this is terminated by a cloſe obtuſe ſpike of dark-red flowers, with petals ſpreading open flat; the filaments are twice the length of theſe; and the anthers are four-cornered, of a blue purple colour. Some of the flowers have no ſtigma, and are barren. It flowers the latter end of june (april and may, *H. K.*), and in warm ſeaſons the ſeeds will ripen here.

I was firſt favoured with this ſpecies by Mr. Peter Collinſon; and afterwards received a plant, with a drawing of it made in the country where it naturally grows, from Mr. John Bartram, junior: I have ſince been furniſhed with more plants by Dr. Benſel of German Town in Philadelphia, who found it growing plentifully in ſhady moiſt places.

[This plant is called *Star-graſs* by the natives; and is of an acrid aromatic flavour[n].

2. Stem extremely ſimple, two feet high. Leaves alternate or ſcattered, upright, even but rugged at the edge. Flowers white, in a ſimple, terminating raceme, on peduncles longer than the flowers. It reſembles an Aſphodel very much, but has three recurved ſtyles.—Native of Penſylvania[o], and Virginia. Introduced in 1765, by Mr. William Young. It flowers in may and june.[p]].

PROPAGATION AND CULTURE.

Theſe plants may be increaſed by offſets taken from the roots in autumn; or by ſeeds which ſhould be ſown as ſoon as ripe. They prefer a light freſh ſoil, and are hardy enough to thrive in the open air. They muſt not be removed oftener than once in three or four years; and they are as long in coming to flower from the ſeed.

Leaves heart-ſhaped veined.]

DESCRIPTIONS, *&c.*

1. The firſt ſort has ſtrong fibrous roots, to which hang knobs, or tubers, like thoſe of the Aſphodel, from which come out leaves, two feet long, with a rigid midrib, the two ſides drawing inward, ſo as to form a ſort of gutter on the upper ſide. The flower-ſtalks riſe two feet and a half high, having two or three longitudinal furrows; theſe are naked, and at the top divide into three or four ſhort peduncles, each ſuſtaining one pretty large yellow flower ſhaped like a Lily, having but one petal, with a ſhort tube, ſpreading open at the brim, where it is divided into ſix parts; theſe have an agreeable ſcent, from which ſome have given them the title of yellow Tuberoſe. It flowers in june, and the ſeeds ripen in auguſt.

[Parkinſon obſerves, that "this agrees with the following ſort ſo nearly, as that it might ſeem to be "the ſame; but the leaves are not fully ſo large, nor "the flower ſo great or ſpread open: the colour is "a fair yellow wholly; it is very ſweet; and it abideth "blown many days before it fade."* Hence this ſpecies does not correſpond entirely with its name of Hemerocallis or Day-Lily.

Native of Siberia, Hungary, Dalmatia, Iſtria; it has eſtabliſhed itſelf in Switzerland, Sileſia, &c.

"Theſe Lilies," (this and the following ſpecies) ſays Gerarde, "do grow in my garden, and in the "gardens of herbariſts and lovers of fine and rare "plants." He calls it Liriconfancie or Yellow Lillie. By Parkinſon it is named Yellow Day-Lilly.]

β. The variety has ſmaller roots; the leaves are not near ſo long, have not more than *half* the breadth, and are of a dark green colour. The flower-ſtalk is a foot and *half* high, naked and compreſſed, without furrows; at the top are two or three yellow flowers, which are nearer the bell ſhape than the others, and ſtand on ſhorter peduncles. This flowers the beginning of june, and the ſeeds ripen early in auguſt. It grows naturally in Siberia.

2. This is a much larger plant than the firſt, and the roots ſpread and increaſe much more, therefore it is not proper furniture for ſmall gardens; the roots have very ſtrong fleſhy fibres, to which hang large oblong tubers. The leaves are near three feet long, hollowed like thoſe of the former, turning back toward the top. The flower-ſtalks are as thick as a man's finger, and riſe near four feet high; they are naked, without joints, and branching at the top, where are ſeveral large copper-coloured flowers, ſhaped like thoſe of the Red Lily, and as large. The ſtamens of this ſort are longer than thoſe of the other, and their ſummits are charged with a copper-coloured farina, which ſheds on being touched. Theſe flowers never continue longer than one day, but there is a ſucceſſion of flowers on the ſame plants for a fortnight or three weeks; it flowers in july and auguſt.

[This, ſays Linnæus, ſeems to be ſpecifically different from the foregoing, though no real difference is diſcovered: it is larger in ſize, the corolla is copper-coloured, and the flowers appear later. To theſe diſtinctions we may add, that the flowers of the *fulva* have little or no ſmell, whereas thoſe of the *lutea* are very fragrant; that the former are much ſhorter lived; and that they are ſeldom or never ſucceeded by ſeed; whereas the *lutea* generally produces ripe ſeed. Certainly none of theſe circumſtances can be admitted as genuine ſpecific differences, and yet it is remarked by Mr. Curtis, that when the ſeveral characters in which the *fulva* differs ſo eſſentially from the *flava*

* Parad. 148.

are

are attentively conſidered, we ſhall wonder that Linneus could entertain an idea of their being varieties of each other. He obſerves, that the leaves of this ſpecies on their firſt emerging from the ground, and for a conſiderable time afterwards are of the moſt delicate green imaginable; that the appearance which the plant aſſumes at this period of its growth is indeed ſo pleaſing, as to conſtitute half its beauty; that its bloſſoms are twice the ſize of thoſe of the *flava*, of a tawny orange colour without gloſs or ſmell, the petals waved on the edge, and the flowers rarely or never ſucceeded by ripe capſules.

In contradiction to this opinion, I cannot but relate a caſual experiment communicated to me by my ingenious friend Miſs Welch of Ardenham-hill, near Ayleſbury. In the year 1788 ſhe removed ſeveral plants from Hampſtead to a new garden ſhe was then making in Buckingamſhire. The ſoil was a ſtiff clay manured with pond mud, ſand, and dung in ſome parts; in others it was a compoſt formed of the ruins of buildings and limeſtone, mixed with a mould produced from a variety of animal and vegetable ſubſtances. The plants were firſt placed in the clayey ſoil. Among them was a ſingle plant of Hemerocallis fulva. The ſucceeding year ſhe divided this plant, and put part of it in a ſhallow bed of the compoſt formed from the ruins, &c. It ſhot very freely, ſo that ſhe was able to take off another part of the plant, and the ſame ſummer ſet it in the ſame bed. When the laſt plant flowered ſhe was agreeably ſurpriſed with the ſight of an Hemerocallis flava, which ſhe is poſitive ſhe was not poſſeſſed of, till it was thus produced by accident. The year after, ſhe had plants varying in ſize and colour, large and of a deep tawny hue, ſmall and abſolutely yellow, and alſo of a pale tawny, and of a ſize between *fulva* and *flava*[b]. The change of colours in flowers occaſioned by removing plants into a ſoil of a different nature, is a circumſtance well known to floriſts[c].

Its natural place of growth was not known to the old botaniſts. Linneus makes it to be a native of China. Father Loureiro ſays it is cultivated there and in Cochinchina, but does not affirm that it is a native. Thunberg inſerts it among the Japoneſe plants in theſe words—*creſcit hinc inde, ſæpe culta*: it grows here and there, often cultivated. In the catalogue of the Royal Garden at Kew, it is ſaid to be a native of the Levant. Does not this uncertainty favour the idea of its being rather a variety than a diſtinct ſpecies?

In Japan it varies with a double flower, and with variegated leaves[d].

In China and Cochinchina the inhabitants boil the flowers, both freſh and dry, commonly with their meat[e].

3. Leaves next the ground acuminate, ſpreading at the tip, entire, upright, deep green on the upper ſurface, a finger's length; ſome almoſt a hand, others only an inch broad: petioles channelled, fleſhy, awl-ſhaped, ſmooth, longer than the leaf. Scape round, jointed, upright, ſmooth, longer than the leaves. Bractes at the joints of the ſcape and under the peduncles ovate, concave, ſmooth. Flowers at the top of the ſcape in racemes, drooping. Peduncle round, ſmooth, half an inch in length. Corolla white; tube furrowed, half an inch long. Filaments longer than the corolla, equal, filiform, faſtened to the baſe of the corolla by the ſide of the germ; which is ovate and ſmooth; ſtyle longer than the ſtamens; ſtigma ſimple, white. Capſule oblong, ſix-furrowed, ſmooth.

Native of Japan, and frequently kept in gardens and houſes there, for its elegance: flowering in auguſt and ſeptember[f].

4. Leaves radical, petioled, acuminate, very finely veined tranſverſely, ſmooth, a hand in length. Petioles winged, membranaceous, a hand in length or rather more. Flowers as in the foregoing ſpecies.—Native of Japan[g].

5. Stem round, upright, ſmooth, a foot high or more. Leaves alternate, petioled, ovate-oblong, acute pale underneath, ſmooth on both ſides, upright, a ſpan long, and a hand broad, the younger ones gradually ſmaller and leſs cordate: petioles compreſſed, winged, the length of the leaf. Flowers terminating, alternate, upright. Capſule an inch in length, ovate, angular, ſmooth, ſix-valved, ſix-celled. Seeds numerous in each, imbricate, orbiculate, depreſſed, ſmooth, ſurrounded with a membranaceous wing[h];—obovate-triangular, leafy-compreſſed, diaphanous; edged with a very thin, broad, tranſparent membrane, of a ſhining golden colour, with two opake lines from the baſe towards the nucleus[i].

Gærtner doubts whether this be a genuine ſpecies of Hemerocallis, ſince it differs ſo much in the fruit.

Native of Japan, and frequently cultivated there[k].]

PROPAGATION AND CULTURE.

1, 2. Theſe plants are eaſily propagated by offſets, which the roots ſend out in plenty; they may be taken off in autumn, that being the beſt ſeaſon for tranſplanting the roots, and planted in any ſituation, for they are extremely hardy, and will require no other culture but to keep them clean from weeds, and to allow them room that their roots may ſpread; the firſt ſort may alſo be propagated by ſeeds, which if ſown in autumn, the plants will come up the following ſpring, and theſe will flower in two years; but if the ſeeds are not ſown till ſpring, the plants will not come up till the year after.

In a moiſt ſoil and ſhady ſituation they thrive better than in dry ground. [From their ſize, and the great increaſe of their roots, eſpecially in the ſecond ſort, they are moſt proper for large gardens and plantations.

HEMEROCALLIS. See *Aſphodelus*, *Lilium*, *Pancratium*.

——— LILIASTRUM. See *Anthericum*.

HEMIMERIS.

Lin. gen. Schreb. n. 1016. *ſuppl.* 45. *Thunb. nov. gen.* 74. *Juſſ.* 120.

Claſſ. 14. 2. Didynamia Angioſperma.

Nat. order of *Perſonatæ.—Scrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted almoſt to the baſe, much ſhorter than the corolla: *parts* ovate, unequal, permanent.

COR. monopetalous, wheel-ſhaped, ringent: *tube* very ſhort (ſcarcely any), intruded, white. *Upper lip*, cloven, with a kind of bag at the baſe compoſed of little nectareous pits: *lower* concave, blunt.

STAM. *Filaments* two or four, filiform, inſerted into the baſe of the lower lip, bent round. *Anthers* very ſmall, heart-form, cohering, yellow.

PIST. *Germ* ſuperior, ſharp, ſmooth. *Style* thread-form, of the ſame length and in the ſame ſituation with the ſtamens. *Stigma* ſimple, ſharpiſh.

PER. *Capſule* ovate, ſharp, twin, gibbous at the baſe on one ſide, two-celled, two-valved.

SEEDS very many, ſmooth.

OBS. *Allied to* Antirrhinum, *but differing in the form of the corolla.*

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* wheel-form: upper lip cloven, with a nectareous bag at the baſe.

SPECIES

1. Hemimeris ſabuloſa.
Lin. ſyſt. 561. *ſuppl.* 280.
Diandrous; leaves oppoſite pinnatifid, ſtem proſtrate.
2. Hemimeris montana.
Lin. ſyſt. 561. *ſuppl.* 280.
Diandrous; leaves oppoſite, ovate, ſerrate; ſtem upright.
3. Hemimeris diffuſa.
Lin. ſyſt. 561. *ſuppl.* 280.
Didynamous; leaves alternate and oppoſite pinnatifid; ſtem patulous.
Native of the Cape. Detected there by Thunberg. Perhaps the ſecond may be only a variety of the firſt ſpecies.

HEMIONITIDI AFFINIS. See *Polypodium*.

Fronds palmate birſute.
5. Hemionitis japonica.
Lin. ſyſt. 932. *Thunb. jap.* 333.
Fronds bipinnate: pinnas lanceolate entire.
6. Hemionitis reticulata.
Forſt. fl. auſtr. n. 423.
Fronds lanceolate-ſickled quite entire, veins netted.
7. Hemionitis eſculenta.
Retz. obſ. 6. 38. *n.* 83.
Frond pinnate, pinnas alternate lanceolate crenate ſlightly cared at the baſe.
8. Hemionitis prolifera.
Retz. obſ. 6. *n.* 84.
Frond pinnate, decumbent, pinnas lanceolate crenate, axils proliferous.

DESCRIPTIONS, &c.

The five firſt of theſe Ferns are natives of the Weſt Indies, the ſixth has been lately diſcovered in the Society iſles, and the two laſt were obſerved by Koenig in the Eaſt-Indies.

1. The leaves are plain and ſimple, ſeldom exceeding ſixteen or eighteen inches in length, when moſt luxuriant; they grow in tufts from a ſtrong fibrous root. This plant is commonly found on the trunks of trees in the cooler and more ſhady inland woods of Jamaica[a].

2. Native of Jamaica[b].

3. Leaves about two inches long, and one and a half over where broadeſt.—Creeping on trees in the cooler inland woods of Jamaica[c].

4. Roots many, fibrous, black. Stalks black, cornered, about ſix inches high, covered with ferruginous hair. Frond divided into three parts, cut in almoſt to the centre; the two under ſections having ears or appendicles making the leaf appear divided into five ſections: the middle diviſion largeſt, an inch and half long, and half as broad in the middle, eaſily dented on each ſide, rough, of a yellowiſh green colour; each ends in a point, and has a purple midrib, from which go ſeveral tranſverſe fibres, on which is the ſeed. The whole frond is like the leaf of the creeping Ranunculus. Between Savanna and Two-mile wood in Jamaica[d].—Found alſo in Martinico, by Plumier.

5. The whole frond is ſmooth with a furrowed ſtipe, at bottom bipinnate, at top pinnate. Pinnas and pinnules *lanceolate, acute, entire*, pale underneath. The *fructifications* are in trichotomous lines over the whole lower ſurface. Native of Japon[e].

6. Native of the Society iſles[f].

7. A foot and half high or more. Stipe ſmooth, grooved. Pinnas almoſt ſeſſile, deeply notched, each notch at the baſe next the ſtipe more deeply cut and elongated: the terminating pinna as it were ſagittate. Roots eſculent.

8. Primary frond pinnate, decumbent, large pinnas ſeſſile, alternate, truncate at the baſe, almoſt half a foot in length: from the axils of theſe other fronds grow frequently in pairs, a foot and half long, with ſimilar pinnas, only much ſmaller, and the ſtipe thickened like a tubercle[g].]

PROPAGATION AND CULTURE.

Theſe are plants ſeldom propagated in gardens. They muſt be procured from the countries where they naturally grow; planted in pots filled with loamy undunged earth, and placed in the ſtove: in ſummer they muſt be frequently watered, but in winter they require little. In ſummer they ſhould have plenty of free air.

DESCRIPTIONS, *&c.*

1. [Root biennial, thick, yelloviſh without, white within, running deep into the ground, ſweet to the taſte, with ſome acrimony. Stem two, three, and four feet high, round, furrowed, rough, with white hairs, hollow within, branched from the bottom. Leaves hairy and ſcabrous, frequently a foot in length, and more than half a foot in breadth, pinnate and waved, the pinnas pinnatifid, lobed, ſerrate, the odd one cloven into three to the baſe. The petioles ſpread out at the baſe into a membranaceous bag, woolly at the edge, and ſheathing the umbels in their younger ſtate. The univerſal involucre conſiſts only of one or two leaflets, and is ſometimes wanting. The partial involucre has from ſix to eight linear leaflets. The univerſal umbel is flat, and has ten, twelve or more rays; the partial umbel has upwards of thirty. Florets white, greeniſh white, or purpliſh; they have a horned appearance before they expand, particularly the outer ones: theſe are very irregular, having their outer petals four times the ſize of the inner ones. In the central florets, they approach much nearer to regularity. Anthers greeniſh. Stigmas ſemitranſparent. Seeds large, ſmooth, ſcarce viſibly ſtriated in the middle, having three riſing ridges on each ſide; the leafy border is often purpliſh.—The central flowers are frequently abortive *.

Native of moſt parts of Europe, in hedges and paſtures, orchards, and near water; particularly in moiſt and fertile ſoils. It flowers from may to july.

The ſeeds have a ſtrong ſmell, ſomewhat like that of a bug; they are accounted diuretic and ſtomachic. Linneus ſays that the plant is uſed in Scania againſt the dyſentery.

Gmelin informs us that the inhabitants of Kamtſchatka, about the beginning of july, collect the footſtalks of the radical leaves, and after peeling off the rind, (which is very acrid) dry them ſeparately in the ſun, and then tying them in bundles, lay them up carefully in the ſhade in bags: in this ſtate they are covered with a yellow ſaccharine efflorescence, taſting like liquorice; this, being ſhaken off, is eaten as a great delicacy.

The Ruſſians diſtill an ardent ſpirit from the ſtalks thus prepared, by firſt fermenting them in water with the greater Billberries (Vaccinium uliginoſum); which Gmelin ſays is more agreeable to the taſte than ſpirits made from corn.

The leaves are a favourite food with Rabbets and Swine. Kine, Goats and Sheep alſo eat them; but horſes are ſaid not to be fond of them *.

In German it is named *Heilkraut, Barenklau*, &c. In Dutch *Heilkruid, Beerenklauwe*. In Daniſh *Bjorneklov*. In Swediſh *Bjorufloka*. In French *La Berce*. In Italian *Sfondilio*. In Spaniſh *Eſpondilio*. In Portuguese *Canobraz*. In Ruſſian *Putſchki; Slatkoja trawa*.

Our old writers call this plant *Cow-parſnep, meadow Parſnep*, and *Madnep*. In Norfolk it is called *Hogweed*. The dry ſtalks are named, in common with thoſe of ſome other umbellate plants, *Kexes* or *Kexſticks*.

2. The pinnas of the leaves are moſtly three lobed; the lower lobes long, and ſtanding nearly at right angles, which gives the cruciate appearance; lobes linear-lanceolate, deeply ſerrate, and the ſerratures again ſerrate. It is however merely a variety of the foregoing, and grows plentifully at Berkhamſtead in Hertfordſhire, near the place where Ray found it; and where both ſorts may be ſeen growing from the ſame root. The diſtinction of the floſculoſe and radiate corolla is very uncertain, as Hudſon well remarks *.

Ray, who cultivated it in his garden at Cambridge, looks upon it as a mere variety: and Hudſon expreſsly affirms that it degenerates to the foregoing, in a garden.

Linneus thus diſtinguiſhes it.—The ſtature is the ſame with that of H. Sphondylium, but the leaflets are extremely narrow, linear, at the common petiole pinnate croſswiſe, being four at each joint; the anterior leaflet lobed at the baſe. Flowers uniform, green and white. According to Krocker, dark or yelloviſh green, not white.

β. This differs from the common ſort in having the ſegments of the leaves very long, the primary ones being from half a foot to a foot in length, oblong, lanceolate, acute, ſmooth above, rough underneath, rarely and ſhortly ſubdivided: whilſt the plant is young the leaves are palmate, divided into long ſegments: ſtem hirſute, with white hairs, four feet high, ſtriated, furrowed: univerſal involucre either none, or like the partial one, with many linear, acute leaflets: petals white, ſubovate, bent in, the outer ones larger, cloven half way.

* Ray, Wichering, Pollich, Krocker, Necker, Leers.

* Gmelin, Witherig, Lightfoot. * Woodw. Mſ.

γ. In

γ. In the seed, flowers, anthers and pistils this agrees with H. longifolium; in the leaves it approaches nearer to H. angustifolium: it differs from both in having the segments of the leaves very narrow, shorter, very confluent: the leaves are mostly ternate, being divided into four or five segments only in the larger ones[a].

These three are rather to be considered as singular varieties than as species: hence Crantz has united them under the name of *H. proteiforme*.

3. Root biennial. Stem deeply furrowed, hispid. Leaves convex, even. Flowers flosculose, by no means radiate. Petals green, bent in, not at all emarginate. Universal involucre none. Pedicels or partial peduncles scabrous. At the base of the leaf-sheathes a thick white beard.—Native of Siberia[b].

From this species a spirit is drawn at Kamtschatka, called *Raka*, as related in *Cook's voy.* 3. 337. *where the process of making the spirit is described.* It is used also as food, like the first sort.—Mr. Miller cultivated it in 1768[c].

4. Root biennial. Stem much taller than the common sort, attaining the height of six feet, hirsute, round, slightly angular, branched. Leaves on long, channelled, rough petioles, tinged with purple, arising from a very large, obtuse, hirsute sheath; they have one pair of petioled pinnas, and a second pair sessile, with an odd one compofed of three blunt lobes; they are rough on both sides, without hairs on the upper, and only on the ribs in the under surface, which is downy: they are the largest in this genus, sharply serrate, gashed and sinuate. Flowers large, radiate, greenish or yellowish white.—This species is of the same nature with the others, and is used for the same purposes[d].

Native of Italy, Silesia and Siberia. Cultivated by Gerarde in 1597. He calls it Hercules All-heal.

5. Root knotty, with circles round it, and a few fibres. Stem from a foot to two feet in height, slightly angular, striated, solitary, smooth, soft, with a white pile only towards the top, scarcely branched. Leaves dusky green, on long hirsute petioles, pinnas sessile, gashed, three or five, lanceolate, rounded and eared, the outer odd one petioled, three-lobed, the lobes like the other pinnæ, in the lower ones blunt, in the upper one sharp, all serrate. Universal involucre one-leafed or none: partial sometimes of more, sometimes of fewer lanceolate, hirsute leaflets, at first spreading, afterwards bent back. Umbel eight or ten-cleft: in the umbellule, the rays are more in number, and more hirsute. Petals deeply and unequally cut, before they open reddish, and then from rose-colour becoming white. It differs from H. Panaces, in having the leaves veined and wrinkled, green, and scabrous on both sides; not soft, or paler underneath, or somewhat tomentose; peduncles scabrous, not even, as in H. Panaces: the stature is less[e].—Native of Austria, Carniola and Silesia; flowering in july and august.—Cultivated in 1748, by Mr. Miller[f].

6. Stem from eighteen inches to three feet high, round, smooth, jointed. Leaves smooth, thick, those next the root on long roundish petioles; subcordate, gash-serrate, not lobed; the stem-leaves gradually smaller, the upper ones very small, more three-lobed, and sinuate, sessile. Sheaths striated, whitish, smooth, often wanting in the lower leaves. Corollas white, radiate, smaller than in the rest[g].—Seguier joins this with the foregoing species, but the leaves resemble those of Rubus Chatmæmorus, or the Fig, and are even, not scabrous, on their upper surface[h].—Native of the Swiss Alps, Provence and Silesia.—Known to Caspar Bauhin in 1595[i].—Cultivated in 1739, by Mr. Miller[k].]

PROPAGATION AND CULTURE.

Sow their seeds in the autumn; in the spring, when the plants are up, hoe the ground, cutting up the weeds, and thinning the plants, as directed for Parsneps.

DESCRIPTION, *&c.*

This is a tree with alternate, oval-oblong, obtuse, perennial, thick, veined, smooth, quite entire, petioled leaves[a].

Native of the East-India islands. Found on Ceylon by Koenig, and on Pulo Condore, by Mr. Dav. Nelson.—Introduced in 1780, by Sir Joseph Banks, Bart.—Arunus littorea of Rumphius (amb. 3. 95. t. 63.) agrees with this entirely in the leaves and fruit, but the flowers described by him are very different[b].

HERMANNIA. *(This name was given by Tournefort, in memory of the celebrated Paul Hermann, who practised physic in Ceylon and at the Cape of Good Hope, and was afterwards professor of Botany at Leyden.)*

Leaves wedge-ſhaped, marked with lines, plaited, crenate-emarginate.

[8. Hermannia odorata. *Sweet-ſcented Hermannia.*
Ait. hort. kew. 3. 412.
Leaves oblong-lanceolate, tomentoſe, wrinkled underneath, the lower ones truncate and toothletted; calyxes pitcher-ſhaped and angular.]

9. Hermannia hyſſopifolia. *Hyſſop-leaved Hermannia.*
Lin. ſpec. 942. *ſyſt.* 610. *Reich.* 3. 303. *hort. cliff.* 342. *upſ.* 195. *Giſeck ic.* 1. *t.* 16.
Leaves lanceolate, blunt, ſerrate.

10. Hermannia lavendulifolia. *Lavender-leaved Hermannia.*
Lin. ſpec. 942. *Reich.* 3. 303. *hort. cliff.* 342. *Dill. elth.* 179. *t.* 147. *f.* 176. *Curt. magaz.* 304.
Leaves lanceolate, blunt, quite entire.

[11. Hermannia denudata. *Smooth Hermannia.*
Lin. ſyſt. 611. *ſuppl.* 301. *Cavan. diſſ.* 6. 329. *t.* 181. *f.* 1.
Leaves lanceolate, ſharp, even, ſerrate at top.

12. Hermannia glabrata.
Lin. ſyſt. 611. *ſuppl.* 301.
Leaves lanceolate, ſharp, gaſh-ſerrate, ſmooth, flowers drooping.

13. Hermannia ciliaris.
Lin. ſyſt. 611. *ſuppl.* 302.
Leaves lanceolate, ſharp, entire and ſerrate, ciliate.

14. Hermannia linifolia.
Lin. ſyſt. 611. *Reich.* 3. 303. *Burm. prodr.* 18.
Leaves linear, peduncles one-flowered.

15. Hermannia fillifolia.
Lin. ſyſt. 611. *ſuppl.* 302.
Leaves linear, three-ſided, quite entire.

16. Hermannia triſoliata.
Lin. ſpec. 942. *Reich.* 3. 303. *hort. cliff.* 342. *mant.* 431.
Leaves ternate, ſeſſile, plaited, reticulate, tomentoſe.

17. Hermannia triphylla.
Lin. ſpec. 942. *Reich.* 3. 304. *amæn. 6. afr.* 25.
Leaves ternate, petioled, ſmooth, obovate.]

18. Hermannia groſſularifolia. *Gooſeberry-leaved Hermannia.*
Lin. ſpec. 943. *ſyſt.* 611. *Reich.* 3. 304.
Leaves lanceolate, pinnatifid.

[19. Hermannia pulchella.
Lin. ſyſt. 611. *ſuppl.* 302.
Leaves lanceolate, pinnatifid, pinnas entire and gaſhed; ſtem upright, even.

20. Hermannia diffuſa.
Lin. ſyſt. 611. *ſuppl.* 302.
Leaves lanceolate, pinnatifid, pinnas entire and toothed; peduncles capillary, two-flowered; ſtem procumbent.]

21. Hermannia hirſuta.
Mill. dict. n. 8.
Leaves ſimple and ternate, hirſute, ſeſſile.

DESCRIPTIONS, &c.

[The Hermannias are Shrubs from eighteen inches to ſix or ſeven feet in height. Natives of the Cape of Good Hope. Leaves alternate, ſimple, ſtipuled. Flowers axillary and terminating, frequently two together. Corolla yellow.]

1. This ſeldom riſes more than two feet and a half high, the ſtem is not very woody, and the branches are ſoft and ſlender. The flowers are produced in looſe panicles at the ends of the branches; they are larger than thoſe of the Alder leaved ſort, and have hairy calyxes: they come out in june and july, and frequently again in the autumn.

[Peduncles from the axils of the leaves, commonly three together, producing at the top two flowers on each, under three lanceolate leaflets [a].

Cultivated in 1728, by Mr. Miller [b].

2. Found at the Cape by Mr. Maſſon, and introduced in 1774. It flowers in november and december.

3. This alſo was found at the ſame place by Mr. Maſſon, and was introduced at the ſame time. It flowers from april to june [c]. The whole plant is covered with a very white down. The leaves are ſerrate, except near the baſe.

4, 5. Found at the Cape by Thunberg [d].

6. This is very nearly allied to H. alniſolia. Leaves hoary, ſcarcely tomentoſe, hardiſh, the lower ones blunt and three-cuſped. Flowers in a terminating raceme, alternate, hanging down, moſtly ſolitary. Petals blue, leſs cowled than the others [e].]

7. This riſes with a ſhrubby ſtalk ſix or eight feet high, dividing into many erect irregular branches covered with a brown bark. Leaves narrow at their baſe, but broad and round at the top, about an inch long, and three quarters of an inch broad at the top. The flowers are produced in ſhort ſpikes on the upper part of the branches; they are of a pale yellow colour, and ſmall: they appear in april and may, and the ſeeds often ripen in auguſt.

[The capſule is within the calyx, which is ſlightly inflated; it is on a very ſhort peduncle; the texture is thin, and the colour is bay: the partitions are faſtened to the middle of the back of the valves, and the ſeeds are fixed to the central margins of the partition on both ſides: theſe are eight to twelve in each cell, ſmall, of an angular kidney form, ſmooth, dirty cinnamon colour; with a tubercled navel in the middle of the belly [f].

Cultivated in 1728, by Mr. Miller [g].

8. Found at the Cape by Mr. William Paterſon; and introduced in 1780 by the Counteſs of Strathmore. It flowers moſt part of the year [h].]

[a] Linn. ſpec. [b] Hort. kew. [c] Ibid.
[d] Linn. ſuppl. [e] Linn. amœn. [f] Gærtner
[g] Hort. kew. [h] Ibid.

9. This riſes with a ſhrubby upright ſtalk to the height of ſeven or eight feet, ſending out many woody lateral branches, growing very erect. Leaves about an inch and half long, and half an inch broad, ſerrate towards the end: the flowers come out in ſmall bunches from the ſide of the ſtalk; they are of a pale ſtraw-colour, appear in may and june, and are frequently followed by ſeeds, which ripen the latter part of auguſt.

[Leaves broader than in the next ſpecies. Calyxes inflated. Umbel of the corolla very ſhort, ſulphur-coloured, reflex. Stem upright, ſtiff[t]. Cultivated in 1725, by Mr. Miller[u].]

10. This ſort has ſhrubby branching ſtalks, which are very buſhy, but ſeldom riſe more than a foot and half high; the branches are very ſlender, and have hairy, pale-green leaves on them of different ſizes; ſome of them are two inches long, and an inch broad at their ends, but their common ſize is ſeldom more than one inch long, and half an inch broad; they are entire, and ſit pretty cloſe to the branches. The flowers come out from the ſide of the ſtalk ſingly, are ſmall and yellow; they continue moſt part of the ſummer.

[Cultivated in 1732, in Dr. Sherard's garden at Eltham[v].

11 Stems upright, round, ſmoothiſh, ſtiff. Leaves petioled, remote, three-nerved underneath: floral leaves quite entire. Stipules lanceolate, ſcarcely longer than the petioles, nerved. Flowers from the top, from the alternate oppoſitions of the ſtipules, or from a two-flowered peduncle, peduncled. Calyx even, half-five-cleft. Corolla yellow. Found at the Cape by Sparrmann[w]: and by Mr. Fr. Maſſon. Introduced 1774. It flowers from may to july[x].

12, 13. Found at the Cape, by Thunberg. The latter will be a ſpecies of Mahernia, if that genus is to be ſeparated from Hermannia[y].

14. Native of the Cape, with all the other ſorts.

15. Found at the Cape by Thunberg[z].

16. Stem creeping: branches narrow. Leaves ternate; the middle leaf wedge-ſhaped, doubled, ſubſerrate, three-toothed, with the tip recurved. Flowers pendulous. Calyx bell-ſhaped, tomentoſe, half-five-cleft; the clefts dilated, rounded. The corolla narrower than the calyx[a].

17. Stems herbaceous. Stipules ſmall. Petals the length of the leaves. Peduncles ſtill longer, five-flowered, with braćtes. The whole plant has hairs thinly ſcattered over it[b].]

18. This is a ſhrub of lower ſtature than the Alder-leaved ſort, but ſends out a greater number of branches, which ſpread wide on every ſide; the leaves are ſmaller than in that, are rough and ſeſſile. The flowers are produced in ſhort cloſe ſpikes at the end of every ſhoot, ſo that the whole ſhrub ſeems covered with them; they are of a bright yellow, and appear towards the end of april, but are not ſucceeded by ſeeds in England.

[19, 20. Found at the Cape by Thunberg[c].]

21. This riſes with a ſhrubby hairy ſtalk about two feet high, ſending out many ſide branches, which grow very erect. Leaves oblong, veined, ſingle or in threes, in the latter caſe the middle leaf is largeſt. The flowers are produced towards the end of the branches; they are large, and of a deep yellow colour, with large, ſwollen, hairy calyxes. It continues flowering moſt part of the ſummer. Mr. Miller raiſed this from ſeeds which came from the Cape of Good Hope.

PROPAGATION AND CULTURE.

Theſe plants are all propagated by planting cuttings of them during any of the ſummer months, in a bed of freſh earth, obſerving to water and ſhade them until they are well rooted, which will be in about ſix weeks after planting; then take them up, preſerving a ball of earth to their roots, and plant them into pots filled with light freſh earth, placing them in a ſhady ſituation until they have taken freſh root; after which they may be expoſed to the open air, with Myrtles, Geraniums, &c. until the middle or end of october, when they muſt be removed into the the green-houſe, obſerving to place them in the cooleſt part of the houſe, where they may have as much free air as poſſible; for if they are too much drawn in the houſe, they will appear very faint and ſickly, and ſeldom produce many flowers; whereas, when they are only preſerved from the froſt, and have a great ſhare of free air, they will appear ſtrong and healthy, and produce large quantities of flowers in april and may, during which ſeaſon they make a very handſome appearance in the green-houſe: they muſt alſo be frequently watered, and will require to be new potted at leaſt twice every year, i. e. in may and ſeptember; otherwiſe their roots will be ſo matted, as to prevent their growth.

Theſe plants rarely produce good ſeeds with us, except the ninth and twenty-firſt ſorts, which ripen their ſeeds every year in England; the others rarely producing any, I ſuppoſe this may be accounted for by their having been long propagated from cuttings; for thoſe plants which I have raiſed from ſeeds, have been fruitful two or three years after, but I have always found thoſe plants which have been propagated by cuttings taken from theſe, have ſoon become barren: the ſame thing I have obſerved in many other plants, therefore thoſe who are deſirous to continue their plants fruitful, ſhould conſtantly raiſe them from ſeeds. Theſe as alſo thoſe which are obtained from abroad, muſt be ſown upon a moderate hot-bed; and when the plants come up, they muſt be tranſplanted into ſmall pots, and plunged into another very moderate hot-bed, in order to promote their rooting; after which they muſt be hardened by degrees, to endure the open air in ſummer, and may then be treated as the old plants.

[Hermannia pinnata. See *Mahernia*.

HERMAS. *(Ερμης, is one of the names of Mercury. But I preſume that this plant may derive its name from* Ερμα, *a prop.)*

Lin. gen. Reich. n. 1270. *Schreb.* 1594. *Juſſ.* 225. *Gærtn. t.* 85.

Claſſ. 23. 1. Polygamia Monoecia.

Nat. order of *Umbellatæ* or *Umbelliferæ*.

GENERIC CHARACTER.

* *Hermaphrodite, umbel terminating.*

CAL. *Umbel univerſal* many-rayed, hemiſpheric.—*Partial* many-rayed: central ray flower-bearing; the reſt without any floret.

Involucre univerſal many-leaved, lanceolate, ſhort, permanent.—*Partial* of one or two leaves, lanceolate, the length of the partial umbel.

Proper perianth obſcure, five-toothed.

COR. *univerſal* floſculous.—Of the *proper*, petals five, oblong-ovate, upright, flat, entire, equal.

STAM. *Filaments* five, filiform, ſhorter than the petals. *Anthers* barren, oblong.

PIST. *Germ* inferior, compreſſed, larger than the corolla. *Styles* two, filiform, upright, longer than the corolla. *Stigmas* obtuſe.

PER. none. *Fruit* orbicular, emarginate at the baſe, gaping at the angles.

SEEDS two, cordate orbicular, compreſſed, flat, margined, marked with a ſingle longitudinal elevated ſtreak.

* *Male, umbels lateral, later, of the ſame plant.*

CAL. *Umbel univerſal* as of the hermaphrodite.

Partial many-rayed; the rays all flower-bearing.

Involucre as in the hermaphrodites.

Perianth ſcarcely any.

COR. as in the hermaphrodites.

STAM. *Filaments* five, filiform, length of the corollet. *Anthers* pollen-bearing, oval, nearly twin.

ESSENTIAL CHARACTER.

HERM. *Umbel* terminating. *Involucre* univerſal and partial. *Umbellets* with truncate rays, the central one floriferous. *Pet.* five. *Stam.* five, barren. *Seeds* in pairs, ſubor-biculate.

MALE. *Umbels* lateral, with univerſal and partial involucres. *Umbellets* many-flowered. *Pet.* five. *Stam.* five, fertile.

Stem ſmooth, leaves ovate, five-toothed, tomentoſe underneath, umbel ſolitary.

5. Hermas ciliata.
Lin. ſyſt. 913. *Suppl.* 436.
Stem ſmooth, leaves ovate, ciliate, tomentoſe underneath, umbels ſeveral.

DESCRIPTIONS, *&c.*

1. This is an umbelled plant, with the leaves radical, ſubpetioled, cordate, coriaceous, white tomentoſe underneath. Stem high, ſimple, naked, with two or three alternate, remote, little ſcales. Peduncles from the boſom of the ſcales and the top of the ſtem. Umbels at the ends of the ſtem and branches, pedunced, compound: the end one hermaphrodite female, many-rayed, with ſeveral univerſal and partial pedicels; florets of the umbellets only ſolitary, the reſt of the pedicels being truncate without a flower: the lateral umbels male, with all the rays of the umbels flower-bearing. Native of the Cape of Good Hope [a].

2. Leaves radical, petioled, obſcurely crenate, a foot in length, and a ſpan in breadth, the upper ſurface villoſe, the lower very cloſely white-tomentoſe. Stem four feet high, with a ſmall leaf or two towards the lower part; the axils villoſe. Umbel terminating, pedunced; and below this four flowering branchlets in whorls, with one or two lower branches, which are alſo floriferous. Involucre many-leaved, linear, acute, ſhorter than the umbel. Primordial rays very abundant. Involucels commonly three-leaved, lateral, the length of the flowers. Rays of the umbellets ſeveral. Petals lanceolate. Stamens five. The wool ſcraped from the leaves is uſed for tinder at the Cape of Good Hope, as that from Artemiſia is in China and Japan.

3. Leaves petioled, radical, bluntiſh, an inch long, veined, white-tomentoſe underneath. Scape leafleſs, pubeſcent, half a foot high. Heads three, alternate, pedunced, compoſed of florets ſcarce viſibly pedicelled, as in the flowers of the claſs Syngeneſia. Univerſal involucre conſiſting of about eight lanceolate leaflets, the length of the flowers. Rays of the umbel very ſhort. Involucels of the umbellets of a ſingle, lanceolate, lateral leaflet. Florets pedicelled; males two or three, white. Petals entire. Stamens five.

4. This is very diſtinguiſhable from the reſt by its ſmall leaves, with five nice, deep ſerratures.

5. This, with all the reſt, is a native of the Cape of Good Hope; where the two laſt were diſcovered by Thunberg [b].

Leaves ovate, petioled at the baſe.

DESCRIPTIONS, *&c.*

Theſe are trees, the wood of which is whitiſh and brittle. The leaves are alternate, peltate or ſubpeltate. The flowers are borne in ſpikes or corymbs, axillary or terminating, on peduncles each having one bracte, within a four-leaved involucre, and bearing three flowers, two male on pedicels, and one female ſeſſile. This genus is related to *Myriſtica*, notwithſtanding the inner ſuperior calyx [c].

1. This is an upright, lofty tree, with an elegant head. The flowers are of a pale yellow colour, in panicled racemes; the calyxes of the fruit are yellow [b].]

It is very common in the Weſt-Indies, in gullies near rills of water; the Engliſh there call it Jack-in-a-box, [and the French Myrobolan. If it be Rumphus's plant, it is alſo a native of the Eaſt-Indies.

It has alſo been found by the late circumnavigators, in the Society and Friendly iſlands [a]. Dr. Patrick Browne ſays, it is common in Barbadoes and Mountſerrat, where it grows to a conſiderable ſize; but that he had not ſeen it in Jamaica, though he had been credibly informed that it is frequent in the pariſh of Portland. He attributes the whiſtling noiſe to the cups that ſuſtain and partly envelop the nuts; theſe, he adds, are very large, and as they move in the wind, produce ſound enough to alarm unwary travellers. The ſeeds are very oily.

It was cultivated in 1714, by the Dutcheſs of Beaufort [a].

2. Gærtner thus deſcribes the fruit from a ſpecimen in the collection of Sir Joſeph Banks. It is a nut, within the enlarged, membranaceous, inflated calyx; in ſubſtance coriaceous and hard; in form from a ſwelling baſe narrowing upwards like a pitcher; marked with eight prominent ribs, and a convex knob; ending at top in eight ſwellings or riſings; black, ſmooth, not opening by valves. Shell larger than the ſeed, very thick and ſpongy near the knob, in other parts

[a] Linn. mant. [b] Linn. ſuppl.

* Juſſieu genera. [b] Jacquin. [c] Forſter fl. auſtr. [d] Hort. kew.

thin,

thin, ſeparate all round from the ſeed, and filled with a thin cellular ſubſtance. Seed one, large, globular, bony, creſted at top with a flatted rim, or the whole ſurrounded by this rim in manner of a ring; it is ſmoothiſh, of a pale teſtaceous, or reddiſh bay colour. There is no receptacle; but the ſeed coheres by its tip only to the fungous knob of the ſhell; the reſt of it being enveloped in the cellular membrane. The ſeed has two coverings: the outer, cruſtaceous, hard, of a blackiſh cheſnut colour; the inner, membranaceous and ſpongy, buried deep in the clefts of the kernel. There is no albumen, but the embryo is the full ſize of the ſeed, umbilicated at both ends, tomentoſe and inverted: the cotyledons, when ripe, adhere together pertinaciouſly; they divide into four or five larger lobes, and theſe again irregularly into ſeveral other ſmaller ones; they are fleſhy, oily, friable and whitiſh. The radicle is acuminate, very ſmall, placed in the flatted top of the embryo, and ſtretches upwards.

The fruit of the firſt ſpecies agrees with this in every reſpect, except that the ſeed has no ring, and is of a globular form, only a little flatted.

This is a native of the Eaſt-Indies: but has not yet been introduced into culture in Europe.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds in a hot-bed in the ſpring; when the plants are two inches high, tranſplant each into a ſeparate pot, filled with freſh rich earth, and plunged into the hot-bed again, obſerving to water and ſhade them until they have taken root; after which admit air to them, by raiſing the glaſſes, in proportion to the warmth of the air, or the heat of the bed; and water them frequently. As the plants advance, remove them into larger pots, being careful not to break the roots, and to preſerve a good ball of earth to them: if their leaves hang, ſcreen them from the ſun until they have taken new root. Shift them in July, that they may be well rooted before the cold approaches. Keep them conſtantly in the bark-ſtove: in winter give them a moderate ſhare of heat, and in ſummer plenty of air, when the weather is hot. With this management, the plants will grow to the height of ſixteen feet or more; and the leaves being very large will make a beautiful appearance in the ſtove.

4. Herniaria lenticulata.
Lin. ſpec. 317. *Reich.* 616. *Burm. ind.* 78.
Stems ſomewhat ſhrubby; leaves ovate-oblong, hairy.

DESCRIPTIONS, &c.

1, 2. The two firſt ſorts are low trailing plants, extending ſeven or eight inches each way; they have leaves like the ſmaller Chickweed, in the firſt ſmooth, in the ſecond hairy: the flowers come out in cluſters from the ſide of the ſtalks at the joints; they are ſmall, of a yelloviſh green, and make no appearance.

1. [This ſpecies is chiefly diſtinguiſhed from the ſecond by the ſmoothneſs of the habit. The *ſtalks* are trailing and many, forming a little tuft, the length of a finger, or at moſt ſix inches, round, with many alternate branches. *Leaves* ovate or ovate-lanceolate, ſomething like thoſe of wild Thyme, oppoſite, ſeſſile or ſubſeſſile, ſmooth, bright green, quite entire, ſharpiſh at the end, of different ſizes, the larger two lines and an half in length, and above a line in breadth. *Flowers* axillary, glomerate, ſeſſile, ſix or eight together, at the joints of the ſtem and branches, with ſmall ovate-lanceolate, dry, white, ciliate bractes. Calyx often four-parted, ſmall, ſmooth, greeniſh, or yelloviſh green. Filaments very ſhort, and only four in number when the calyx is four-parted; the barren ones more ſlender and whiter than the others. Anthers very ſmall and yellow. Styles two, ſhort, with ſubglobular ſtigmas. *Capſule*, if it may be conſidered as ſuch, membranaceous, compreſſed. *Seed* dark-purple, ſhining, deeply emarginate at the top.—According to Scopoli, the flowers are uſually ſolitary, and on ſhort pedunculeſ*.

It is common in Switzerland, in ſandy ſoils, in Sweden, Denmark, Germany, France, Italy, Carniola; with us in England, at the Lizard Point, Cornwall. Near Newmarket, found by Mr. Hemſted. Flowering in July.

This plant was formerly in ſome reputation not only for curing ruptures, but the ſtone, gravel and dropſy; it was alſo given in diſorders of the eyes. It has now fallen into utter diſuſe. Withering and Pollich ſay, it is ſaltiſh and aſtringent: increaſes the ſecretions by the kidneys; and that the juice takes away ſpecks in the eye. According to Krocker it is agreeable to ſheep.]

Mr. Miller informs us, that the herb-women uſed commonly to bring the Parſley Breakſtone (*Aphanes arvenſis*) to market, inſtead of this plant. [It is of little conſequence which of them is brought; and neither the one nor the other is now much enquired after.

2. Linneus ſeems inclined to think that *Hairy Rupture-wort* is only a variety of the foregoing. Mr. Ray had given the ſame opinion before, and Dr. Stokes follows theſe great judges. Trew alſo has made one ſpecies of them. Pubeſcence is certainly an equivocal ſpecific diſtinction. Haller acknowledges that the habit of this is like that of the foregoing, and that the leaves and bractes are the ſame: he obſerves, however, that it is ſmaller, and that it is eaſily diſtinguiſhed,

* Haller, Scop. Pollich, Leers, Krock.

by the ſmall number of flowers in the glomerules, and by the greater ſize of each. According to Scopoli, this is upright, more branched, and the flowers are ſeſſile, as far as ſix in number together: but Dr. Stokes affirms that they are not more ſeſſile than thoſe of the ſmooth ſort. Pollich adds, that it is of a darker green colour. Whether ſpecifically different or not, it is eaſily known by the whole plant being hairy.

It is native of Germany, Switzerland, Italy, Carniola; and with us has been found by Colney-Hatch near Barnet. It flowers in july and auguſt.]

3. *Shrubby Rupture-wort* has ſtalks trailing on the ground, with ſmall hairy leaves like the ſecond ſort; the flowers are alſo very like that. This is ſhrubby and perennial; [it is a native of Spain.

4. The perianth of this is ſcarcely ſpreading. It has a very ſmall, five-parted corolla. Five capillary filaments. Germ roundiſh, with an obtuſe ſtigma. Capſule one-celled, wrapped up in the calyx. Seed ſubovate, compreſſed. In habit it approaches very near to common Hemaria, but is very ſoft*. Linneus had not ſeen the flowers, but received the character of the fructification from Aymen.—It is a native of the Eaſt-Indies, and the Cape of Good Hope; and is ſaid to have eſtabliſhed itſelf in Spain and the South of France. The plant which has been taken for it in England, ſeems to be only a variety of the ſecond ſort. Plukenet's figure, copied in Petiv. brit. t. 10. f. 6. which is quoted for it, is *Glaux maritima*.]

PROPAGATION AND CULTURE.

1, 2. The two firſt being annual plants, muſt be permitted to ſhed their ſeeds, whereby they are better preſerved than if ſown.

3. The third, being perennial, may be propagated by cuttings.

But as none of them are plants of any beauty, they are rarely preſerved in gardens.

Stem branched, leaves unequally jagged, corolla ſulphur-coloured.]

DESCRIPTIONS, &c.

1. The leaves of this ſort are much larger than thoſe of the Garden Rocket, and of a paler green; the ſtalks are cloſely ſet with briſtly hairs; the flowers grow in looſe panicles at the top of the ſtalk, and appear about the ſame time with the Garden Rocket.

Native of Auſtria and Hungary. Much cultivated abroad for the fragrancy of the flowers in the evening. The ladies in Germany have pots of it placed in their apartments, whence it obtained the name of Dame's-Violet.

[Cultivated here by Mr. Miller in 1739*.]

2. The ſecond ſort grows naturally in Italy; the Garden Rocket with purple flowers was formerly in greater

* Hort. kew.

plenty in the Engliſh gardens than at preſent, having been long neglected becauſe the flowers were ſingle, and made but little appearance: however, as they have a very grateful ſcent, the plant is worthy of a place in every good garden. This riſes with an upright ſtalk a foot and a half high, with ſpear-ſhaped leaves which ſit cloſe to the ſtalk, and are ſlightly indented on their edges, ending in acute points: the flowers are produced in a looſe thyrſe on the top of the ſtalks; the petals are roundiſh and indented at the points, of a deep purple colour, and ſmell very ſweet, eſpecially in the evening or in cloudy weather. It flowers in june, and the ſeeds ripen the latter end of auguſt.

[Mr. Miller is of opinion that the Garden Rocket with white flowers is different from that which bears purple ones, becauſe] the leaves are not ſo long, but much broader, and the borders entire; the flowers not quite ſo large, nor forming ſo good ſpikes, nor having ſo fine a ſcent. [It is however generally agreed that they are not ſpecifically diſtinct. There are double flowers in the gardens of both colours; and having a mixture of both. Mr. Ray obſerved the wild ſingle ſort flowering in the month of june, in the meadows between Salerno and Naples.—This has been known to our gardens much longer than the other, for Gerarde in 1597 ſpeaks of it as being then ſown in gardens for the beauty of the flowers. And Johnſon adds (1633) that by the induſtry of ſome of our floriſts, within theſe two or three years hath been brought unto our knowledge a very beautiful kind of theſe Dame Violets, having very fair double white flowers.—The names in Gerarde are *Damaſk Violets, Winter Gilloflowres, Rogues Gilloflowre*, and *Cloſer Sciences*.—Parkinſon adds *Queen's Gilloflowers*.

β. The habit of the *Siberian Rocket* is ſo much the ſame in all its parts with the common Garden Rocket, that it may fairly be looked upon as a variety. It differs however in having a ſtalk of twice the height; the corolla is purple, not white, and the claws of the petals are twice as long as the calyx; the border is blunt, and ſcarcely, if at all, emarginate; it has however the ſame little prominent point which that has. The leaves are longer, narrower, and more ſerrate. But Siberia produces many plants which are larger than the ſame ſpecies in Europe [a].]

Mr. Miller ſays, it has a ſtrong branching ſtalk between two and three feet high, and very hairy: oblong heart-ſhaped leaves, ending in acute points, ſitting cloſe to the ſtalk, four inches long, and an inch and half broad at their baſe; the upper part of the ſtalk divides into two or three branches, with ſmall leaves of the ſame ſhape with the others, and terminated by looſe panicles of large, ſingle, purple flowers, very fragrant.

It flowered at the end of june 1757.

3. [*Scentleſs Rocket* reſembles the foregoing ſpecies ſo much, as ſcarcely to be diſtinguiſhed except by a ſkilful botaniſt. The leaves however are almoſt haſtate with the baſe tranſverſe; they are finely toothed, eſpecially at the baſe, ſofter, and not ſo ſcabrous. The calyx is not coloured. The petals are blunt, without any point. The ſtamens are not prominent beyond the tube of the flower [b].]

It riſes with an upright ſtalk near two feet high. Leaves dark green ſeſſile. The flowers grow in looſe ſpikes on the top of the ſtalks; in ſome they are white, in others purple, and ſometimes both colours ſtriped in the ſame flower; theſe having no odour, are not ſo deſerving of a place in gardens.

From this ſort, the double white and purple Rockets have been accidently obtained, which are much eſteemed for the beauty of their flowers; and if they had the agreeable odour of the Garden Rocket, they would be ſome of the beſt furniture for the borders of the flower-garden, but they are without ſcent; however, for the beauty of their flowers, they are by ſome greatly eſteemed.

4. [The ſtem, leaves, and pods of this plant are rough with three-barbed hairs. The flowers are fleſh-coloured, with narrow, ſublanceolate, bluntiſh, petals. The pods are ſeſſile, ſtiff, round, ſomewhat flatted, blunt with a ſharp point [c].]

It is an annual plant, with a very branching ſtalk, about nine inches high; terminated by looſe panicles of ſmall purple flowers, which appear in june and july, and are ſucceeded by long pods ſitting cloſe to the ſtalks, and filled with ſmall ſeeds, which ripen in ſeptember. It is a native of Africa.

5. This alſo is an annual plant, ſending out ſeveral heart-ſhaped leaves from the root, which ſpread on the ground. The ſtalk riſes nine inches high, branching towards the top, with leaves of the ſame ſhape, but embracing. The flowers are produced in looſe panicles at the ends of the branches, they are of a lively purple colour, and thoſe plants which riſe in the autumn, flower early in the ſpring. It is a native of the South of France.

[Cultivated in 1739, by Mr. Miller [d].

6. Leaves naked, narrow. Calyxes hairy. Flowers of a dull colour, and unpleaſant ſmell. Pods knotty and three-cuſped [e].]

It is a low annual plant, with pointed leaves, having the borders indented as if torn. The corolla is purple. It is a native of Portugal, [and the South of France: and occurs twice, under this name, and that of Cheiranthus lacerus.

7. Root biennial. The whole plant villoſe with ſhort hairs. Stalks round. Leaves ſeſſile, lanceolate, deeply and unequally toothed, ſoft, and ſubcinereous green. Calyx cylindric, converging, green, a little gibbous at the baſe, the leaflets linear, acute, concave. Corolla ſpread out flat, claws ſcarcely the length of the calyx, border linear, ovate at the end and ſpreading wider, not acute, ſlightly emarginate, without ſcent, greeniſh towards the claws underneath. Anthers ſulphur-coloured, haſtate, two-furrowed. Pods flatted. The peduncles are ſhorter than the calyx and upright; the flowers at firſt form an umbel, but afterwards a raceme. The root-leaves are on a ſhort petiole, ſcarcely equal to half the length of the leaf, convex underneath and flat above. Theſe leaves are firmer than thoſe on the ſtem, ſucculent, ovate, obſcurely and rather angularly toothed.

Native of Piedmont, about *la Briga* and *Soſpello*, on rocks expoſed to the ſun [f].]

PROPAGATION AND CULTURE.

1. This is *propagated by* ſeeds in the ſame manner with the Garden Rocket. It is not quite ſo hardy, and very ſubject to rot in winter, eſpecially in a moiſt ſoil, or in rich land; it ſhould be planted therefore in dry poor ſoil, and a warm ſituation. If ſome plants be ſet in pots, and placed under a common frame in winter, it will be a ſure way to preſerve them.

2. This being biennial, young plants ſhould be raiſed every year to ſupply the place of thoſe which decay: if the ſeeds are permitted to ſcatter, the plants will come up without trouble in the ſpring; and if the ſeeds are ſown, the beſt ſeaſon for it is in the autumn; becauſe thoſe which are ſown in the ſpring often fail if the ſeaſon proves dry, or will remain a long time in the ground before they vegetate. This plant ſhould have a loamy undunged ſoil, in which it will thrive better than in rich land.

There is a variety of this with double flowers, in ſome of the gardens in France; but that which we have in England, is a variety of the third ſort with unſavoury flowers.

3. Being naturally biennial, the plants with ſingle flowers rarely ſurvive the ſecond year; nor will thoſe with double flowers continue much longer; ſo that unleſs young plants are annually raiſed to ſupply the place of the old ones, there will ſoon be a want of them, which is what few perſons are careful enough to obſerve; but thinking the roots to be perennial, truſt to their putting out offſets, or the plants remaining after they have flowered; and finding them decay, are apt to think their ſoil very improper for them, and are at a loſs to account for their decaying; whereas, when the plants have flowered, they have finiſhed their period, and ſeldom continue to flower a ſecond time

[a] Lin. ſpec. [b] Ibid. [c] Linn. ſpec. [d] Hort. kew. [e] Linn. ſyſt. [f] Allioni.

from

from the ſame root; though in poor land, they will often put out a few weak offſets, which may flower again, but ſeldom ſo ſtrong as the principal root; therefore thoſe who are deſirous to propagate theſe plants, ſhould do it in the following manner:

There ſhould be ſome ſtrong roots of each ſort kept apart for this purpoſe, which are not intended to flower; when theſe have ſhot up their flower-ſtalks about ſix inches high, they ſhould be cut cloſe to the bottom; each of theſe may be divided in the middle to make two cuttings, which ſhould be planted in a ſoft, gentle, loamy ſoil, to an eaſt expoſure, where they may have only the morning ſun; and theſe may be planted pretty near together, ſo as to be covered with hand or bell-glaſſes, which ſhould be put over them after the cuttings have been well watered, and cloſely ſhut down drawing the earth round the rim of the glaſſes to exclude the air; then the glaſſes ſhould be ſhaded with mats every day when the ſun is hot; and if the cuttings are gently refreſhed with water once in ſeven or eight days it will be ſufficient, for too much moiſture will cauſe them to rot: when theſe are watered, the glaſſes ſhould be cloſely ſhut down again as before; with this management the cuttings will put out roots in five or ſix weeks, and will begin to ſhoot above; then the glaſſes ſhould be gently raiſed on one ſide to admit the air to them, and ſo gradually harden them to the open air, to prevent their drawing up weak. When theſe have made good roots, they ſhould be carefully removed, and planted in an eaſt border at about eight or nine inches aſunder, obſerving to ſhade and water them till they have taken new root; after which they will require no other care, but to keep them clean from weeds till the autumn, when they may be tranſplanted into the borders of the pleaſure-garden, where they are deſigned to flower.

The roots which are thus cut down, will ſend up more ſtalks than before; and when theſe are of a proper height, they may be cut off and treated in the ſame way; ſo that if the roots are ſound, there may be two or three crops of theſe cuttings taken from them, and by ſo doing, the old roots may be continued much longer than if they are permitted to flower; and by this management, there may be always a ſupply of good plants for the flower-garden.

Theſe plants are very ſubject to canker and rot when they are planted in a light rich ſoil, but in poor ſtrong ground, I have ſeen them thrive and flower in the utmoſt perfection, where the ſtems of flowers have been as large, and the flowers as fair as the fineſt double Stock-gilliflowers. Their ſeaſon of flowering is in the beginning of june, and young plants may be raiſed from the ſtalks after the flowers have decayed, by cutting them in lengths, and planting them in the manner before directed; but theſe ſeldom make ſo good plants as the young cuttings, nor are they ſo certain to grow.

4. This is rarely cultivated, except in botanic gardens. If the ſeeds are permitted to ſcatter, the plants will come up without care, and only require to be kept clean from weeds; or they may be ſown in ſpring or autumn, where they are to ſtand, for they do not bear tranſplanting well.

5. If the ſeeds are ſown in the autumn, they ſucceed much better than in the ſpring.

6. If the ſeeds are ſown in the ſpring upon ſheltered borders, where the plants are to remain, and they are thinned and kept clean from weeds, the plants will flower in july, and produce ripe ſeeds in autumn.

Stem branched, peduncles two-flowered axillary, leaves linear-lanceolate oppoſite entire on the ſtem.]

DESCRIPTION, *&c.*

1. Root perennial, ſending out many cordate-ovate leaves, four or five-lobed, of a lucid green, and ſmooth, from among theſe come out the ſcapes, a foot high, dividing at top into a looſe paniele, ſuſtaining many ſmall hairy flowers, of an obſolete purple colour. It is a native of Virginia; flowers in may, and the ſeeds ripen in auguſt.

[Gærtner remarks, that the capſule may be regarded as of the circumciſed kind; for if it be ſlightly preſſed with the fingers, the horns, together with the partition and lid fall off, leaving the upper margin ſmooth and quite entire.

It appears by the ſupplemental volume to Ray's hiſtory, that it flowered in the Engliſh gardens before 1704.

2. This is a ſpecies which recedes a little in point of the appearance of the flower from the characters of the genus; yet not ſo much ſo as to juſtify the inſtitution of a new genus for it. The whole plant is hairy: the ſtem at firſt proſtrate, then obliquely aſcending; roundiſh, about a palm and half long, with many ſcattering branches towards the baſe; dichotomous above; the leaves are linear-lanceolate, entire, ſharp, pubeſcent, eſpecially at the baſe, oppoſite, ſomewhat ſtem-claſping, an inch and half long, very ſpreading. Peduncle emerging laterally from the boſom of the divarications of the branches, erect, long, dilated at the baſe; two-flowered; with two ſmall pedicels, of which one is longer than the other. Calyx one-leafed, hairy pentagonal, five-parted; the inciſures very ſharp; corolla pentapetalous, yellow; petals erect, ovate. Stamens five, half the length of the corolla; anthers ovate: piſtils two; germ ſingle, ovate: crowned with the diviſions of the calyx. Styles two, ſubulate, divaricated. Stigmas ſomewhat cornered. Pericarp a two-beaked capſule, ovate and two-celled. Seeds many, minute.—Native place uncertain *.]

PROPAGATION AND CULTURE.

1. It is propagated by parting the roots in autumn, and ſhould be planted in a ſhady ſituation. There is little beauty in this plant, but being hardy enough to thrive in the open air in England, it is preſerved in ſome gardens for the ſake of variety.

[HEVEA. See *Siphonia*.]

HIBISCUS. (Ἰβίσκος *of Dioſcorides. Derivation unknown.*)

Lin. gen. n. 846. *Reich.* 911. *Schreb.* 1139. *Cavanill. diſſ.* 3. 143. *Gærtn. t.* 134. *Juſſ.* 273.

Ketmia. *Tournef.* 26.

Solandra. *Murr.* & *Juſſ.*

Claſſ. 16. 6. Monadelphia Polyandria.

Nat. order of *Columnifer æ.—Malvaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* double. *Outer* many-leaved, permanent; *leaflets* linear: more rarely one-leafed, many-cleft.

* Murr.

Inner one-leafed, cup-ſhaped, half-five-cleft, permanent; or five-toothed, deciduous.

COR. *Petals* five, roundiſh-oblong, narrower at the baſe, ſpreading, faſtened at bottom to the tube of the ſtamens.

STAM. *Filaments* very many, united at bottom into a tube, at top (in the apex and ſurface of this) divided and looſe. *Anthers* kidney-form.

PIST. *Germ* roundiſh. *Style* filiform, longer than the ſtamens, five-cleft at top. *Stigmas* headed.

PER. *Capſule* five-celled, five-valved: *partitions* contrary, doubled.

SEEDS ſolitary or ſeveral, ovate-kidney-form.

OBS. Ketmia T. *has the capſule ovate, and ſeveral ſeeds.*

H. pentacarpos *has the capſule globular, and the ſeeds ſolitary.*

H. populneus *has the capſule globular, berried and cloſed; the outer calyx three-leaved and caducous; the inner obſcurely five-toothed, and permanent.*

H. tiliaceus *has the outer calyx one-leafed, crenate.*

H. trionum *has the inner calyx inflated.*

H. micranthus, rigidus, hirtus, phoeniceus *have the ſeeds woolly on all ſides.*

H. ſyriacus *has ſeeds woolly in the circumference. The capſule in ſome is ovate, in others long; the outer calyx is from three to twelve-leaved.*

H. Solandra *has no outer calyx.*

ESSENTIAL CHARACTER.

Cal. double: outer many-leaved. *Capſ.* five-celled, with many ſeeds.

45. Hibiscus bahamensis.
Mill. dict. n. 14.
Leaves oblong-cordate smooth toothletted hoary underneath, with very large flowers.

DESCRIPTIONS, *&c.*

[Much the greater part of the numerous species in this genus are perennials. Many of them have shrubby stalks, but some are only herbaceous. The leaves are alternate, and commonly of a soft texture: in some of the species they are glandulous beneath, especially on the midrib. The flowers are of the Mallow kind, axillary and terminating. The bark in several is capable of being drawn into threads and manufactured for packthread and ropes: and the capsule in some is eatable: others are much esteemed for their ornamental flowers.]

1. Root perennial. Stalk single, two feet high or more. Flowers large, purple.

[It is remarkable in this species, that the flower springs from the petiole of the leaf, as in *Turnera ulmifolia* [a].

The native place of growth is in Virginia and Canada. Cornutus affirms, and from him Ray and Morison, that it came from the woods of Africa; and we are informed by the latter, that it was introduced into the Royal (now no longer Royal) garden at Paris, in 1644.

2. *Marsh Hibiscus* has the habit of the foregoing. The root is perennial. The stems are a foot and half in height, unbranched and annual. The leaves are broad ovate, bluntly serrate, three-nerved, acuminate [b], bright green on their upper side [c], but tomentose on their under. The peduncles come singly from the axils of the upper leaves; they are longer than the petiole, but do not spring from it, support but one flower, and are jointed. The flower is very large [d], and of a bright purple colour [e].—Native of Virginia and Canada, in moist ground [f]. It flowers here in july and august: and was cultivated by Mr. Miller in 1759 [g].

3. Root annual. Stem round, upright simple, a foot in height. Leaves alternate, petioled, without any angles. Flowers minute, on the summit of the stem. Seeds lanuginous.—Native of the East Indies, where it was found by Koenig [h].

4. This is a shrub, with the younger branches, leaves and calyxes rough with stellate hairs. Leaves roundish, serrate from the middle, veinless, five nerved, more hairy underneath. Petioles longer than the leaves. Stipules minute, bristle shaped. Peduncles axillary, solitary, the length of the leaves, jointed towards the top, thicker. Outer calyx ten-leaved, with bristle-shaped leaflets: inner five-leaved, with lanceolate leaflets, shorter than the outer [i].

5. This has the size and appearance of *Alcea rosea*. The herb is tomentose, slightly stinging. Stem herbaceous. Leaves rounded, scarcely lobed, unequally crenate, underneath more tomentose and paler. Peduncles usually longer than the leaf. Flowers axillary, two or three together, subsessile, glomerate. Outer calyx a little shorter than the inner, consisting of ten linear, villose leaflets; the inner angular, thick, villose within and without. Corolla small in proportion to the calyx, purple. Filaments narrow: anthers yellow. Found at the Cape of Good Hope, by Bach [k].

6. This is a beautiful shrub. The leaves are as it were truncate in the middle, crenulate, five-nerved, and soft. The flowers are small and yellow. The capsules small, five together, tubercled with a point. It differs from *H. æthiopicus* (n. 39). in the calyx not being hispid [l].

Native of the Cape of Good Hope. Gathered there by Mr. Fr. Masson, and introduced into the royal garden at Kew in 1774. It flowers from june to august [m].

7. The figure of the leaves in this is the same as in *H. populneus*, without any angles. The calyx as in *H. Malvaviscus* (*Achanta*), but much longer, and having a greater number of leaflets. The flowers rank among the middle-sized ones.—Native of South America, where it was observed by Mutis [n].

8. The twigs long, filiform, quite simple, stiff. The leaves small and petioled. The stipules erect, bristle-shaped, stiff. The peduncles axillary, one-flowered.—Found by Koenig, in grassy spots of the island of Ceylon [o].

9. Stem herbaceous or suffruticose, columnar, hairy all over, supported by trees. Leaves alternate, petioled, cordate without angles, remote. Stipules awl-shaped, minute. Peduncles axillary, the length of the leaves, solitary, pubescent, one flowered. Calyx hirsute: the outer consisting of ten, distant rays, shorter than the inner calyx, spreading at the end into a cordate, obtuse, cowled leaf: the inner bell shaped, larger, angular, five-clefts the clefts ovate. The corolla, stamens, and pistils as in *H. Manihot*. Capsule smooth, hairy, shorter than the calyx. Seeds smooth.—Found at Surinam, by Dahlberg [p].

10. Stem herbaceous, filiform, prostrate, hairy; as is likewise the whole plant. Leaves alternate, petioled, sagittate-cordate, toothed. Peduncles axillary, one-flowered, longer than the petioles. Outer calyx inflated: inner small, five-cleft. Stigmas ten. Capsule half five-grained; with five cells. Seeds very many. This also was found in Surinam by Dahlberg [q].

11. This is a tree, fifteen feet high or more, with a trunk larger than a man can encompass; the wood white and soft; and the bark like that of the Lime-tree: the branches long and spreading. Leaves acuminate, of a soft solid texture, smooth, paler underneath and marked with three strong nerves running from the petiole to the edge; petioles long, round, and slender [r]. Peduncles axillary, solitary, one-flowered [s]. Outer calyx commonly one-leafed, almost quite entire, altogether undivided [t]: but sometimes three-leaved. Corolla large yellowish white, inclining to green, becoming red as it decays; without scent.—Natives of the East Indies, in sandy soils, where it produces flowers plentifully the greatest part of the year [u]. It has also been found in the South Sea Islands; and was introduced into Kew garden in 1770, by Mons. Richard [x].

This cannot be the *Hibiscus populneus* of Miller, which seems to be the first species of *H. mos. hentos*.]

12. This rises with a woody, twisted, pithy stem, from eight or ten [to twelve or fifteen feet in height, smaller than a man may encompass,] dividing into several spreading branches towards the top, which are covered with a brown bark and a woolly down. Leaves alternate, of a lucid green on their upper side, and hoary on their under, full of large veins; [they are broader and rounder than those of the foregoing, of a more solid and thicker texture, and smooth, on petioles of a middling length, underneath like velvet [y]. The younger leaves are subtrilobate, with three pores underneath. The stipules are large and rounded [z]. The flowers are produced towards the upper part of the twigs from the axils, on peduncles an inch long, branched, and supporting several flowers, forming all together loose spikes. In figure and colour they resemble the foregoing, but they are smaller, and roughish on the outside, nor are they so curled and wrinkled; on the lower part of the neck, instead of the five-leaved rose which there is in that, we have a large, round spot of a dusky red purple colour [a]. Both calyxes are one-leafed; the outer cloven half way into ten parts, the clefts alternately larger and smaller; the inner cloven half way into five parts, the clefts equal and the length of the capsule. Capsule ovate, pointed at the top, silky, ten-celled, opening spontaneously in ten parts when ripe: cells close on every side, fissile at the central angle; and five seeds in each [b].

Gærtner agrees with Adanson in the propriety of making a distinct genus of this species, under the name of *Paritii*. Thus there would be no end of dividing every large genus.

Native of the East Indies; and almost every where

within

within the Tropics.—Cultivated by Mr. Miller in 1739[a].

In the iſland of Otaheite they make matting of the bark, as fine as our coarſe cloth. Alſo ropes and lines, from the ſize of an inch to that of a ſmall packthread: and fiſhing nets[b].

In the iſland of Otaheite, as Forſter informs us, they alſo ſuck this bark for food, when the bread fruit fails them: and in New Caledonia the inhabitants frequently ſubſiſt on it, though it is an inſipid food, affording very little nouriſhment.

13. Stem undivided, ſtraight, thickiſh. Leaves bluntiſh, ſmooth with an unequal margin, having a honied pore on the nerves underneath[c].—Linneus informs us that his plant was three years old, and that he had not ſeen the flowers. He aſſigns Aſia for its native place, and yet refers to Sloane. Swartz is of opinion that this is a doubtful plant. See *H. elatus.* (n. 41.)

14. The ſtellate hairs are placed on minute tubercles, towards the tops of the branches they are more crowded, below they are ſcattered. The leaves underneath are more hairy, they are acute at both ends, and the uppermoſt are ſomewhat angular. Stipules briſtle-ſhaped. The leaflets of the outer calyx are lanceolate, nerved, terminated by a briſtle ſhorter than the leaflet: the ſegments of the inner are ovate-acuminate. The flowers have the ſize and appearance of thoſe in H. vitifolius. The cells of the capſule are many-ſeeded, and therefore it is not an Urena. The ſeeds are villoſe[d].

15 The *China Roſe* grows in India to the ſize of an ordinary tree: with us it is ſhrubby, the *ſtem* round, erect, with alternate, ſpreading branches, that are wand-like, leafy, browniſh green and nearly ſmooth. *Leaves* alternate, ſpreading, unequally and coarſely ſerrate, entire at the baſe, five-nerved, bright green, very ſmooth, except the young ones, which are ſlightly downy; their petioles are round, downy on the upper ſide. *Stipules* in pairs, oppoſite, at the baſe of the petioles, linear, acute, deciduous. *Flowers* axillary, ſolitary, peduncled, large, of a deep ſcarlet colour. *Peduncles* twice as long as the petioles, round, ſtraight; thicker towards the top, with a joint beyond the middle. *Calyx* ſmooth: the outer generally in ſix linear acute ſegments, ſpreading; the inner longer, bell-ſhaped, divided half way down into four or five ſegments, angular, ribbed. *Petals* three times as long as the inner calyx, obovate, bluntiſh, waved, furniſhed with ſeveral ribs, paler on the outſide, yellow at the baſe. *Stamens* and *Piſtils* longer than the corolla, bent downwards, red except the anthers which are yellow. *Tube* of the *Filaments* cylindric, with five notches at the top. *Germ* ovate, ſmooth. *Stigmas* five, divaricate, blunt, ſilky, blood-red. The *Fruit* is hitherto unknown.

It is extremely common in the gardens of China and the Eaſt Indies; but its native country is unknown. Loureiro however affirms that it is ſpontaneous as well as cultivated both in China and Cochinchina; and that it is ſo common in the latter, that they have entire hedges of it to their gardens. It has been long known from its appearance on Chineſe ſcreens and paper hangings. The variety with double flowers is moſt frequently cultivated both in the Eaſt and in European hot-houſes: it is indeed rarely ſeen with ſingle ones[e].

Rumphius informs us that it varies with white flowers: but this is not eſteemed, for the inhabitants of India are extremely partial to whatever is red, which they conſider as a colour tending to exhilarate.

Loureiro remarks, that the double-flowered white variety is more difficult to cultivate, and differs a little from the others in having gaſh-ſerrate leaves, approaching in form to thoſe of *H. ſyriacus.* He alſo mentions another variety with large, double, brick-coloured flowers. But in ſo favourite a plant we ſhould not be ſurprized if there were many more varieties.

They make theſe handſome flowers into garlands and feſtoons on all occaſions of feſtivity, and even in their ſepulchral rites. They are put to uſe which ſeems little conſiſtent with their elegance and beauty, that of blacking ſhoes, whence their names of *Roſa calceolariæ,* and Shoe-flower[f]. The women alſo employ them to colour their hair and eyebrows black.

Mr. Miller cultivated it ſo long ſince as the year 1731[g]: but he informs us that he had never had it with ſingle flowers. It is even now rarely ſeen with ſuch in our ſtoves. With double ones it is common, thrives well, and is in blow during the greateſt part of the ſummer. The ſingle flowers are of very ſhort duration, but this defect is compenſated by their curious and beautiful ſtructure[h].

16. Braſilian Hibiſcus is a ſmall ſhrub, with the ſtem, branches, petioles, peduncles, and calyxes all rough with hairs. Stipules awl-ſhaped. Peduncles one-flowered, longer than the leaves. Outer calyx eight-leaved, linear, ſpreading. Capſule pentacoccous, not longer than the inner calyx. It has the appearance of *H. mutabilis:* and is a native of Braſil[i].

17. This is a ſmall plant. The ſtalk, but eſpecially the peduncles, as alſo the leaves and calyxes, are rough with ſtiffiſh hairs. Leaves broad lanceolate, finely ſerrate. Corolla purple. Capſules roundiſh. Seeds woolly.—Native of the Eaſt Indies[k].

Suppoſed, but without reaſon, to be a variety of *H. phœniceus*[l].

18. This is a very beautiful ſhrub; a native of Ceylon. It blows in our ſtoves the whole ſummer, and is very ornamental with its deep red flowers[m]. It is ſet down in Linneus's ſyſtem (edit. 14.) and Supplement, as a variety of the foregoing, ariſing from culture; but it ſeems to be a diſtinct ſpecies.

19. Stem pale, ſingle, ſmooth, ſpreading out wide into leafy branches at top; the wood reſembling that of the Fig. Leaves the ſame ſize with thoſe of the Vine, having the roughneſs of Fig leaves, and the form of both, or rather of the angular leaves of Ivy; whitiſh underneath. Petioles rough, thick, three or four inches in length. Peduncles thicker towards the top, ſometimes tinged with red, ſuſtaining large handſome flowers[n]. Theſe alter in their colour, for at their firſt opening they are white, then they change to a bluſh roſe-colour, and as they decay they turn to a purple. In the Weſt Indies all their alterations happen the ſame day, but in England where the flowers laſt near a week in beauty, the changes are not ſo ſudden. It is a native of the Eaſt Indies (and Japan). The French firſt carried the ſeeds to their ſettlements in the Weſt Indies; and the inhabitants of the Britiſh colonies there, being ſupplied with the ſeeds from them, have given it the name of Martinico Roſe. It varies with double flowers, from which the ſingle is frequently produced; but the ſeeds of the ſingle ſeldom vary to the double.

[It is much cultivated in the gardens of China and Cochinchina.

The time of its blowing in our ſtoves is november and december. It was introduced here in 1690, by Mr. Bentick[o].

20. Outer calyx five-cleft. The capſule has one ſpine at the end, and two on the ſides, approximating to the oppoſite one, ſo that five only appear in the circumference[p].

Native of the Weſt Indies. Introduced in 1778, by William Wright, M. D. It flowers here in july[q].

21. *Maple-leaved Hibiſcus* has the air of *Napæa.* The *root* is annual. The *ſtalk* upright, branched on every ſide, round, hollow, villoſe, herbaceous, a foot and half in height: the branches alternate, ſpreading, round, hirſute. *Leaves* alternate, uſually three-lobed, generally entire at the baſe, the nerves prominent on both ſides; they are villoſe, ſcabrous, bright green, little or nothing paler underneath, ſpreading, three or four inches in length and breadth. The lower ones are ſcarcely three-cuſped; the upper ones of the branches ſinuate-three-lobed, or ſometimes but ſeldom five-lobed. *Petioles* ſpreading, round, hirſute, in the

[a] Hort. kew. [b] Hawkſ. voy. 2. 217. [c] Linn. ſpec. [d] Vahl. [e] Smith ſpicil.

[f] Romph. and Curtis mag. [g] Hort. kew. [h] Curtis mag. [i] Linn. ſpec. [k] Ibid. [l] Retz. obſ. 5. 5. [m] Linn. ſuppl. [n] Ray hiſt. [o] Hort. kew. [p] Linn. ſyſt. [q] Hort. kew.

older leaves the ſame length with the leaf. *Stipules* linear, ſharp, villoſe, ſpreading very much, but ſcarcely reflex. *Racemes* terminating, upright, villoſe, two inches long. *Flowers* alternate, ſtiff, four or five lines wide. *Peduncles* upright, round, villoſe, jointed at the tip, becoming twice or thrice longer when in fruit. *Bractes* two, like the ſtipules, at the ſide of each peduncle. *Perianth* ſingle, one-leafed, half-five-cleft or five-parted, villoſe; ſegments narrow lanceolate ſharp, ſpreading a little, three or four lines in length and breadth. Petals white, blunt, ſpreading a little, united at the baſe, inſerted into the receptacle, longer than the calyx. *Filaments* ſhorter than the corolla. *Anthers* peltate, one-celled, whitiſh. *Germ* ovate, acuminate, marked with lines. *Stigmas* large, pubeſcent, white, cernuous. *Capſule* fixed on the calyx which is preſſed cloſe to it, oblong, acuminate, toruloſe, villoſe; from ſix to eight lines in length, and three or four in breadth. *Seeds* very many, angular, brown, faſtened both to the edges of the partitions and the central receptacle, which is a five-corner column, awl-ſhaped at the top.

Murray has conſtituted a new genus of this, under the name of *Solandra*; but it agrees in the pericarp and all other reſpects with *Hibiſcus*, except in the want of an outer calyx, which is not ſufficient alone to warrant us in ſeparating this from the other ſpecies.

It is a native of Bourbon: where it was found by Commerſon. It was cultivated in the Paris garden before 1775[t]: and was introduced here in 1786, by Mr. Zier. It flowers in july and auguſt[u].]

22. This riſes with a ſhrubby ſtalk to the height of ſix or ſeven feet, ſending out many woody branches, covered with a ſmooth, gray bark; the leaves have the upper part frequently divided into three lobes, are placed alternately on the branches, and ſtand on ſhort foot-ſtalks. The flowers come out from the wings of the ſtalk at every joint of the ſame year's ſhoot; they are large, and ſhaped like thoſe of the Mallow, having five large roundiſh petals, which join at their baſe, ſpreading open at the top in the ſhape of an open bell: theſe appear in auguſt, and if the ſeaſon is not too warm, there will be a ſucceſſion of flowers part of ſeptember; the early flowers are ſucceeded by ſhort capſules; but unleſs the ſeaſon proves warm, they will not ripen in this country.

It is commonly called Althæa frutex by the nurſery gardeners, who propagate the ſhrubs for ſale; there are four or five varieties, which differ in the colour of their flowers; the moſt common has pale purple flowers with dark bottoms; another has bright purple flowers with black bottoms; a third, white flowers with purple bottoms; a fourth, variegated flowers with dark bottoms; and a fifth pale yellow flowers with dark bottoms; but the laſt is very rare at preſent in the Engliſh gardens; there are alſo two with variegated leaves, which are by ſome much eſteemed. [To theſe we may add another, introduced ſince the time of Miller, with double flowers.—It is a native of Syria, and is cultivated in Japan very much for hedges, and in Cochinchina, &c.

The Althea frutex was cultivated in England in 1629, as we learn from Parkinſon[x], and was probably then a new ſhrub, for he ſets it down as tender, and to be kept in a large pot or tub, in the houſe, or in a warm cellar.]

23. This is a native of Ceylon. It riſes with an herbaceous, upright, prickly ſtalk, from two to three feet high, dividing into ſmall branches at top. The flowers come out ſingly from the axils; they hang down, are ſmall, and white with purple bottoms, and are ſucceeded by ſhort obtuſe capſules.

[The prickles of the ſtem are placed on red warts, and are frequently bent back, which is not the caſe in *H. Sabdariffa*[y].

The leaves reſemble thoſe of the Fig-tree, but are ſmaller; they are rough, ſomewhat paler underneath, and have a few hairs; the lower ones are broader and commonly divided into five ſegments; the upper ones narrower and uſually three-lobed. Calyx oblong entire, divided only at the tip into ſmall jags reſembling threads, ſo that when the corolla expands the calyx generally burſt on one ſide. The flowers open only when the ſun ſhines, and that but for a few hours, in the morning, or about noon, they nod or hang down and the petals ſpread irregularly, as in ſome Geraniums. The calyxes, feed-veſſels, &c. have a fine down on them[z].

It flowers from june to auguſt. The ſeeds were ſent from J. Ph. Breynius of Dantzick, to Mr. Miller and Dr. Sherard, and was cultivated by them in the botanic gardens at Cheliſea and Eltham.

24. Perennial. Very nearly allied to *H. Lewis*, deſcribed by Scopoli, in his *Flora Inſubrica*, only the leaves are all five-lobed in this, whereas in Scopoli's plant they are only three-lobed.—It is a native of South Carolina, and was cultivated in 1778, by Dr. Fothergill. It flowers in ſeptember[a].

25. *Root* annual, ſingle, deſcending. *Stalk* herbaceous, from one to three feet high, upright, ſubdivided, round, ſmooth, of a blood red colour. *Leaves* alternate, broad-ovate, acuminate, blunt at the end, crenate, nerved, ſmooth on both ſides, the upper ones three or five-parted, upright. *Petioles* the length of the leaves, ſpreading, round, ſmooth, coloured. *Flowers* axillary, ſolitary, largiſh; on very ſhort, round, thick peduncles. *Outer calyx* has ten linear, awl-ſhaped, upright leaflets, of a dark purple colour: *inner* cup-ſhaped, the clefts broad-lanceolate, ſharp, pale with three purple lines, ciliate at the edge. *Petals* connate at the baſe, obcordate, larger on one ſide, veined, of a very pale ſulphur-colour with a dark blood-red bottom. *Capſule* cloſed by the calyx, ovate. *Seeds* angular, black. Sometimes the leaves are entirely undivided.—The petioles in cultivation are without prickles; probably in their native growth they may be prickly[b]; as deſcribed in *Lin. ſyſt.*

In the Weſt Indies it is called *Red Sorrel*. The calyxes and capſules freed from the ſeeds make very agreeable tarts; and a decoction of them ſweetened and fermented is commonly called there *Sorrel cool drink*. It is a ſmall diluting liquor, much uſed in our ſugar-colonies, and reckoned very refreſhing in thoſe ſultry climates[c].

It is a native of India, and is cultivated in gardens both in the Eaſt and Weſt Indies. Among us it has been long known; being among the plants of Gerard's garden in 1596. It flowers from june to ſeptember[d]. Gerarde laments, that having with great induſtry nouriſhed up ſome plants from the ſeed, and kept them unto the midſt of may, one cold night deſtroyed them all. He and Parkinſon call it *Thorny Mallow*. Ray mentions it as one of the plants which he had ſeen in the garden of Compton Biſhop of London at Fulham.

Mr. Miller makes two ſpecies of this, under the names of *Sabdariffa* and *goſſypefolius*, n. 9. & 10.

26. *Root* annual. *Stalk* five feet high or more, with a few upright prickles ſcattered about it. Branches few, ſimple. *Petioles* ſpreading, the length of the leaves, having ſtraight prickles ſcattered over their backs. The lower *leaves* are undivided and ovate; the middle ones three-lobed; the uppermoſt divided almoſt to the footſtalk into five lanceolate ſegments, theſe have no prickles, but the midrib has a gland at the baſe underneath. *Outer calyx* awl-ſhaped, upright, prickly; *inner* hiſpid, with a gland on each leaflet.] *Flowers* axillary; the corolla large, of a pale ſulphur colour, with a dark purple bottom. [*Capſule* roundiſh, hairy or prickly, covered with the calyx.—It agrees with *H. Sabdariffa* in ſtructure, appearance, ſerratures, and the gland under the leaves[e]. According to Miller, this is a taller plant, and the flowers are larger.

It was cultivated by Mr. Miller in 1759; and is a native of the Eaſt Indies.]

The bark of this and the foregoing ſpecies is full of ſtrong fibres, which the inhabitants of the Malabar coaſt prepare and make into cordage; and it ſeems as if it might be wrought into fine ſtrong thread of any ſize.

[t] L'Heritier. [u] Hort. kew. [x] Parad. 369. n. 7. [y] Linn. ſyſt. [z] Dillen. elth. [a] Hort. kew. [b] Browne jam. [c] Hort. kew. [d] Swartz obſ. [e] Linn. ſpec. and ſyſt.

27. *Stem* round, upright, ſtiff, two feet high, ſpotted with purple towards the top. *Petioles* horizontal, round, the length of the leaves: both they and the ſtem have hairs ſcattered over them, and abundance of crooked prickles underneath. *Leaves* ſpreading, palmate, half-five-cleft: cleſts lanceolate, ſerrate, ſprinkled with little briſtles ariſing from a dot, and having little crooked prickles on the ribs underneath. *Stipules* kidney-ſhaped, ſtem-claſping, ſmooth and even, ciliate. *Pedunculs* prickly, rough with hairs at the tip. *Corolla* yellow with a dark purple baſe. Calyx as it were radiate[a].

Loureiro's deſcription is ſomewhat different, and ſupplies ſeveral particulars not in Linnæus's. It is a *ſhrub* ſix feet in height, climbing, and branched: the ſtem, leaves, petioles, calyx, and peduncles are all prickly. *Leaves* ſome three-lobed, others five-lobed, ſerrate, ſcattered, on long petioles. *Flower* lateral, ſolitary, middle-ſized, on a long peduncle: *corolla* ſaffron-coloured within, and very red on the outſide. Both *calyxes* permanent: *outer* wheel-ſhaped, ten-leaved; leaflets ovate-oblong, pedicelled: *inner* five-cleft; the cleſts ſharp, converging, keeled at the back and on the edge. *Corolla* bell-ſhaped, petals blunt, ſlightly cohering at the baſe. Tube of the *filaments* longer than the calyx: *anthers* oblong, curved inwards. *Germ* conical, five cornered. *Styles* reflex, equal to the ſtamens. *Capſule* a broad cone, without prickles, ſilky; incloſed by the inner converging calyx; and containing many angular ſcabrous ſeeds[b].

Native of the Eaſt Indies, and Cochinchina. It is an annual, and flowers with us in july. Cultivated in 1768, by Mr. Miller[c]: who ſays that the ſeeds were ſent him by Dr. Juſſieu from Paris.

The leaves are gratefully acid, and are eaten. In cataplaſms they aſſiſt in diſſolving hard tumours, &c. for which purpoſe the root is eſteemed to be more efficacious.

28 This was found at the Cape of Good Hope by Thunberg[d].]

29. This ſort riſes with an herbaceous ſmooth ſtalk three or four feet high, with leaves which are divided into ſeven ſegments almoſt to the bottom; the middle ſegment being four inches long and half an inch broad, the upper lateral ſegments about three inches long and the ſame breadth; theſe are indented at their extremities, but the lower ſegments are not much more than an inch long, and have foot-ſtalks four inches long. The flowers are produced from the wings of the ſtalks toward the top, ſtanding on ſhort peduncles; they are compoſed of five large ſulphur-coloured petals, which, when open, ſpread five inches wide; they have a dark purple bottom; and are ſucceeded by large, pyramidal, five-cornered, erect ſeed-veſſels, which are filled with pretty large ſeeds, having little ſmell or taſte.

[In Japan they uſe the mucilage of the root for giving conſiſtence to paper, as Thunberg informs us.

Native of China and Japan. It was cultivated in the Cheſſea garden in 1712; and flowers in auguſt[e].]

30. This ſort grows naturally in the Eaſt Indies; the Society Iſles; and alſo in the Weſt Indies, where it is commonly known by the title of Muſk; the French cultivate theſe plants in their American iſlands, the ſeeds of which are annually ſent to France in great quantities, ſo that they certainly have ſome way of rendering it uſeful, as it ſeems to be a conſiderable branch of trade. This riſes with an herbaceous ſtalk about three or four feet high, ſending out two or three ſide branches, garniſhed with large leaves cut into ſix or ſeven angles, which are acute; they ſtand on long foot-ſtalks, and are placed alternately. The ſtalks and leaves of this are very hairy. The flowers come out from the wings of the ſtalk upon pretty long peduncles, which ſtand erect; they are large, of a ſulphur colour, with dark purple bottoms, and are ſucceeded by pyramidal five-cornered capſules, filled with large ſeeds of a very muſky odour.

[A few of theſe ſeeds are ſufficient to perfume a whole room. They may undoubtedly be uſed in ſcenting powders and pomatums, inſtead of the animal Muſk, which is a ſcarce and dear commodity[f]: and are accordingly put to that uſe abundantly at Paris. In Arabia and Egypt they grind theſe ſeeds, and mix the powder with their coffee, to render it more agreeable to the head and ſtomach.

The officinal names are *Ab-moſchus*, from the Arabic Ab-El-Moſch, which ſignifies grain or ſeed of Muſk; and *Bamia moſchata*. Theſe ſeeds ſeem to have a claim, as a medicine, to the cordial and nervine virtues experienced from moſt other ſubſtances of that claſs[g].

This ſpecies was cultivated among us by John Tradeſcant, jun. in 1656[h].]

31. This riſes with a ſoft herbaceous ſtalk from three to five feet high, dividing at top into many branches. The flowers are axillary, of a pale ſulphur colour with dark purple bottoms, ſmall and of very ſhort duration, opening in the morning with the riſing ſun, but fading long before noon in warm weather. Calyxes of different forms in different varieties: in ſome not thicker than a man's finger, and five or ſix inches long; in others very thick, and not more than two or three inches long; in ſome erect, in others rather inclined.

[The ſtem, according to Loureiro, is ſomewhat ſhrubby, ſix feet high, round, unequal, nearly upright: branches herbaceous, diffuſed, reclining, hiſpid. Leaves crenate, tomentoſe, on long hiſpid, ſcattered petioles. Flower ſolitary. Outer calyx eight-leaved: inner oblong, ſpathaceous, four-toothed at the tip. Capſule oblong, with five ſharp corners. In *Syſt. veg.* the outer calyx is ſaid to be twelve-parted, and to fall with the corolla, except the baſe which continues. The inner is five-toothed. The remarkable circumſtance of its burſting on the ſide is mentioned by both authors.]

This ſort is common in the Weſt Indies, where the inhabitants cultivate it for the capſules, which they gather green to put into their ſoups and pepper-pots.

[They are generally boiled ſeparately, and added juſt before theſe meſſes are taken off the fire: but the ſeeds may be boiled in broth, like barley or any other ingredient, for they are not ſo mucilaginous. The pods, boiled and buttered, make a rich diſh: but they are uſed only in private families in this form. They are full of a nutritive mucilage. It is known in Jamaica by the name of the *Okro* plant. In China and Cochinchina it is cultivated in gardens, for the beauty and colour of the flower, though it is void of ſcent[i]. With us it has been known ſince the year 1692, when it grew in the royal garden at Hampton-court. Here it is annual, and flowers in june and july[k].

32. This is a ſhrub the height of a man and upwards. *Stem* upright, branched, round, pubeſcent. *Branches* ſubdivided, ſtiff, upright, tomentoſe. *Leaves* alternate, acuminate, toothletted, nerved, hirſute and ſomewhat ſcabrous, ſoft-tomentoſe underneath. *Petioles* longer, ſtiff, round, tomentoſe. *Pedunculs* from the terminating axils, upright, thicker than the petioles, ſtiff, long, round, white-tomentoſe, one-flowered. *Corollas* pale, ſometimes duſky yellow[l]. *Calyx*—outer ten-cleft at the baſe; leaflets reflex, hirſute: inner unequal, thick, five-parted; the three hinder parts upright, broad-ovate, acuminate, nerved, wrinkled, rough with hairs. *Petals* unequal; the three hinder ones more erect, the two front ones bent down, united at the baſe, broad-lanceolate, blunt, thick, tomentoſe on the outſide. *Filaments* united above the middle. *Anthers* oblong, ſmall, fulvous. *Germ* hirſute, ovate, depreſſed. *Stigmas* red. *Capſule* large, roundiſh, furrowed, extremely hirſute, with ten blunt angles. *Seeds* roundiſh, large, whitiſh.

It grows, but rarely, in the iſland of Jamaica, in coppices near the coaſt. Its common name there is *Congo Mabee*; the negroes affirming that it came ori-

[a] Linn. ſpec. [b] Linn. ſuppl. [c] Loureiro cochinch. [d] Hort. kew. [e] Hort. kew. [f] Browne jam. who calls it *Muſk Okro*. [g] Lewis's mat. med. *Bamia*. [h] Hort. kew. [i] Loureiro. [k] Hort. kew. [l] Yellowiſh carnation colour, *Sloane*.

ginally from Africa [1]. Sir Hans Sloane says it grows on the Red hills, very plentifully.

33. This is an annual plant. *Stem* upright, round, a foot and half in height, nearly the thickneſs of a finger, green, ſomewhat tomentoſe, rough with a few minute dagger-points. *Leaves* like *Malva ſylveſtris*, cordate, bluntly ſerrate, veined, green on both ſides, ſpreading. *Petioles* round, ſpreading, the length of the leaf. *Stipules* briſtle-ſhaped, ſhort, hairy, ſpreading a little. *Peduncles* axillary, ſolitary, one-flowered, leafleſs, the length of the leaves, drooping before the flowers open. *Calyx*—outer of eight awl-ſhaped, ſpreading leaves. *Corolla* large, yellow with a dark purple baſe. *Stamens* and *piſtil* purple. *Stigmas* dark purple. *Capſule* with five blunt angles, very much flatted, rounded at the tip and ſides [2].

Gærtner deſcribes the capſule as being of the ſubſtance of paper, ruſeſcent, ſubvilloſe, flatted a little; the five angles compreſſed and winged; gaping at the wings. *Seeds* about four in each of the five cells, kidney-ſhaped, powdered with very ſmall raiſed dots, and of a dirty ferruginous colour. Embryo curved, yelloviſh.—Native of the Eaſt Indies.

34. This alſo is an annual plant. *Stem* herbaceous, upright, round, rough with hairs: branches alternate, the lower ones longeſt. *Leaves* alternate, remote, deeply triſid, gaſh-crenate, blunt, gummous-arenaceous underneath. *Petioles* ſpreading, longer than the leaves, flatter above. *Stipules* awl-ſhaped, ſpreading. *Peduncles* ſolitary, axillary (at the ſide of the branchlet), extended ſideways, having a bent joint below the flower. Outer calyx as it were inflated in proportion to the capſule, ovate as in *Atraƈylis cancellata*. *Corolla* fleſh-coloured, the ſize of *Potentilla anſerina*. It differs from the other ſorts in the outer calyx; the flatneſs of the corolla: and in having the five outer ſtamens frequently diſtinct. The capſule is pentacoccous, parting by joints as in *Malva* [3]. In *Fl. zeyl.* it is ſaid to have the ſize and appearance of *Verbaſcum Blattaria*: with a twelve-leaved outer calyx; the leaflets linear and hiſpid.—Native of the iſland of Ceylon.

35. Stem green, upright. Stem-leaves cordate-oblong, finally haſtate, ſomewhat tomentoſe, three-nerved, very finely ſerrate. Peduncles one-flowered, ſolitary, axillary, forming ſomething of a naked raceme at top [4]. It is very nearly related to the next ſpecies, and perhaps only a variety [5].—Native of Virginia, in ſalt marſhes.

36. Root perennial. Stem three feet high, narrow. Stem-leaves cordate-oblong, upper ones haſtate, ſlightly three-nerved, tomentoſe underneath, very finely ſerrate. Peduncles-axillary, on the top of the plant ſolitary, naked, longer than the petiole, one-flowered. Outer calyx ſpreading, with awl-ſhaped rays, ſcarcely the length of the inner. Corolla ſpreading, pale red, nodding a little. The whole of the ſtamens yellow; the anthers of a fuller colour. Style with the ſtamens drooping, white. Stigmas fleſh-coloured [6].—It grows near Venice, in marſhy places: and was found by Lerche near Aſtracan. Cultivated by Mr. Miller in 1759.

Linnæus doubts whether this be really different from the foregoing, though it differs from it a little in the fruit. He ſuſpects that it may owe its origin to that ſpecies [7].

37. The whole of this is hoary with a white pubeſcence. Leaves petioled, elongate, broad-linear, ſome with appendicled lobes at the baſe, others exactly three-lobed, larger, ſmooth. Stipules oblong, quite entire, blunt, large, caducous. Raceme elongate, few-flowered. Bractes in pairs, ſtipule-ſhaped, oblique, at the exit of the pedicels. Calyxes ſimply cleft, without ſpines or appendicle. Capſule globular, ſmooth and even, hoary [8].—Native of the Society Iſles.

38. Stem herbaceous, ſmooth and even, as is the whole plant. Leaves petioled, deeply triſid; clefts ſerrate, lanceolate, the middle one largeſt; the midrib underneath has a glandular pore. Inner calyx five-parted, angular, twice as long as the other; the parts ovate-oblong, upright, edged, ſtiff. Corolla yellow. Capſule ſubglobular, pubeſcent, ſhort.—Native of Surinam. [9]

Swartz ſuſpects it to be the ſame with *Hib. Sabdariffa*.

39. This is a ſmall ſhrub. Leaves alternate, except the uppermoſt, which are oppoſite, on very ſhort petioles, oblong, blunt, three-toothed at the end (ſometimes, but ſeldom five-toothed,) even with very few hairs above, but hiſpid underneath. Stipules acerоſe, ſcarcely longer than the petioles. Flowers pedunculed, ſolitary: the peduncle ſhorter than the leaf. Outer calyx eight or ten-leaved, linear-lanceolate, hiſpid. Petals obovate, the ſize of the Strawberry flower, longer than the ſtamens.—Native of the Cape of Good Hope, where it was obſerved by Koenig [10]. It was introduced into the royal garden at Kew in 1774, by Mr. Francis Maſſon: and flowers here in auguſt [11].

40. It riſes with a branching ſtalk a foot and a half high, having many ſhort ſpines which are ſoft, uſually the leaves are divided into three lobes, which are deeply jagged almoſt to the midrib; theſe jags are oppoſite, and the ſegments are obtuſe: the flowers come out at the joints of the ſtalks upon pretty long peduncles; the outer calyx is compoſed of ten long narrow leaves, which join at their baſe; the inner is of one thin leaf, ſwollen like a bladder, cut into five acute ſegments at the top, having ſeveral longitudinal purple ribs, and is hairy; both theſe are permanent, and incloſe the capſule after the flower is paſt. The flower is compoſed of five obtuſe petals, which ſpread open at the top, and form an open bell-ſhaped flower; theſe have dark purple bottoms, but are of a pale ſulphur colour above [tinged ſometimes partially with pale purple on the outſide, where they are alſo ribbed. The leaves vary in their diviſion, the lower ones being ſometimes almoſt entire, and the uppermoſt next the flower moſt deeply cut, almoſt to the midrib, and the lobes moſt jagged; the two ſide lobes of theſe are ſometimes ſo deeply cut, that it may be ſaid to be a ſubquinquelobate leaf. At the baſe of each peduncle is a pair of long linear bractes. The corolla becomes wholly purple after it has folded up again.

The capſule is ovate, the conſiſtence of paper, puſtuled with protuberances occaſioned by the ſeeds, villoſe, black. The partitions inſerted into the middle of the valves. Receptacle none; the ſeeds fixed in a double row to the central edge of the partitions: there are from eight to twelve in each cell, kidney-ſhaped a little compreſſed, blackiſh-brown ſprinkled with very ſmall callous dots of a cinereous ferruginous colour [12]. According to Scopoli there are only five ſeeds in each cell. The outer calyx is eight-cleft and tuberculed. The corolla on a peduncle longer than the leaf: with ovate acute bractes. Some of the leaves are five-lobed; and the petioles are ſemicolumnar.]

This is an annual plant, growing naturally in ſome parts of Italy and Auſtria. It has been long known in the Engliſh gardens by the title of *Venice Mallow*. Gerarde, (who cultivated it in 1596) and Parkinſon, call it alſo *Mallow* or *flower of an hour*, [and *Good night at noon*, or *Good night at nine*: for Gerarde affirms that it opens about eight of the clock, and ſhuts up again at nine.—On the 16th of auguſt 1796, the day being dry and fine, the thermometer at 66°, the barometer nearly at 30°, ſunſhine and clouds alternately, with a cool gentle breeze at N. E. The plants in a ſouthern expoſure, but open, in the border of a ſhrubbery, the flowers began to open ſoon after eight o'clock in the morning, and were not finally cloſed till after four. Being obſerved every day to the 6th of ſeptember, they continued opening uſually at nine or ſoon after, if the weather was fair. The 31ſt of auguſt being wet, they did not open all day. The 5th of ſeptember being very cloudy, they did not open till half after ten, and were never quite expanded all day. They cloſed from four to half after five, according to the weather; and the afternoon of ſept. 15th, being very fine, they did not cloſe till half after ſix.] The flowers certainly are of

[1] Swartz obſ. [2] Linn. mant. [3] Linn. ſpec. [4] Linn. ſyſt. [5] Linn. ſuppl.

[6] Linn. ſuppl. [7] Linn. mant. [8] Gærtner. [9] H , kew.

ſhort duration, and in hot weather continue but few hours open: however there is a ſucceſſion of them daily for a conſiderable time, in june, july and auguſt.

β. This reſembles the former, but the ſtalks grow more erect, are of a purpliſh colour, and very hairy; the leaves are compoſed of three lobes, which are divided almoſt to the foot-ſtalk; theſe are narrow, the middle lobe ſtretching out more than twice the length of the two ſide lobes, and they are but ſlightly indented on their edges, whereas thoſe of the former are cut almoſt to the midrib; the flowers are larger, and their colour deeper.

[Linneus adds that the ſtalk is more ſimple as well as more upright; that the uppermoſt leaves are five-lobed; and that the peduncles are longer than the petioles. He fancies it to be a daughter of *Hibiſcus Trionum* by *Malva capenſis* [b].]

γ. This alſo has at firſt ſight ſome reſemblance of the others; but it riſes with ſtrong hairy branching ſtalks, with much broader leaves than either of the former, the lower being divided into three, and the upper into five obtuſe lobes, which are crenated on their edges; the flowers are large, but of a paler colour than thoſe.

[Both theſe are natives of the Cape of Good Hope: and were cultivated by Mr. Miller, the latter in 1758.

41. This is a tree growing to a conſiderable ſize. The wood is of a dark olive colour; the bark pretty ſmooth; the trunk tall and ſtraight. The flowers are large and open, not unlike thoſe of the yellow Lily, either in ſize or appearance.

It is reckoned excellent timber. All the tender parts of the tree abound with a delicate mucilage, which may be uſed inſtead of the more common medicines of this tribe [c]. The bark is made into ropes of all ſorts [d].

Native of Jamaica, where it is called *Mahoe* or Mahoe-tree.

42. *Stems* round branched, ſcabrous, three feet high; covered with little, ſharp, divaricating briſtles, growing by threes. *Leaves* alternate, ciliate, ſomewhat ſcabrous, longer than the petioles. *Stipules* awl-ſhaped. *Flowers* very ſmall axillary, ſolitary. *Peduncles* longer than the leaf, upright, jointed and thicker towards the tip. *Calyx* outer of ſix little briſtles, ſcarcely half a line in length: inner a little longer, half-five parted, hairy. *Corolla* whitiſh, villoſe, ſcarcely larger than the calyx: becoming violet-coloured as it withers: petals ovate, never expanding. Tube of the ſtamens very ſhort, not viſible without a glaſs, covered with ovate yellow anthers. *Capſule* globular, the ſize of a pea, ſmooth, with five whitiſh furrows. *Seeds* blackiſh, with a very white wool drawn over them.—In the fruit, pedunckes, and general air it approaches to *H. hirtus* and *phoeniceus*; but among other circumſtances differs from them in the flowers being extremely ſmall, and never opening.—Native of Senegal [e].

43, 44, 45. There are three ſpecies in Miller from the Weſt Indies: which I give as I find them, not knowing whether they are diſtinct from thoſe which are already ſet down or not.]

43. Stem woody, ſeven or eight feet high, ſending out many ſide branches towards the top covered with a whitiſh bark. Leaves about four inches long, and three broad towards their baſe, ending in acute points, and having ſeveral longitudinal veins. Flowers axillary on long pedunckes. Petals roundiſh, yellow turning red as they decay. Capſules large, obtuſe, five-cornered, hairy.—Native of the Weſt Indies.

44. This ſort was diſcovered by the late Dr. Houſtoun in the iſland of Cuba, from whence he ſent me the ſeeds. This riſes with a woody ſtalk twelve or fourteen feet high, ſending out many lateral branches; the flowers come out ſingle from the wings of the leaves; they are of a very bright yellow colour, but not large, and are ſucceeded by ſhort capſules ending in acute points.

45. This has a perennial root but an annual ſtalk. The ſeeds were ſent me from the Bahama iſlands, and ſucceeded in the Chelſea garden, where the plants produced plenty of flowers, but did not ripen their ſeeds. This riſes with ſeveral ſtalks from the root, four feet high, with leaves, *ending in* acute points, of a light green on their upper ſide, but hoary on their under, and ſlightly indented on their edges, ſtanding upon long foot-ſtalks; the flowers are produced at the top of the ſtalks; they are very large, and of a light purple colour with dark bottoms, and are ſucceeded by ſhort capſules.

PROPAGATION AND CULTURE.

[The greater part of this genus of *Hibiſcus* are natives either of the Eaſt or Weſt Indies, and muſt be treated accordingly.

The firſt, ſecond, twenty-ſecond, thirty-fifth, thirty-ſixth, and fortieth are hardy enough to bear the open air in England. But of theſe, the firſt, ſecond, and thirty-fifth; ſeldom flower in the open air here, unleſs the ſummer proves very warm, though the roots will live, if they are planted in a ſheltered ſituation.

The only way to have theſe plants flower in this country, is to keep the roots in pots, and to ſhelter them under a frame in winter, and in the ſpring plunge them into a gentle hot-bed, which will cauſe them to put out their ſtalks early; and when the ſtalks are ſo high as to reach the glaſſes, the pots may be removed into a glaſs-caſe; where, if they are duly ſupplied with water, and have plenty of air in hot weather, they will flower very well in july, and in warm ſeaſons will ripen their ſeeds.

22. *Syrian Hibiſcus*, commonly called *Althæa Frutex*, is propagated by ſeeds, which ſhould be ſown in pots filled with light earth the latter end of march; and if they are plunged into a gentle heat, it will greatly forward the growth of the ſeeds. When the plants are come up, they muſt be inured to the open air, and in may the pots may be plunged into the ground, in a border expoſed to the eaſt, where they may have the morning ſun: the reaſon of my adviſing the pots to be plunged into the ground, is to prevent the earth from drying ſo faſt as it would do when the pots ſtand on the ſurface, ſo that the plants will not require ſo much water in ſummer: theſe plants will require no other culture, but to keep them clean from weeds, and in very dry weather to refreſh them with water during the firſt ſummer, but in autumn it will be proper to remove the pots under a common frame to ſcreen them from the froſt; or where there is not ſuch conveniency, they may be plunged cloſe to a hedge, pale or wall, to a good aſpect: and in ſevere froſt, they ſhould be covered with mats, ſtraw, or other light covering; for although theſe plants, when they have obtained ſtrength, will reſiſt the cold of our winters, yet the young plants, whoſe ſhoots are tender, are very often injured by the firſt froſt of autumn: ſo that if they are not ſcreened the firſt year, they are often killed to the ground. Toward the latter end of march will be a good time to tranſplant theſe plants, at which time a ſpot of light ground muſt be prepared to receive them, which ſhould be divided into beds four feet broad, with paths of two feet broad between; then the plants ſhould be ſhaken out of the pots with the earth about them, and ſeparated with care, for their roots are very tender, and apt to break with little force: theſe ſhould be planted at about nine inches aſunder in the beds; ſo that if four rows are planted in each bed, there will be ſix inches allowed between the outſide rows and the paths. The ground ſhould be gently cloſed about the roots to prevent the air penetrating to them; and if a little old tanners bark, or mulch, is laid over the ſurface of the beds, it will prevent the earth from drying, and be of great uſe to the plants; during the following ſummer they muſt be kept clean from weeds, and if the following winter prove ſevere, it will be prudent to cover the plants again in autumn, eſpecially if they ſhoot late in the ſeaſon, or the autumn prove cold and moiſt, for then the plants will be in great danger of having their tops killed: in theſe beds the plants may remain two years, by which time they will be fit to tranſplant where they are deſigned to remain; for if they are

kept

kept longer in the nurſery, they will not remove ſo well. The beſt time for tranſplanting theſe plants is the end of march, or the beginning of april, for they ſeldom begin to ſhoot till the end of april, or the beginning of may; they ſhould have a light ſoil, not too wet, for in ſtrong land their ſtems grew muſſy, and they never thrive after.

Theſe plants may alſo be propagated by layers; and by cuttings, which, if planted the latter end of march, in pots filled with light earth, and plunged into a gentle heat, will take root; but the plants ſo raiſed, are not ſo good as the ſeedlings. The ſeveral varieties may be increaſed by grafting upon each other, which is the common method of propagating thoſe with ſtriped leaves.

40. This ſort is propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting well; if the ſeeds are ſown in autumn, the plants coming up early in the ſpring, will flower in the ſummer, and thoſe which are ſown early in the ſpring will ſucceed them; ſo that by ſowing them at three different ſeaſons, they may be continued in ſucceſſion till the froſt ſtops them. Theſe require no other culture but to keep them clean from weeds, and thin them where they are too cloſe; and if the ſeeds are permitted to ſcatter, the plants will come up full as well as when ſown, ſo that it will maintain its ſituation unleſs it is weeded out.

[The fifth, ſixth, twenty-fourth, twenty-eighth, and thirty-ninth, require the protection of the Greenhouſe, Cape-ſtove, or Glaſs-caſe. Theſe being natives of the Cape of Good Hope, except the twenty-eighth, which is from South Carolina.

The reſt, being the far greater number, or three-fourths of the whole, muſt be kept in the bark-ſtove, where ſome of them will make a ſplendid figure; particularly the fifteenth and nineteenth.

The principal mode of propagating theſe is by ſeeds,] ſown on a good hot-bed in the ſpring; and the plants afterwards put into pots filled with light earth, and plunged into a freſh hot-bed: treating them afterwards in the ſame way as the Amaranths. The more tender ſorts muſt be plunged in autumn into the tan-bed, there to remain, and to be treated as other tender plants from the Weſt Indies; giving them but little water in winter.

[Several of the ſorts will produce ſeeds here with care in a good hot-houſe; for thoſe which will not, we muſt have recourſe to the countries where they grow naturally. Moſt of them are perennial, and may alſo be propagated by cuttings; particularly the China-Roſe, which is the moſt ornamental of them all.]

42. *H. tiliaceus* will flower the ſecond year, if the plants are brought forward: otherwiſe not before the third or fourth. It will bear the open air in ſummer, in a warm ſituation, but will not make any great progreſs.

49. The plants of this ſort ſhould not be quite expoſed to the open air the firſt ſeaſon, and the firſt winter will require the warmth of a moderate ſtove; but as they get more ſtrength, they may be treated with leſs care, for they will bear the open air in ſummer, in a warm ſheltered ſituation, and will live through the winter in a very good green-houſe, provided they have not too much wet; but the plants thus hardily treated, will not make ſo great progreſs, nor flower ſo well as with a little additional warmth; and if they are too tenderly managed, they will draw up weak, and be leſs likely to flower. This ſort uſually flowers in England in november, ſo that it keeps to the uſual time of flowering in its native country.

49. *H. Manihot* will produce flowers and perfect ſeeds the firſt ſeaſon. The plants may be continued through the winter in a moderate warmth, though few perſons are at the trouble of preſerving the plants after they have ripened their ſeeds, becauſe the young plants make a better appearance.

30. *H. Abelmoſchus* ſeldom lives more than one year in England, though it is biennial in its native country.

31. *H. eſculentus* will live in a warm border, and thrive for a time in a good ſeaſon, but with the firſt cold or bad weather the leaves drop off; it ſeldom flowers, and never perfects ſeeds; ſo that it muſt be ſheltered, at leaſt in bad weather.

36. Though the roots will live in the open ground, yet our ſummers are not warm enough to bring it to flower. The ſeeds therefore ſhould be ſown in a hot-bed, and when the plants are fit to remove, they ſhould each be planted in a ſeparate ſmall pot, and plunged into a moderate hot-bed, allowing them ſufficient air in warm weather. This may ſtand in the open air in ſummer, but will ſeldom flower; to do this it muſt be kept in a deep frame, where it will continue and flower ſeveral years.

Villars dauph. 121. *t.* 29.

H. profunde ſinuatum pubeſcens. *Baub. pin.* 129. *prodr.* 67.

Leaves denſely tomentoſe, curled or ſinuate at the baſe, ſtem ſpreading.

47. Hieracium Liottardi.

Villars dauph. 121. *t.* 29.

Leaves lanceolate, toothed, ſtem upright, two-flowered.

48. Hieracium Jacquini.

Villars dauph. 123. *t.* 28.

H. pumilum. *Jacqu. auſtr. t.* 189. See n. 2.

Leaves pinnatifid at the baſe, hirſute, green, calycine hairs glandular, ſtem with about two flowers.

49. Hieracium lanceolatum.

Villars dauph. 126. *t.* 30.

Stem ſtraight, ſtiff, leaves lanceolate, toothed, flowers in a kind of corymb.

50. Hieracium pulmonarioides.

Villars dauph. 133. *t.* 34. See Allioni n. 792.

Leaves lanceolate, tooth-ſinuate, thoſe on the ſtem ſeſſile, peduncles proliferous.

51. Hieracium albidum.

Villars dauph. 133. *t.* 31. *Hall. helv. n.* 41.

H. intybaceum. *Allion. pedem. n.* 793.

Leaves gnawn, ligulate, biſpid, ſtem ſubdichotomous, few-flowered.

52. Hieracium pappoleucon.

Villars dauph. 134. *t.* 31. *Hall. helv. n.* 40?

H. grandiflorum. *Allion. pedem. n.* 794. *t.* 29. *f.* 2, 3.

Leaves lyrate-ſpatulate, toothed, ſtem leaves with two ears embracing the ſtem on both ſides, ſtem ſtriated, viſcid, few-flowered.

53. Hieracium florentinum.

Allion. pedem. n. 795. *Hall. helv. n.* 54.

Stem branchiate, few-flowered; leaves lanceolate, long-haired; calyxes ſmooth.

54. Hieracium ca pillaceum.

Allion. pedem. n. 779. *t.* 31. *f.* 3. *Baub. prodr.* 21. *p.* 62

Stem almoſt naked, one-flowered, leaves nerved, graſſy, quite entire.

55. Hieracium ſuccifefolium.

Allion. pedem. n. 786. *Hall. helv. n.* 47.

Leaves ſmooth, quite entire, root-leaves elliptic, on long petioles, ſtem-leaves claſping, with blunt hooks.

DESCRIPTIONS, *&c.*

1. *Root* thick, perennial, blackiſh on the outſide, white within. *Stems* round, upright, twice or thrice the length of the leaves, with only one or two ſubſetaceous leaflets on them, and a ſingle flower at the end. *Leaves* all next the root, narrow lanceolate, ſomewhat attenuated at the baſe into the petiole, from two to ſix inches in length, erect, thickiſh, hoary on both ſides, with a cloſe nap of white hairs ſtellate at the tip; the ſtem alſo has the ſame ſort of ſtellate hairs, only ſeſſile. *Calyx* biſpid, with like hairs, aſcending; the ſcales of the calyx are acuminate. Corolla yellow. The *receptacle* is cloathed with very ſhort, villoſe hairs. *Down* ſeſſile and plumoſe. * Native of Auſtria, Carniola, the Palatinate, &c. on mountains; flowering in may, and ripening its ſeeds in june.

2. *Root* perennial, creeping, branched. Stems half a foot in height, generally procumbent and reddiſh. Leaves ovate or ovate-lanceolate, toothed, on a petiole an inch and half in length, which is ſet here and there with ſmall leaves, ſo that the whole approaches to a lyrate leaf. Scapes ſimple, ſuſtaining one flower, or at moſt two, and about the ſame length with the leaves. Calyx cylindric, upright; ſcales in three rows, ovate-lanceolate, about thirteen in number, tomentoſe on the outſide. Corolla pale yellow, broadiſh, with five teeth at the end. Seeds ruſſet, down longer than the ſeeds, ſimple, ſeſſile; the hairs white, and a little toothed. On the Alps, and near the glaciers; in Switzerland, Savoy, Dauphiné, among pebbles and fragments of rocks [b]. This has been mentioned before, under the name of Crepis pygmæa.

3. This ſpecies is principally diſtinguiſhed by the whole of the plant, but eſpecially the calyx, being covered with long white hairs; and the ſcales of the calyx being remarkably looſe.

The root is perennial and fibrous. The root-leaves are many, varying in form from bluntly ovate to ovate-lanceolate; they are moſt frequently entire about the

* Jacquin. [b] Haller. Lin. mant. Allion. Villars.

edge, but ſometimes they are ſlightly toothed: they are always ſprinkled on both ſides with white woolly hairs. The ſtalk is generally about five inches high, with hairs ſcattered over it, which are white except at the baſe, where they are ſuſcous: it is uſually quite naked, or has only a ſmall lanceolate bracte or two at top. It is terminated by one large flower, ſometimes two, ſeldom more. Calyx ſwelling, before it opens globoſe, black, with white hairs ſtanding out. Corolla pale yellow [a]. Seeds oblong, five-cornered, rufous or brown, crowned with a ſimple, ſeſſile, brittle down [b].

Native of Lapland, Switzerland, Dauphiné, Savoy, Carniola, Sileſia, and the mountains both of Wales and Scotland. Flowering in july and auguſt.

4. According to Lightfoot, the leaves are ſometimes pinnatifid or jagged half way down to the rib, which is reddiſh; the petioles alſo red. The ſtalk ſix inches high, ſmooth towards the baſe, but hairy near the top, bearing a ſingle yellow flower. Calyx black, covered with ſuſcous hairs. Seeds crowned with a ſeſſile, *plumoſe* down, which character does not belong to this genus, and therefore Haller has placed it under his genus of *Picris*; Gærtner under *Virea*; Hudſon under that of *Hedypnois*; and it has already been deſcribed under *Apargia Taraxaci*.

Native of the mountains of Switzerland, Scotland and Wales: flowering in july. Perennial.

5. Root-leaves on ſhort petioles, having large teeth about the edge, almoſt linear, broader at the end. Scape entirely ſimple, a ſpan high, naked. Calyx in proportion to the plant, large, ſmooth, formed of unequal ſcales. Corolla ſhort, not large, yellow [c]. Native of Auſtria and Sileſia. Perennial.

6. Shrubby. Stem branched, leafleſs. Leaves radical, marked with blood-red dots and veins. Flowers ſmall, yellow. Native of Virginia and Maryland.

7. *Root* perennial, creeping. Cloſe to the ground come forth barren ſtalks or runners, procumbent, round, leafy, thickly covered with down and hairs: beſides theſe, one ſolitary ſtalk generally ariſes from each plant or off-ſet, from four to ſeven inches or more in height, upright, round, ſimple, naked, hollow, hairy below, and hirſute above, having ſome little ſcales upon it, and ſupporting one flower at the top. *Leaves* on ſhort petioles, ovate or oblong, on the runners lanceolate; perfectly entire, white beneath, with a thick cloſe down, beſides which they have numerous long hairs, each ariſing from a gland; the upper ſurface green, without down, but having many ſcattered hairs, which ariſe alſo from glands. *Flowers* near an inch in diameter. Calyx thick ſet with black hairs, which are globular at the end. Corolla pale yellow or ſulphur colour, compoſed of about fifty florets, the outer having a broad purple ſtripe on the under ſide: each floret has five teeth at the end. *Seeds* oblong, blackiſh, ſtriated; crowned with a ſeſſile, ſimple down, twice the length of the ſeed [d].

It is obſerved by Pollich, that the leaves have frequently teeth round the edge, but ſo ſmall as ſcarcely to be viſible.

Mr. Woodward remarks, that he has never obſerved the Mouſe-ear with more than one flower on a pedunclé: Haller ſays that it has rarely two flowers; but Pollich affirms that it is ſometimes found with two or three. According to Linneus, the flowers commonly open at eight in the morning, and cloſe about two in the afternoon. An inſect of the *Coccus* or *Cochineal* kind is found at its roots [e]; but it has not been obſerved in England [f]. It differs from other milky plants of this claſs, in being leſs bitter, and more aſtringent [g]. On account of this aſtringency it was admitted into the ſhops as a medicine, under the name of *Auricula muris*; but is now little regarded [h].

It is very common in dry paſtures, on ſunny banks, and on walls: flowering from may to ſeptember.

8. In aſcertaining this doubtful plant, it will perhaps be moſt ſatisfactory to give the opinions and deſcriptions of reſpectable writers ſeparately. Linneus only ſays, that the ſtem is rough with hair; that the leaves are the ſame, eſpecially underneath [i]; that it is larger in all its parts than *H. Auricula*, and does not creep [k]. —According to Mr. Hudſon, it has many things in common with *H. Piloſella*, but is larger, and has the leaves hairy, not tomentoſe underneath. The ſcape bears from three to ſix flowers; is from ſix to nine inches high, and ſmooth.—Leers deſcribes it thus. Runners creeping, ſeveral, leafy. Leaves naked underneath, ſomewhat hairy on the upper ſurface, ciliate at the baſe. Scape a ſpan high, ſmooth and even, naked, with a ſingle lanceolate leaflet at the baſe. Umbellar peduncles three or four, ſimple, involucred with as many ſhort bractes. Flowers like thoſe of *H. Piloſella*, nearly equal in height. Corollas pale yellow on both ſides.—Krocker diſtinguiſhes this from *H. Auricula* by the following circumſtances. The number of flowers is fewer, being only two or three; the ſtature leſs; leaves entire, or having very few teeth, more ovate-oblong, (whereas thoſe of *H. Auricula* are lanceolate, longer, and quite entire), having a very few long hairs, in other reſpects ſmooth; they are on very ſhort petioles. Scape upright, a ſpan long, ſomewhat hirſute, frequently tinged with duſky purple, as are alſo the runners: theſe are decumbent and creep, the leaves on them are alternate, and glacous green; but the ſcape is naked, or has at moſt a ſingle leaf or two. Calyx ſwelling at the baſe, ſet with black hairs. Corollas more lemon-coloured. Down white.—Haller gives from five to eight flowers to the ſcape; and Villars ſays there are three or five to ſeven, or even ten.

Mr. Woodward thus deſcribes a plant, which he received and cultivated for the *dubium*, and which he thinks is probably that ſpecies a little varied, though it does not perfectly accord with the ſpecimens either of *dubium* or *Auricula*, as preſerved in the Linnean herbarium.—It differs from *H. Piloſella*, in having leaves oblong wedge-ſhaped, very little concave, hairy on both ſides, but more ſparingly above, grayiſh, but not tomentoſe beneath. The firſt flowering-ſtems ariſe from the ſtolones erect, moſtly two-flowered, rarely one, with equal divaricated fruit-ſtalks. The calyx and fruit-ſtalk cloathed with hairs terminated each by a black globule; the lower part of the ſtem nearly ſmooth. The florets pale yellow on both ſurfaces. Such was its appearance at midſummer; in the autumn, the ſtolones threw out branches which did not root, each again bearing alternate branches, and terminated by a declining ſtem, bearing five or ſix flowers each on a fruit-ſtalk, alternate, ſimilar in every reſpect to the former; at the baſe of each, a lanceolate bracte, and ſimilar ones on the fruit-ſtalks. Seeds oval, ſtriated: feather ſeſſile, with few rays, ſimple, as long as the calyx.

Native of Sweden, Switzerland, Germany, Dauphiné, England, in moiſt places on mountains, as near Rydall in Weſtmoreland. It flowers in july and auguſt.

Sheep are reported to eat this, and yet the foregoing ſpecies is ſaid to injure them. But is it probable that two plants hardly to be diſtinguiſhed, ſhould thus differ in their properties?

9. Root præmorſe, with numerous, ſimple fibres. Runners creeping, leafy. Scape upright, naked, ſcarcely half a foot high, having a few ſcattered hairs on it. Leaves lanceolate, moſtly quite entire, ſharp, naked. Flowers in a panicle, from three to ſix. Leaflets of the calyx linear, hairy [l].—Leaves lanceolate, acute, hiſpid, with very ſmall hairs. The ſtem and calyx have black briſtles ſcattered over them. Being tranſlated into the botanic garden at Upſala in 1742, the year following it grew to the height of three feet, and bore flowers in a ſort of umbel, on long peduncles [m].

Leers deſcribes it thus.—Runners few, creeping, leafy. Leaves broad-lanceolate, ſlightly toothed, dark green, ſcabrous on both ſides. Scape a foot high, the whole muricated with black briſtles; theſe are more crowded at the baſe, above which is a ſingle leaf.

[a] Lin. lapp. & ſuec. Haller, Lightf. [b] Krocker. [c] Scopoli. [d] Curtis lond. Pollich. Woodward MS. [e] Lin. ſuec. [f] Curtis. [g] Withering. [h] Curtis. [i] Syſt. veg. [k] Fl. ſuec. [l] Hudſon. [m] Lin. ſuec.

Flowers terminating, in cymes, crowded. Peduncles five or six, branched, thickiſh, ſhort, having unequal briſtles, black at the baſe, ſcattered over them. Corolla deeper yellow on both ſides. Receptacle ſomewhat hairy. It frequently varies with a ſingle flowering-branch coming out from the middle of the ſcape.

Krocker diſtinguiſhes this from the foregoing ſpecies, by its having a higher ſtalk, and more flowers; longer, narrower leaves, more hirſute, with ſhorter hairs; the flowers ſulphur-coloured; the calyx, like the ſtalk, having black briſtles ſcattered over it.

According to Villars this differs eſſentially from *H. dubium*; for the leaves are glaucous, lanceolate, more hairy; and it has no runners: the ſtalk is about half a foot high, divides into two or three ſpreading branches, each bearing one flower, except the middle one, which has two or three: theſe are larger, and their calyx much more rude than that of the preceding ſort. He can ſcarcely believe that his plant is the ſame with that of Linneus and other authors; but that his is a diſtinct ſpecies, and theirs only a variety.

Haller thinks that this (n. 52.) is ſcarcely a diſtinct ſpecies from *H. dubium* (n. 53.) though it be a higher plant, and bears more flowers. Pollich is of the ſame opinion; ſeeing that this differs only in ſize, having a loftier ſtem, with a greater number of flowers; and the leaves more hirſute, larger, ſharper, and approaching nearer to a lanceolate form.

Native of Lapland, Sweden, Switzerland, Germany, Dauphiné, England, on mountains: as on Dalehead, not far from Graſs-mere, Weſtmoreland. It flowers in july, and is perennial.

10. *Root* præmorſe. *Leaves* longiſh, acute, quite entire, erect, hiſpid on both ſides, with ſtiff hairs. *Scape* a foot high, having fewer hairs ſcattered over it, but they are more crowded towards the bottom; it has a ſingle leaflet above the baſe. *Flowers* almoſt umbelled, but with the pedicels branched; in which circumſtances it differs from *H. præmorſum*: it is diſtinct from *H. Auricula*, in not having the leaves ſmooth on the upper ſurface [1].

Haller has two ſpecies numbered fifty-one; this is the ſecond of them. He deſcribes the leaves as having ſhort hairs, and as being blunt at the end; in number two or three on the ſtalk; which is two feet high, not branched, except the peduncles be conſidered as branches, hirſute all over. Peduncles crowded on the top of the ſtem, branched, hirſute. Flower very ſmall, yellow, with the calyx hirſute, in which it differs from the foregoing n. 51. or *H. præmorſum*.

Leers, who doubts whether his plant be the ſame with Linneus's and Haller's, thus deſcribes it.—*Root* præmorſe. *Runners* none. *Leaves* all next the root, erect, long-lanceolate, ſharpiſh, ſmooth; the upper ſurface and keel ſomewhat hairy; hairs whitiſh, flexuoſe, purple at the baſe. *Scape* a foot and half high, ſtriated, almoſt ſmooth, with a naked, lanceolate leaflet below the middle. *Peduncles* terminating, longer than in the foregoing ſpecies, ſlenderer and more branched, cymoſe during the time of flowering, but afterwards unequal, and forming a ſort of panicle. Flowers the ſame ſize as in *Crepis tectorum*. Calyx whitiſh, with ſhort black briſtles ſcattered over it. Corollas pale yellow on both ſides.

According to Monſ. Villars, this ſpecies is eaſily diſtinguiſhed. The ſtem is ſtraight, about a foot high, terminated by a cyme of flowers ſo cloſe that the peduncles are ſeen with difficulty, though they are branched. Leaves oblong, hairy, reddiſh, rough and entire: the ſtem has one or two at the baſe; it is hairy, and marked with reddiſh glands, from which the hairs take their riſe; the calyx is alſo hairy.—Monſ. Villars doubts whether his plant and Linneus's be the ſame with that of Leers, which he refers to his *H. piloſelloides*. He alſo remarks that Haller has given ſome ſynonyms (as that of Caſp. Bauhin and Columna, whoſe figure repreſents this very well) of the ſpecies under conſideration, to his n. 52., which is *H. Auricula*.—He mentions two varieties; one with red flowers, and another with from three or four to ſix ſcattered flowers, as large again as the common ſort.

[7] Linn. ſpec.

Native of Ruſſia, Denmark, Germany, Switzerland, Dauphiné. Flowering in june. Perennial.—Cultivated by Mr. Miller in 1739 [8].

11. *Root* perennial, fibrous, frequently truncate or præmorſe. All the *leaves* next the root, the firſt obovate, the reſt rather lanceolate, ſharper, ſcabrous, pale green, ſometimes, but very ſeldom having one or two teeth. *Scape* erect, naked, a foot high, ſcabrous, ſtriated. *Flowers* in a panicle containing frequently from ſixteen to twenty. Peduncles naked, having a linear leaflet at their origin, ſpreading, after flowering-time longer than the calyx: the lower ones uſually three-flowered. Calyxes with linear leaflets, not hiſpid. Down a little longer than the calyx [9].

Krocker diſtinguiſhes this from the foregoing ſpecies, by the leaves not being quite entire, but ſomewhat toothed, and alſo broader than in that, being five or ſix inches in length, and an inch, or an inch and half in breadth. The flowers are ſmall, each ſupported on a ſimple pedicel, which has a lanceolate ſtipule at the baſe; forming all together a ſort of ſpike. Stem higher, villoſe, hollow, naked, ſtriated. Roopræmorſe, as in that.

Pollich deſcribes the leaves as ovate, acuminate, very ſlightly ſinuate-toothletted, running down into the petiole, three or four inches long, ſomewhat pubeſcent on both ſides.

The herb watches from ſeven o'clock in the morning to ſix in the evening, when the panicle of flowers alſo nods [10].

Native of Sweden, Germany, Switzerland, Siberia. It flowers in may and june.

12. *Root* perennial, creeping. *Stem* ſcarcely branched (except with the peduncles), bearded with white hairs placed on black glands (according to Haller the hairs are black), upright, a foot or a foot and half in height (two feet high, *Haller*). *Leaves* next the root rather ovate, on the ſtem ovate-lanceolate or lanceolate, quite entire, duſky green, narrowing into the petiole, obtuſe, alternate, the upper ones ſeſſile; the lower ones a ſpan long, and an inch broad. *Stipules* very ſmall, lanceolate. *Flowers* eight or ten, on ſhort pedicels, forming a ſhort panicle. Calyx black, hiſpid; with narrow equal ſcales. Corolla dark red. *Seeds* columnar, furrowed, black; with a white ſimple down [11].

Native of Auſtria, Switzerland, Sileſia, Dauphiné, Piedmont, and Scotland. It flowers from june to autumn. It varies much in the colour of the flower, from red to orange, and ſeveral ſhades of yellow. It is called by our old writers *Golden Mouſe-ear*; and, when of a dark colour, *Grim the Collier*.—Cultivated by Mr. Miller in 1739 [12].

13. This approaches very near to the Hieracium figured by Dillenius; (*elth. t.* 149. *f.* 179.) but it differs, in having the leaves more blunt, thoſe next the root almoſt ſeſſile, ſcarcely toothed; the ſtem more erect and ſlender, hairy only at bottom, and the leaves only half the ſize. The few leaves that there are on the ſtem are ovate and embracing [13]. Native of Virginia.

14. Root-leaves on long petioles, an inch in length, reckoning the petioles, three inches and more, half an inch in breadth, ending in a ſhort point. Stems a long ſpan in height, round, firm, upright, undivided for two thirds of the length, then dividing into ſubbirſute branches of various lengths, forming a ſort of umbel. At the origin of each branch there are ſhort and very narrow ſtipules, and the peduncles have a ſcale or two of the ſame ſort. Each branch is either ſimple, or divided into two or three peduncles, from an inch to two inches in length, hirſute, and all terminated by a yellow middle-ſized flower. Calyx ſimple, ſcales eight or ten, hirſute, with blackiſh hairs, and ſome ſhort little ſcales at the baſe. Native of Siberia: found by Steller [14].

15. *Root* thick, long, like Navews, with one or two branches. Leaves next the root two or three inches long, reſembling thoſe of *Barbarea*, *Lapſana*, and

[8] Hort. kew. [9] Linn. fl. ſuec. [10] Ibid.
[11] Krocker, Haller. [12] Hort. kew. [13] Gronovius.
[14] Gmelin.

Crepis tectorum, runcinate or lyrate, with from five to seven small, obtusely triangular pinnules on each side, almost opposite, scabrous and rough, with hairs on both sides; other very small pinnules are frequently interposed; the extreme pinnule is near an inch long, cordate-hastate or ovate, angular, with larger teeth, as in *Alliaria*, *Cacalia*, &c. Scapes lasless, coloured, one to six, from a palm to a foot or eighteen inches in height, hispid with spreading hairs, usually more hirsute towards the top, at first bowed towards the ground, then erect. Branches or peduncles very hairy, alternate, but near to each other, an inch or two in length, one-flowered; from the top they come out three together. Calyxes calycled like *Crepis pulchra*; the lower or outer scales very small, ovate, acute; the inner calyx consists of equal, lanceolate-oblong, acute, smooth scales, membranaceous and white at the edge. Corollas yellow, the size of *Crepis foetida* and *tectorum*. The marginal seeds are thicker, shorter, winged, bowed inwards, with the edges a little revolute, the dorsal nerve green, and each rolled up in a scale of the calyx, as in *Caltha*, *Rhagadiolus*, and *Hyoseris*; these have no down. The central seeds are narrow, longer, straight; and have a hairy, sessile down.—It differs much from *Hypochoeris*, in having naked, but not scaly peduncles; from *Hieracium* in having a calycled, not an imbricate calyx. Hence Gouan has inserted it in the genus *Crepis*.

Native of Palestine, the South of France, and the County of Nice [a].

16. Scape a foot high, even, with a few, very small, awl-shaped leaves alternately scattered over it. Flower terminating, from the axil of the leaves. Native of the Cape of Good Hope [b].

17. Root perennial, single, deep, blackish. Stem single, undivided, straight, from a foot to two and even three feet in height, in a fertile soil. Stem-leaves decreasing in size up to the flower, the uppermost being nothing more than a scale; the others surround the stem with their rounded base, and end in a lengthened point. Ray says, that the leaves resemble those of Endive, but are narrower, that they are a span long, smooth and sinuated.—Flower large. Calyx very villose and ruffet. Corolla yellow. Seeds seperated by silky threads, of the same length with themselves [c].

Linneus had made it a *Hypochoeris*, but the receptacle having no chaffs, it has been removed into this genus [d]. Mons. Villars makes it an *Andryala*, on account of the silky hairs upon the receptacle.

Native of the mountains of Savoy and Dauphiné, in pastures.

18. Stem a foot high, round, woolly-white at bottom, smooth at top. Leaves broadish, attenuated at the base, acuminate, remotely toothed, tender, smooth; the lower ones hairy underneath, especially along the keel. Panicle terminating, variously branched, with very slender, divaricating peduncles. Bractes at the ramifications very short, bristle-shaped. Flowers small. Observed in Canada by Kalm [e].

19. Stem a foot high, round, almost naked, having only a single leaf or two on it, and very few leafless branches. Root-leaves lanceolate, upright, with one or two sharp teeth, even, having a few villose hairs along the keel: stem leaves minute, very few. Calyx imbricate, hoary, oblong. Corolla yellow, not one of the largest [f]. The whole plant, according to Villars, has the smell of the wild lettuce, in a greater degree than any of the Hawkweeds.

Native of the South of France, the Valais, Austria, Silesia, Italy. Perennial. Introduced by Doctors Pitcairn and Fothergill in 1775 [g].

20. Stem a span high, even. Root-leaves petioled, smooth: stem-leaves five or six, alternate, long, with long recurved teeth, like those of Leontodon autumnale (Apargia autumnalis). Peduncles from the upper axils of the leaves, the same height with the stem, solitary, almost naked, one-flowered. Bractes one or two, bristle-shaped, subvillose at top. Calyxes black, hispid, upright, imbricate, with linear leaflets. Corolla yellow [h].

Native of the South of France, Austria and Silesia: flowering in june and july. Cultivated in 1640 [i].

21. This plant varies exceedingly, as appears from the different figures which are given of it. The general appearance is as follows:—Root simple, producing one slender stem, a foot or fifteen inches high, cylindrical, having soft hairs scattered over it, slightly striated, reddish towards the base; sometimes naked, or nearly so, sometimes cloathed with leaves similar to the others, only more acute. The root-leaves vary considerably, but the most usual form is oval-lanceolate, pointed at both ends, and marked with a few large teeth towards the base, entire upwards, hairy on both surfaces, but the foot-stalk and midrib most so. Flowers in a branched panicle on separate peduncles, with each an awl-shaped bractle. Calyx of numerous, unequal, linear-lanceolate leaves; the lower ones spreading. Corolla yellow. Seeds nearly cylindrical, furrowed, smooth, dark purple, crowned with a sessile down, as long as the seed; rays simple, the length of the calyx [k].

Linneus observes, that the flowers open about six in the morning, and close about two in the afternoon. Lightfoot informs us, that about eighteen days elapse between the first expansion of the flower and the ripening of the seed.

It is a perennial plant, is found in woods, on old walls, on shady banks, &c. and flowers in june and july, sometimes in may. By our old authors it is called *French* or *Golden Langwort*.

β. In this variety, which is made a distinct species by Gouan and Villars, the root-leaves are narrower, and more slightly toothed. Stem-leaves several [l].—Villars says, that it grows to the height of three or four feet; that the stems are straight, leafy, and terminate in several branches: that the leaves are oblong, lanceolate, often toothed, dusky green, a little ash-coloured, and soft to the touch. The peduncles have two scales next the calyx, as in the common plant, but the calyx is larger; the seeds oblong, channelled, very dark purple, shorter than in the other sorts, very like those of *H. fabaudum*, which bears much resemblance to this plant in other respects. The egret or down is short, yellowish white or brown, brittle and straight.

Retzius describes a plant which he takes to be the same with this, as having the root almost praemorse, and seeming to consist wholly of fibres; several stems, which are leafy, hairy, and many-flowered; root-leaves petioled, ovate-lanceolate, either entire or toothletted, hairy, especially at the edges and along the nerve, running down into very hairy petioles, which are dilated at the base; stem-leaves lanceolate and sessile; bractes awl-shaped at the base of the peduncles, and on the peduncles themselves; flowers smaller and paler than in the common sort.

Johnson relates, that it was found by Mr. William Coote, in the old Roman camp at Sidmonton near Newberry [m]. This appears to be a variety of Cineraria integrifolia. See *Smith, in Lin. trans.* 9. 238.

γ. With very narrow leaves, on rocks by the rivulet between Shap and Anna well in Westmoreland [n].

δ. With roundish-ovate leaves; thus described by Mr. Woodward. Root thick, woody, running deep among loose stones, terminating in long dark brown fibres of the thickness of packthread. Root-leaves on hairy foot-stalks, obtusely oval, obscurely toothed, with a few hairs on the upper, and many on the lower surface, spotted with numerous dark-red spots. Stem about six inches high, naked, bearing one flower on the summit, and two imperfect sessile ones a small way beneath it: under the lowest are two awl-shaped bractes. The lower part of the stem is slightly hairy, the upper part and calyx more so. He gathered this elegant variety on Conzick Scar, near Kendal in Westmoreland: and it has been found at several other places in the north. Lightfoot mentions five varieties:

1. With leaves sprinkled with white spots; which

[n] Ray syn.

Ray found frequently abroad, and in the woods near Cuckfield in Suſſex [a].

2. With narrower and more lanceolate leaves: probably our [γ].

3. With radical leaves roundiſh: our [δ].

4. With leaves pinnatifid at the baſe.

5. With naked unbranched ſtalks, bearing two, and ſometimes only one ſingle flower. Frequent upon the highland mountains in dry rocky places. Figured by Petiver, *herb. brit. t.* 11. *f.* 4.

22. Murray ſays, that Profeſſor Jacquin has allowed this to be different from H. pumilum, n. 2.

23. Root perennial. Stem from one to two feet high, hollow, furrowed, ſmooth, generally bright purple at the baſe. Leaves alternate; the lower petioled, oval-lanceolate; the upper ſtem-claſping, lanceolate, deeply toothed towards the baſe, entire at the ſummit; the uppermoſt entire; all ſmooth; the foot-ſtalks and midrib of the lower leaves ſometimes purple as the ſtem, particularly on the under ſurface. Flowers ſingle, ſmaller than in *H. murorum*. Leaves of the calyx linear-lanceolate, covered on the back with numerous black hairs. Peduncles ſmooth [b].

The flowers open at ſix in the morning, and cloſe at five in the afternoon. Poſſibly it may be only a variety of *H. murorum*, though it has acquired, from its place of growth, ſo very different an appearance [c].

Native of many parts of Europe, in moiſt meadows and woods, and by the ſides of mountains, rivers and rivulets. With us in ſeveral parts of the northern counties of England, and in Scotland.

24. This is very nearly allied to the foregoing. Stem even. Calyxes pubeſcent, as are alſo the peduncles, which is not the caſe in that. Leaves more lyrate, petioled, with blunter angles. Native of Siberia [d]. Introduced in 1777, by Monſ. Thouin [e].

25. Root perennial, black, branched, frequently ending abruptly. Plant evergreen. Stem eighteen inches high, branched at top, bearded at the baſe only, or between the ſheaths of the root-leaves, with long white hairs, cloſely crowded together, in other parts quite ſmooth, glaucous, ſhining, ſlightly ſtriated. Leaves thin; the bottom ones of various ſizes, from three inches to a foot in length, from an inch and half to two inches in breadth, ſeldom ſharp, narrowing into the petiole and decurrent, with a few very ſmall teeth from the baſe only to the middle, thence always quite entire to the end; the younger ones are greener, only with white hairs underneath; thoſe which are more advanced are quite bald, except at the baſe of the petioles and along the midrib, of a yellowiſh green, or glaucous. Stem-leaves oblong-ovate, broader at the baſe; the uppermoſt and thoſe on the branches are more cordate and ſharper. Corymbed, alternate, many-flowered branches ſpring forth about the middle and upper part of the ſtem. Peduncles one-flowered, aſh-coloured, and hiſpid, with long hairs, ſingle from the axils, with a ſcale about the middle of them. Calyxes acute, ſcarcely pubeſcent at flowering time [f].

Linneus refers to Tournefort, and Monſ. Villars ſays, that Tournefort's plant, which he had ſeen in the Paris garden, has a ſtrong, branching ſtem; cordate, villoſe, glaucous, toothed leaves; and large flowers: ſo that it is between the *H. villoſum* and his *ſcorzoneræfolium*. He adds, that Linneus's plant, in its pointed leaves, villoſe and glaucous on both ſides, its large flowers, and its calyx, approaches to his *H. villoſum*: and that Gouan's, in the multitude and ſmallneſs of the flowers, approaches rather to his *H. prenanthoides*.

Gouan remarks, that it varies in its native place, with a ſtem ſcarcely a hand in height, with two flowers, and a ſingle leaf, if any. Native of the Pyrenees, and Scotland. Cultivated in 1739, by Mr. Miller [g].

26. Allied to *H. villoſum*, and ſtill more to *pyrenaicum*. The whole plant has hairs glandular at the tip, thinly ſcattered over it. Stem a foot high, ſtriated: branches uſually two-flowered from the upper axils. Leaves cordate (the lower ones oblong) green on both ſides, finely toothed. The panicle has a pile between the hairs, by which it is almoſt tomentoſe [h].

Native of the Pyrenean mountains. Cultivated in 1739 by Mr. Miller [i].

Gouan, who makes the next a variety of this, ſays that no ſpecies varies more, but that it may eaſily be diſtinguiſhed by its pleaſant balſamic ſmell whilſt young, and by the whole plant abounding in glutinous hairs, having globules at the end.

According to Villars, the conſtant characters of the ſpecies in all the varieties are, the great quantity of glandular hairs, which give it the ſmell of baum or new honey; the openneſs of the lower ſcales of the calyx; the ruſſet colour of the whole plant; the truncated root; and the hairs of the egret brittle, and elbowed at the baſe.

27. This ſpecies alſo varies ſo much as not eaſily to be determined. It partakes of this genus, Crepis and Picris; and ſeems very nearly allied to *Crepis ſibirica* [k]. Which however differs from this totally, according to Monſ. Villars: the ſtem being ſingle in Cr. ſibirica, four feet high, terminated by ſeveral ſpreading branches, the ſide ones higher than thoſe of the middle, as in Crepis biennis; the leaves three times as wide and longer, almoſt ſmooth, dark green above, the form and colour of turnep leaves; the ſtem-leaves cut, lyrate at the baſe, the upper ones linear; the calyx not double, angular, dark, with black hairs, that have no glands at the end. Seeds oblong, with a white ſeſſile egret.

α. Root perennial, fibrous, forming a tuft, whence ſpring ſeveral ſtems, a foot and half high. Leaves more or leſs villoſe; the lower oblong and toothed at their baſe; thoſe on the ſtem ſhorter and claſping. Peduncles ſeveral, ſolitary, from the upper axils, each terminated by one large, yellow flower, in which the florets are ſeparated and diſperſed. Calyx double; ſcales of the outer linear, of the ſame height with the others, but leſs villoſe; the inner black, ciliated on the back, and ſometimes glandular. Seeds long, with a white ſeſſile egret. Receptacle a little villoſe. Native of Dauphiné [l].

β. Root as in *Hypochæris radicata*. Stem two feet high, upright, ſlightly ſtriated, hairy, branched only at top; branches naked, alternate, one-flowered, forming a ſort of corymb. Leaves hiſpid on both ſides, with hairs ſtanding out; the lower ones three inches long, lanceolate, an inch broad, acuminate, narrowing at the baſe into the petiole, half-ſtem-claſping, toothed; the ſegments alſo ſometimes toothed. Stem-leaves ſeſſile, broader at the baſe, half-ſtem-claſping. Peduncles or branches three inches long, axillary, alternate, cloathed at top only with very ſmall, looſe, wandering ſcales. Calyx ovate, with the outer ſcales looſe and very ſmall; the inner twice as long; all hairy on the dorſal nerve. Coroll a yellow. Down feathered, ſeſſile.—In appearance it very much reſembles *Picris hieracioides*; from which however it differs in having alternate, long, one-flowered peduncles; larger hairy calyxes, not hiſpid; and the teeth of the leaves ſpreading.—Native of the Pyrenean mountains [m].

γ. From a woody, perennial, brown, divided root, ariſe a few, ſimple, round, ſmooth, upright ſtalks, ſtriated, and more or leſs hiſpid at top, annual, from a foot to a foot and half in height. Root-leaves very few, obverſely lanceolate, toothletted, narrowing gradually into a long petiole: on the flowering plant there are commonly none of theſe. Stem-leaves alternate at certain intervals, lanceolate or ovate-oblong, acute, toothletted, not ſinuate, ſtem-claſping, very ſlightly hirſute, the longeſt four inches in length, thin. Peduncles three or four, ſometimes only a ſingle terminating one) axillary, ſolitary, almoſt of the ſame height, upright, hiſpid, ſtriated, leafleſs, or having only one or two ciliate bractes. Flower large and elegant, yellow. Calyx hiſpid, with long briſtles; leaflets very many, oval, acuminate, black, almoſt equal; the outer ones very looſe. Seeds oblong, crowned with a white, ſeſſile, ſimple down. It is therefore very nearly allied to *Crepis ſibirica*, differing from it principally

in

in the leaves.—Native of Auſtria, flowering there in auguſt [c].

2. In habit this differs not much from *Picris pyrenaica* and *hieracioides*, but it does abundantly in having all the leaves minutely toothed. Stem-leaves much ſagittate, with very acute earlets. Peduncles long, one-flowered, ſwelling below the flower, black with hairs, without any ſuch wandering ſcalelets as there are in Pycris pyrenaica. Calyxes ovate, with black hairs all over them, not at the angles only, imbricate with looſe ſcales. Down ſimple, ſeſſile [d].

Native of Switzerland, &c.

28. Root perennial, blackiſh, bitten, and furniſhed with long white round fibres: it produces annually a ſimple, upright, ſtriated, purpliſh, ſomewhat hairy, leafy ſtem, of about a foot or two in height; the top of which is divided into a few ſingle-flowered or two-flowered foot-ſtalks, of about an inch and half long, and a little hairy. The leaves are oval, obtuſe, quite entire, villoſe on both ſides, and ſoft. The upper ones are ſeſſile; the loweſt and radical ones a little narrowed into a foot-ſtalk either ſimple or ſubmarginated: in ſome individuals theſe leaves are a little toothed; and again in others lanceolate, and that either obtuſely or acutely; ſo as to differ a little from the more common appearance. The calyx is oblong, and conſiſts of leaflets diſpoſed in a ſingle ſeries, not imbricated, nearly equal, ſharp, erect, concave, blackiſh-green, and hairy. At the baſe commonly ſtands a little ſcale or two, ſcarce obſervable. Corolla deep yellow, with anthers and ſtigma of the ſame color. Seeds ſtriated, ruſeſcent, crowned with a ſeſſile down, which appears toothed when magnified: the other particulars agree with the Linnean character. It grows about the borders of the ſubalpine woods, flowering in july, and producing ſeeds in auguſt. It approaches neareſt to the Hieracium murorum, with which it often grows mixed; but is truly different, and even diſtinguiſhable at a diſtance by the number of leaves on the ſtem, and the colour of the flowers. When cultivated in a garden, it flowers about the end of may and beginning of june, and grows more branchy from the boſoms of the leaves; but in other reſpects does not change its habit. —Native of Auſtria. Was diſcovered alſo in Scotland in the year 1780 by Mr. Dickſon.

29. This plant grows a foot high or higher, on hilly meadows; flowering in june, and ſeeding in july. From a perennial, bitten, oblique, round root of about the length of an inch and a half, and the thickneſs of a quill, of a paleiſh brown colour, and increaſed by ſmall fibres, it produces annually a ſolitary, round, ſomewhat ſtriated, fiſtulous ſtem, ſmooth below, and above rather hiſpid, with ſcattered dark hairs: it is either furniſhed with one leaf, or elſe is quite aphyllous, and divided into two, three, or four ſingle-flowered foot-ſtalks, which are upright, and have each a ſmall leaf or ſtipule beneath. The radical leaves are few, and are gradually attenuated and lengthened downward (or into the foot-ſtalk) from an obverſe-ovate and rather mucronated ſhape: they are thin, very ſmooth on both ſides, ſparingly dentated, and of a bright green, with pale green backs. The cauline leaf, when preſent, is oblong-lanceolate, ſeſſile, ſharp-pointed, ſomewhat dented, and according to the different height of its inſertion is ſometimes quite ſmooth, and ſometimes hiſpid, like the ſtem. The calyx is nearly equal, and blackiſh green; with ſharp ſcales, thickly haired with black hairs. The corollules are yellow and five-toothed. Anthers brown. The calyx is reflected when in ſeed. Receptacle naked, punctated, and flat; ſuſtaining oblong, obtuſe, browniſh, ſubmuricated, oblong ſeeds, crowned with the pentaphyllous calyx, and with a ſimple ſtipitated down. It has moſt particulars common to moſt of its congeners: it recedes from Hieracium in the foot-ſtalk of the down; ſo that it might ſeem to conſtitute a ſingular genus [e].

Native of Auſtria.

30. Stem ſtriated, ſomewhat hairy. Branches the height of the ſtem. Root-leaves lanceolate, broadiſh, ſomewhat hairy, with unarmed teeth. Stem-leaves cordate, claſping, converging upwards at the baſe. Peduncles one-flowered, with a remoter calycine bracte. Calyx ſpreading, leſs imbricated, with leaflets nearly equal in length, and hairs black at the baſe, and a yellow gland at the top ſcattered over them. Seeds black, with a ſeſſile, ſimple down [f].

It varies, ſays Jacquin, ſo much in different ſoils, that it is difficult to give ſuch a deſcription as will agree with every individual.—Root knobbed, unequal, blackiſh, perennial, with round, whitiſh fibres. Stem upright, round, hairy, about half a foot in height, greeniſh-aſh-colour, often dotted with brown; it has few leaves on it, and is commonly quite ſimple, terminated only by a ſingle flower, with ſometimes, but very ſeldom another peduncle or two from the upper axils. Root-leaves few: ſtem-leaves alternate, nearer the lower, they are pale green, ſomewhat toothed, acute, ſeſſile, having long white hairs, eſpecially on the midrib and along the edges; the lower ones oblong, attenuated at the baſe; the middle ones ſubovate; the uppermoſt ſubcordate: ſometimes theſe are waved, but they are more often flat. The points of the leaves are brown. Flower large, handſome, yellow. Calyx looſe, with black dots, and much white wool [g]. Seeds ſhort, with a ſeſſile, ſimple egret, appearing toothed with a magnifier.

The hairs on this plant are almoſt all very white, long and feathery; there are ſome, however, ſhorter, and terminated by a gland [h].

Native of Dauphiné, Switzerland, Auſtria, Bohemia, Sileſia, in mountain paſtures. Found alſo on moiſt rocks on Ben Nevis mountain in Scotland by Mr. James Dickſon, in 1789, and at the foot of Ingleborough in Yorkſhire, by Mr. Caley.

β. Stem ſimple, terminated by one or two flowers, higher by half than that juſt deſcribed. Scales of the calyx not open. The whole plant leſs white, more ruſſet; and the long feathered hairs, which are almoſt the only ones in that, are in this mixed with other ſingle ones, that are ſhorter and glandular, and alſo with a third ſort, very fine, branched and ſeſſile, making the calyx farinaceous [i]. Native of Dauphiné, Switzerland, &c.

γ. Stem ſtraight, eighteen inches high, with long hairs at bottom, otherwiſe ſmooth, one-flowered. Root-leaves half a foot long, lanceolate, leſs than an inch in breadth, ſmooth, except that ſometimes the midrib has very long hairs on it; they are tender, and either entire on the edge, or with a very few ſhort teeth. Stem-leaves ſeveral, oval-lanceolate, half-ſtem-claſping, not hooked. Flower large, yellow; the calyx bearded with fulvous hairs, which become hoary. Native of Switzerland [k].

δ. Jacquin mentions his having found a variety of this, in moiſt meadows, and in a lower ſituation, which was quite ſmooth and glaucous, or had very few hairs on it, which was probably the ſame with this of Seguiers.

31. This has the habit of *Crepis teſtorum*. Leaves ſoft, clammy; the upper ones lanceolate, quite entire. Stem ſtriated. Root annual. Native of the South of France [l].

32. Stem erect, narrower than in *H. ſabaudum*, even. Leaves alternate, ſubſeſſile, acuminate, ſmall, naked, more finely toothed on the outſide than any of the ſorts. Peduncles at the top of the ſtalk, alternate, commonly ſimple and one-flowered, white-tomentoſe; with fewer, linear bractes. Flowers ſmall, terminating upright. Found by Kalm in Penſylvania [m].

33. Native of Spain. Introduced in 1778, by Meſſrs. Kennedy and Lee [n].

34. The ſtem has a few ſtiffiſh hairs on it, with alternate, ſhorter, ſimple branches. Leaves claſping, ovate, bluntiſh, ciliate, thinly hairy, but more underneath. Calyxes terminating, ſeveral, peduncled, ſcatteringly haired [o].—Native of Portugal. Introduced in 1783, by Mr. John Græfer [p].

This having a plumoſe, ſtipitated egret or crown to

the

the ſeed, cannot belong to this genus, and hence Gærtner has made it a ſpecies of *Helminthia*.

35. Stem firm, hirſute, three feet high. Leaves ſoft, ovate, acuminate, hairy at the edge, and on all the nerves of the lower ſurface; the lower ones are petioled, the upper ſtem-claſping, hooks blunt, teeth very ſhort, if any. Stem naked at top, many-flowered; peduncles branching, bearded with a black pile. Calyx alſo black, with hard hairs[t].

Allioni remarks, that the root-leaves indeed are toothed, but the ſtem-leaves entire, or ſcarcely tooth-letted, half ſtem-claſping, rounded at the baſe, ovate-lanceolate, duſky green above, and turning black in drying. Flowering-branches axillary. Calyx ſubcylindric, bearded with black hairs. The whole plant is hirſute, with ſhort hairs.

The ſmalneſs and great number of flowers in this plant, joined to their conical form, and the diſpoſition of the branches, which ſubdivide and divaricate at right angles, diſtinguiſh this plant from all the known Hieraciums[t].

Native of Switzerland, Dauphiné, and Piedmont. Found by Mr. James Dickſon in woods in the ſouth part of Scotland, 1789.

36. Root fibrous, perennial, yelloviſh aſh-colour on the outſide, white within. Stem upright, cylindrical, from two to three feet high or more, moſtly hairy towards the baſe, ſmooth towards the top, ſtriated, green, with red dots; branched, ſometimes from half or two thirds of the way up; the uppermoſt branches often ſpringing from one point in manner of an umbel; thoſe below alternate. Leaves alternate, at their baſe cloſely preſſed to the ſtem, and half embracing it, often crowded together in one part, ſomewhat rigid, thickiſh, ſinuate-toothletted, or very diſtinctly toothed on the edge, the teeth few, ſharp, pointing forwards, a little oblique, often ſomewhat waved, dark green, and almoſt ſmooth above, pubeſcent and paler on the under ſide, ſomewhat rugged, frequently painted with bloody ſpots; the larger ones more than five inches long, and an inch and half wide; the upper ones ſhorter and narrower, with fewer toothlets; thoſe next the flowers very ſmall, and quite entire. Branches ſubdivided, and the laſt ſubdiviſions one flowered, but not in form of an umbel, as in the next ſpecies. Peduncles erect, whitiſh with pubeſcence, a little thicker at top, having ſcales ſcattered over them, forming a thin corymb. Flowers yellow, an inch and a half in diameter. Calyx almoſt cylindric, but a little wider at the baſe; ſegments (fifty-three) lanceolate, ſharpiſh; the outer ones ſhorter, unequal, ſpreading at top, but not reflex, as in *H. umbellatum*, ſlightly pubeſcent or ſmooth, dark green; the inner equal. Florets (ſeventy-ſeven) ſtriated, ſeven or eight lines long, five-toothed, blunt, above a line wide, a little hairy on the outſide about the top of the tube. Seeds linear, ſtriated, crowned with a ſimple ſeſſile down[u]. Receptacle naked, (often a little hairy) cellular; more rugged than in the other ſpecies, according to Linneus. Dr. Withering ſays, that it is thinly ſet with fine, white, taper, chaffy briſtles. According to Villars it is alveolate, as in *Leontodon hiſpidum*. The flowers open at ſeven in the morning, and cloſe between one and two in the afternoon: in july, auguſt and ſeptember.

It varies with leaves covered with a ſhort and juſt perceptible down, ſo as to have the appearance of being ſmooth; with one flower only on a ſtem; and with broad-lanceolate leaves on very ſhort foot-ſtalks.

Native of moſt parts of Europe, in woods and hedges: in Britain not very common. It flowers from july to ſeptember.

37. Root perennial, præmorſe or truncate, yellow on the outſide, white within, having many fibres in bundles. Stem from two to four feet high, upright, ſimple, round, ſtriated, hollow, nearly ſmooth, green, frequently dotted with red, alternately eſpecially towards the top, dividing into branches. Leaves numerous, alternate, ſcattered, decreaſing in ſize upwards, ſeſſile, linear-lanceolate, having a few ſharp teeth towards the baſe, the margins and nerves ſlightly hairy, ſomewhat rugged on both ſides, four inches long, and ſeven lines broad. Flowers in a kind of umbel, ſolitary on branched, pubeſcent peduncles, which thicken under the flower, and have an awl-ſhaped bracte or two on them. Calycine leaflets unequal, linear-lanceolate, (fifty-two) dark green, ſquarroſe; outer ſomewhat downy, ſhorter, reflex at the tip; inner ſmooth. Flowers large, yellow, containing as far as ninety ſeven florets. Seeds cylindrical, ſmooth, grooved, blackiſh, crowned with a ſeſſile yelloviſh down, having ſimple rays, as long as the calyx. Receptacle naked, alveolate[x].

This ſpecies is often confounded with the preceding, by intermediate individuals that partake the characters of both, and perhaps they are more diſtinguiſhable by the eye, than by the ſpecific differences. In general this has narrower leaves, though they are not always linear, but ſometimes lanceolate, or even ovate; and the flowers grow in an umbel, or ſpring from one common centre, though the ſtem often becomes branched half way up, producing ſcattered flowers all the way; the outer calycine ſcales are more ſeparated than the inner ones, or ſquarroſe, as Linneus calls them; but this is not a conſtant character, any more than the colour of the ſeeds; ſo that there does not ſeems to be any certain mark of ſeparation between them[y]. Mr. Curtis thinks that the moſt obvious character of the ſpecies conſiſts in the narrowneſs of its leaves.

Native of moſt parts of Europe in dry paſtures. In Britain not very common. Near London, on ſandy or gravelly heaths, about Hampſtead, Barnet and Charlton; near Hilderſham and Gamlingay in Cambridgeſhire, &c. It flowers in july, auguſt and ſeptember.

It is a ſtrong-ſmelling plant, and in Scania is uſed as a dye, communicating to wool an elegant and beautiful colour[z].

This plant varies much in ſize, ſhape, ſmoothneſs, &c. of the leaves: and in the diſpoſition of the flowers. In the ſmaller ſpecimens the leaves are leſs toothed, and frequently quite entire, with the ſtalk ſometimes ſimple and one-flowered: in the larger ſpecimens the ſtalk is much branched, and the leaves are more toothed or even jagged: it rarely has the umbellate appearance in perfection[a].

38. This plant reſembles the *alpinum*; but that has oblong, blunt, ſilky leaves; weak, thin ſtems, and a lanuginoſe calyx; this has pointed leaves, villoſe but rude, of a dirty dark green, as well as the ſtem and calyx: the ſtem is more firm and thick, and frequently ſhorter; the calyx is thicker, and the flower larger.—The ſtem is from ſix to eight inches high, ſtraight, ſtout, terminated by one, two or three flowers, hirſute, with long, lanuginoſe hairs, and others that are ſmaller, placed on a black baſe, which gives a roughneſs to the ſtem. Calyx oval; ſcales lanuginoſe, ſeparate, dirty gray, a little viſcid.—Native of Switzerland, Savoy and Dauphiné.

39. See variety β. of n. 30.

40. This is allied to the preceding in its habit and leaves, to *ſpicatum* n. 35, in its flowers, and to *amplexicaule* n. 26, in its glandular hairs. Stems from a foot to two feet in height, firm, villoſe, ſtraight, with ſome axillary, ſubdivided branches. Leaves villoſe, with long hairs both ſimple and feathered; they are oblong, whitiſh, entire or ſlightly toothed, rounded at the baſe and ſtem-claſping. Flowers middle-ſized, in a gray and blackiſh calyx. Native of Dauphiné. Perennial.

41. Root oblique, truncated, perennial. Stem from a foot to two feet in height, a little inclined at the baſe, terminated by two or three ſolitary flowers. The leaves vary much; their ſhining cinereous colour and pointed extremity are their moſt conſtant characters; they have a few long hairs, eſpecially at their baſe and on their back, which are feathered; ſome of the ſame ſort are on the ſtem, and on the upper part of it ſome others which are blacker. Calyx large and aſh-coloured, with ſcales not divaricating, as in *H. villoſum*, to which otherwiſe this is very nearly allied, but lanu-

[t] Haller. [u] Villars. [x] Pollich.
[y] Pollich, Woodw. Mſs. [z] Linn. ſuec. [a] Villars. [b] Curt. lond.

ginoſe

ginofe or aſh-coloured. Seeds ſmall, black, ſhort, channelled, and crowned by a ſeſſile egret of briſtle-toothed hairs, often elbowed at the baſe, as in *H. amplexicaule*. Native of Dauphiné, and the Alps, in the beds of torrents: alſoin Auſtria, if it be Jacquin's plant.

42. This ſpecies is intermediate between *H. porrifolium* and *murorum*. Leaves middle-ſized, lanceolate, ſmooth, with black or brown ſpots, on a glaucous or aſh-coloured ground, very ſlightly toothed. Stem firm, branched, a foot or eighteen inches in height, having little, oval, acuminate, ſeſſile leaves at the diviſion of the branches. Calyx aſh-coloured. Flowers middle-ſized. Native of Dauphiné.

43. Root very thick and deep, frequently forked at the upper part, perennial. Leaves oblong, three or four inches long, and ſix or eight lines wide, glaucous, tender, bright green, with a white nerve, and a few ſinuoſities on the edge. Stem about a foot high, ſimple, or having two or three ſpreading branches about the middle, naked except a ſingle leaflet under each branch. Flowers large, pale yellow or ſulphur-coloured, as in *H. Pilofella*; turning green in drying. Native of Dauphiné, Piedmont, Switzerland.

44. Root thick, creeping, truncated, perennial. Leaves wide, cottony, aſh-coloured. Stem thin, a few inches high, terminated by two or three flowers. There is a linear leaflet under each branch, and a ſcale or two near the calyx, which is ſmooth, or very rarely a little villoſe. Seeds blackiſh; their receptacle manifeſtly villoſe. Native of Dauphiné and Italy.

H. montanum. *Scop. carn. n.* 968. *t.* 50. ſeems to bear ſome relation to this plant.

45. Root thick, truncate, perennial, covered with ruſſet membranes. Leaves wide, oblong, villoſe, with many long branched hairs. Stems ſlender, leſs villoſe, almoſt naked, half a foot high, terminating in five or ſix unequal thin long branches, each ſupporting one flower, a little larger than in H. murorum. The peduncles have two ſcales near the calyx, and one leaf at their baſe. The hairs of the calyx are in part glandular. Native of Dauphiné. Found alſo in the north of England, and commonly ſuppoſed to be a variety of H. murorum.

46. Root oblique, thick, perennial. Leaves oval, pointed, curled on the edge, which renders them concave upwards, like the bowl of a ſpoon; they have alſo ſinuations more or leſs deep at their baſe; they are entirely white with the down that covers them; this is compoſed of hairs a line in length, with little branches on them at right angles with the main hair. Stem low, divided into two or three branches, which are of the ſame length with it, and divaricate. Each is terminated by a flower, like that of *Andryala lanata*, but ſmaller. The calyx and ſtem have hairs on them of the ſame kind. The receptacle is villoſe. Native of Dauphiné.

47. This plant is cottony, like the laſt, and ſmall. It is diſtinguiſhed by its lanceolate, toothed leaves. Native of Dauphiné.

Theſe are nearly allied to Andryala lanata, which Villars makes a ſpecies of Hieracium.

48. Root thick, oblique, fibrous, truncated, perennial. Leaves like thoſe of H. murorum, not ſeſſile, however, but growing from a winged petiole, more or leſs cut; they are villoſe, but green, and pointed at the end. Stem alſo villoſe, of different heights, terminated by two or three flowers, like thoſe of *H.* murorum, but larger. Calyx villoſe, blackiſh, with a few glandular hairs. Egret ſeſſile, with ſimple hairs ſlightly toothed. Native of Dauphiné. Perhaps no more than a variety of H. murorum.

49. Root perennial. Stem ſtraight, firm, from one to two feet in height. Leaves half-ſtem-claſping, all on the ſtem, which is ſimple; they are numerous, oval or lanceolate, villoſe, pale, toothed. Stem terminated by a bunch of from ſix to twelve flowers in a blackiſh calyx, they are of a middle ſize, as in H. murorum; to which, to H. ſabaudum and ſpicatum this is ſomewhat allied. Native of Dauphiné.

50. Root perennial, oblique, thick, covered with ſcales. Root-leaves lanceolate, petioled, villoſe, dark green: ſtem-leaves two or three, ſeſſile, toothed. Stem about a foot high, terminated by ſeveral middle-ſized flowers in a calyx, which is a little viſcid. Native of Dauphiné, on walls.

It is probably only a variety of H. amplexicaule, which, as Allioni obſerves, varies remarkably in the length, breadth, thickneſs and toothing of the leaves.

51. Root perennial, long, oblique, ſimple, woody. Stem about a foot high, commonly divided into two, and ſometimes into three, elongated, unequal peduncles, almoſt naked at bottom, but a little higher, having oblong, pointed leaves, of a ruſſet colour, villoſe and toothed, or ſinuated; they are three or four inches long, and about half an inch wide, but frequently narrower, and ending in a lanceolate point: they are very cloſe, embrace half the ſtem with their rounded baſe, and ſtand out at right angles with the ſtem: of the two or three peduncles, one or two are ſtraighter, or deviate leſs from the direction of the ſtem, are more villoſe, and have from four to ſix linear ſcales; they become blacker towards the calyx: the other is oblong, black, villoſe and ſcaly, the inner ſcales a little membranous on the edge. Flowers larger, reddiſh on the outſide, pale yellow within. Seeds ſhort, brown, crowned by a ſeſſile egret of ſimple hairs, but toothed and ruſſet. The whole plant is rough, of a yellowiſh green, covered with glandular hairs, that give it a diſagreeable ſmell. Native of Dauphiné, and Savoy, on high mountains, in ſunny paſtures.

52. Root perennial, ſimple, thick, dividing at top into two parts, one of which produces a ſtem without leaves at the baſe, and the other a bundle of root-leaves without ſtem for the moſt part. Root-leaves oblong, pointed, ſinuated with ſharp teeth at the baſe, but wider, more entire, and lanceolate in the other parts. Stem-leaves claſping, with lateral earlets at the baſe, which turn back, and are often divided in two at the end. Stem a foot long, firm, thick, a little inclined at the baſe, grooved, and terminated by one, two, three, and even as far as fourteen pretty large flowers, which are all on ſeparate peduncles, from an inch to two inches in length, cloathed with ruſſet hairs, which are often glandular, like thoſe on the reſt of the plant, and darker coloured, a little dilated at the end, where they have two little ſcales. Calyx black, ſcaly, covered with glandular hairs: the ſcales are unequal, the lower two or three, the upper twelve or thirteen; they make the calyx angular, always half cloſed, and they are black and ciliate on the back. Seeds oblong, channelled, ruſſet, a little ſmaller at top; the outer ones frequently lying in the channel formed by the ſcales of the calyx. Crown ſeſſile, compoſed of ſimple hairs of a ſnowy whiteneſs, and forming a very ſoft pencil. Receptacle a little alveolate. Native of Dauphiné, in alpine meadows.

This ſort is in ſome degree allied to H. amplexicaule by its glandular hairs, and to the preceding by its deep roots; its leaves are in a juſt medium between them. It is diſtinguiſhed by its beautiful egret, and by that approaches to the genus Crepis [b].

53. Plant about a foot high, with an upright ſtem, not putting out runners. Leaves narrow, ſharp, covered with long hairs. Stem dividing in the middle. Calyx very ſmooth. Flowers ſmall, heaped on the top of the ſtem [c]. Perennial. Native of Switzerland, the Valais and Piedmont.

54. Root thick, black, perennial. Scape a hand in height, almoſt naked, ſimple, one-flowered. Calycine leaflets ovate-lanceolate, ſmooth. Native of the county of Nice, about Soſpello. It ſeems to rank between this genus and Scorzonera [d].

55. Root perennial. Leaves veined, ſomewhat like thoſe of Bupleurum; the loweſt on very long petioles, the others long-ovate, blunt, with ſcarcely any teeth, the upper ones claſping, but with ſhort and very blunt hooks, the uppermoſt linear. Stem few-flowered, brachiate. Calyx black, hairy [e]. Native of Switzerland and Piedmont.

PROPAGATION AND CULTURE.

Moſt of theſe plants are reputed to be weeds, and very few of them are cultivated, except in botanic gardens. If their ſeeds are permitted to ſcatter, they will in general propagate themſelves, and being moſtly

[b] Villars. [c] Haller. [d] Allioni. [e] Haller.

perennial, they may alſo be increaſed by parting the roots.

N. 12, and 20, Orange-flowered and Gum-Succory Hawkweed have been long known in our gardens. N. 10, 25, 26, were cultivated by Mr. Miller near ſixty years ago. A few others have been introduced ſince; as N. 19, 24, 27, 33, 34.]

They may all be propagated by ſeeds, which ſhould be ſown on an eaſt aſpected border in march; and when the plants come up, they muſt be kept clean from weeds, till they are ſtrong enough to remove, which will be by the beginning of june; then they ſhould be tranſplanted to a ſhady border of undunged ground, at ſix inches diſtance, obſerving to water them if the weather ſhould prove dry, till they have taken new root; after which, if they are kept clean from weeds, they will require no other culture: in the autumn they ſhould be tranſplanted where they are deſigned to remain; the following ſummer they will flower and produce ripe ſeeds, and the roots will continue ſome years, if they are not planted in a rich moiſt ſoil, which frequently occaſions their rotting in winter.

They may alſo be propagated by parting the roots in autumn.

Corollas four-cleft, four-ſtamened, clefts ovate, leaves obovate.

DESCRIPTIONS, &c.

1. This is a ſhrub, with an aſcending ſtem, a fathom in height, branched, looſe, ſmooth, brittle, covered with an aſh-coloured, ſhining bark. Branches ſimple, leafy, round, ſmooth, brittle. Leaves oppoſite, decuſſated, ſpreading, entire, ſcarcely nerved, veinleſs, very ſmooth, ſomewhat rigid, on round, ſmooth, petioles. Flowers terminating, ſeſſile, ſolitary, very long, white, very ſweet. Upper calyx two-leaved, ſometimes but ſeldom four-leaved; the lower has from four to ſix leaves. Tube of the corolla three or four inches long; ſegments of the border an inch in length. Anthers whitiſh. Stigmas clammy, dark green. Capſule from one to two inches long, ſlightly hexagonal, grooved. Seeds ſmall, oblong, acuminate.

Native of Jamaica, in wet coppices on the mountains, not paraſitical, but creeping among old moſſy wood; flowering in ſummer[a]. Alſo in Martinico; flowering in april[b].

2. This has a ſixth and a fifth part leſs in the fructification than in the other ſort. It is a ſhrub, native of Jamaica[c].

DESCRIPTIONS, &c.

[1. This has the flowers of Hippia, with the herb of Urtica. Native of the Eaſt-Indies[a]. Introduced in 1777, by Monſ. Thouin[b].

2. Stems procumbent, jointed, putting out rooting fibres at every joint. Leaves alternate, of the ſame form as in the third ſort: at the joints oppoſite, or frequently in threes: petioles dilated at the baſe, ſtem-claſping. Peduncles bent down, filiform, longer than the leaves. Flowers ſmall. Calyx ſimple, ſeven-leaved, with ovate-oblong ſcales. Florets of the ray fertile; of the diſk barren, few. Seeds of the ray obovate, longitudinally margined on each ſide, biſid at the tip. Receptacle naked. Found in South America by Mutis.]

3. Stem ſhrubby, eight or ten feet high, ſending out branches on every ſide the whole length. Segments of the leaves lanceolate, entire, blunt. The flowers are produced in ſmall roundiſh bunches at the ends of the branches; they are of a ſulphur colour,

[a] Swartz. [b] Jacquin. [c] Swartz.
[a] Linn. ſuppl. [b] Hort. kew.

and

and appear in may, but there is a ſucceſſion of flowers on the ſame plant great part of the ſummer.

[Scales of the calyx oblong, preſſed cloſe, membranaceous at the edge. The female corollets are continuous with the outer integument of the ſeed, exactly as in Tarchonanthus, and not ſeparate from it. Receptacle flattiſh, naked, with little depreſſed teats, having a hollowed dot in the middle, ſcattered over it. Seeds in the circumference only, elliptic, with a point at top formed by the dried corollet, narrowed towards the baſe, concavo-convex, extenuated into a ſort of wing at the ſides, pale and bald [1]. Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1731 [2].

Linneus originally made this a ſpecies of *Tanacetum*, when he publiſhed the twelfth edition of the Syſtema, (1767) the ſtructure of the fructification appeared to him to be ſo nearly allied to *Eriocephalus*, as ſcarcely to merit a ſeparate genus. In 1771, however, when the Mantiſſa was printed, he thought that it approached nearer to Iva than Tanacetum, but was diſtinct from both, and gave it the name of *Hippia*.]

PROPAGATION AND CULTURE.

3. The ſeeds rarely ripen in England; but it is eaſily propagated by cuttings, planted in a bed of loamy earth, during any of the ſummer months. Shade them from the ſun until they have taken root, and refreſh them frequently with water. Take them up with balls of earth about their roots, plant them in pots, and place them in a ſhady ſituation until they have taken new root; then remove them to a ſheltered place, among other hardy exotics, and in october put them into ſhelter. This plant, requiring only protection from froſt, muſt not be too tenderly treated.

HIPPOCASTANUM. See *Æſculus*.

HIPPOCRATEA. (*So named by Plumier in memory of Hippocrates the famous Greek Phyſician and father of Medicine.*)

Lin. gen. n. 54. *Reich.* 60. *Schreb.* 73. *Jacqu.* 9. *Juſſ.* 251.—Coa. *Plum.* 35.

Claſſ. 3. 1. Triandria Monogynia.

Nat. order of *Aceræ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five parted, very ſmall: *leaflets* roundiſh, ſpreading, incumbent, ſmaller than the corolla.

COR. *Petals* five, ovate, ſpreading, permanent, excavated at the tip, villoſe.

STAM. *Filaments* three, contiguous to the germ and ſtyle, awl-ſhaped, reflex at the tip. *Anthers* roundiſh, with a tranſverſe groove.

PIST. *Germ* roundiſh. *Style* three-ſided, awl-ſhaped, longer than the ſtamens. *Stigma* blunt.

PER. *Capſules* three, obcordate or elliptic, compreſſed, large, with two-valved cells; valves keeled and compreſſed.

SEEDS in fives or ſixes, oblong, with a membranaceous wing; at firſt ſoft, but afterwards hardening like nuts, with oblong kernels.

ESSENTIAL CHARACTER.

Cal. five-parted. *Pet.* five. *Capſ.* three, obcordate or elliptic.

SPECIES.

1. Hippocratea volubilis.

Lin. ſpec. 50. *fyſt.* 83. *Reich.* 1. 96. *hort. cliff.* 484. *Swartz obſ.* 28. *prodr.* 17.

H. ſcandens. *Jacqu. amer. t.* 9. *fict.* 10. *t.* 12.

Coa ſcandens. *Plum. gen.* 8. *ic.* 88.

[*Racemes corymbed, leaves ovate-lanceolate, ſerrate.*

2. Hippocratea comoſa.

Swartz prodr. 17.

Bejuco pendulus, flor. paniculatis. *Loeſl. itin.* 314.

Panicles comoſe, peduncles multifid, capillary, leaves ovate, acuminate, entire.

DESCRIPTIONS, &c.

1. This is a ſcandent plant (not twining, whence Linneus called it volubilis); Jacquin therefore changed the name to ſcandens.] Mr. Miller ſays it grew with him to the height of eight or ten feet, twining round ſtakes with very ſlender ſtalks.

[1] Gartner. [2] Hort. kew.

[Branches ſubdivided, bent down, with oppoſite, rigid, arched, ſpreading branchlets. Leaves petioled, oppoſite, blunt, ſtiffiſh, ſmooth. Racemes terminating, with oppoſite racemelets; flowers terminating, ſubſeſſile, crowded, greeniſh white, minute. Capſules an inch long. Seeds compreſſed, dry, in the other ſort as big as nuts [1].

Native of Carthagena in New Spain, and ſeveral of the Weſt-India iſlands.] Mr. Miller had it by Mr. Robert Millar from Campeachy. [Swartz ſays it flowers in ſpring. Jacquin ſaw it flowering both in april and december, and gathered the fruit in july. He informs us, that in the dry ſeaſon, when all the trees loſe their leaves, this plant, with the Capers and a few others, continue flouriſhing.

2. Native of Hiſpaniola.

PROPAGATION AND CULTURE.

1. It is propagated by ſeeds brought from South-America or the Weſt-Indies. Jacquin informs us that they corrupt very ſoon, and that therefore we can hardly expect to raiſe plants from ſeeds ſent to Europe. If ſo, they ſhould be ſown whilſt freſh, and ſent over in pots or tubs.] Mr. Miller, however, raiſed ſeveral plants from ſeed, which lived two years, but did not flower. He thinks that they were rotted by having too much wet, and recommends the giving them little water in winter. They are very tender, and muſt be kept conſtantly in the bark-bed in the ſtove.

HIPPOCREPIS. (ἱππου κρηπις, *Horſe-ſhoe, from the form of the legume or pod.*)

Lin. gen. n. 885. *Reich.* 958. *Schreb.* 1200. *Juſſ.* 361.—Furrum equinum. *Tournef.* 225.

Claſſ. 17. 4. Diadelphia Decandria.

Nat. order of *Leguminoſæ* or *Papilionaceæ*.

GENERIC CHARACTER.

CAL. *Umbel* ſimple. *Perianth* one-leafed, five-toothed (the upper toothlets joined, and leſs divided), permanent.

COR. Papilionaceous: *banner* heart-ſhaped, with a claw the length of the calyx: *wings* ovate-oblong, blunt: *keel* lunulate compreſſed.

STAM. *Filaments* diadelphous (ſimple and nine-cleft) aſcending. *Anthers* ſimple.

PIST. *Germ* ſlender, oblong, ending in a ſubulate, aſcending *Style*. *Stigma* very ſimple.

PER. *Legume* compreſſed and membranaceous, very long, curved inwards, one of the ſutures many times cut almoſt to the top into roundiſh ſinuſes; and hence conſiſting of ſeveral *joints*, obtuſely triangular, connected by the upper ſuture.

SEEDS ſolitary in each joint, oblong, incurved.

OBS. *The eſſential character conſiſts in the horſe-ſhoe form of the legume.*

ESSENTIAL CHARACTER.

Legume compreſſed, ſeveral times emarginate along one of the ſutures, curved.

Legumes ſtraight, ſpike oblong, terminating.

DESCRIPTIONS, *&c.*

Theſe are ſmall herbaceous plants, with unequally pinnate leaves, and ſmall ſtipules. Peduncles axillary and terminating, one or many-flowered, in umbels. Corollas, except the laſt, yellow. Claws of the petals as long as, or longer than the calyx.]

1. This is an annual plant, which ſends from the root ſeveral trailing ſtalks a foot long, that divide upwards into ſmaller branches. Leaves pinnate, compoſed of four or five pairs of narrow ſmall leaflets, terminated by an odd one, which are obtuſe, and indented at their ends; from the wings of the ſtalk come out ſingle flowers, which are yellow, and ſucceeded by ſingle pods ſitting cloſe to the ſtalks, which are about two inches long, and a third of an inch broad, bending inwards like a ſickle, and divided into many joints ſhaped like a horſe-ſhoe. This flowers in june and july, and the ſeeds ripen in the autumn, ſoon after which the plants decay.

[Native of Italy, and other parts of the South of Europe. Obſerved by Ray near Leghorn and Naples; and by Rauwolff near Tripoli.—It was cultivated here by Gerarde in 1596; and ſooner, namely in 1570, according to Lobel [a].]

2. This is alſo an annual plant, with trailing ſtalks like the preceding, to which it has great reſemblance; but the flowers of this are produced upon long, axillary peduncles. They are ſmall, yellow, and many cluſtered together. Pods narrower than thoſe of the preceding ſort, more incurved, and the outer border divided into lobes. It flowers and ripens its ſeeds about the ſame time with that.

[Native of the South of Europe. Cultivated in 1739, by Mr. Miller [b].

3. Root ſhort, woody, the thickneſs of a finger. Stems aſcending, or rather procumbent, ſhrubby and perennial at bottom. Leaves pinnate, ſmooth; leaflets about eight on each ſide, with an odd one, oblong, quite entire, blunt, with a ſcarcely conſpicuous point, ſeſſile. Peduncles round, ſlightly ſtriated, ſmooth and long, terminating in a many-flowered umbel, as in *H. comoſa*. The flowers have a ſmall degree of ſweetneſs. Calyx pale green, looſe, bilabiatae half way; upper lip ſtraight and bifid half way; lower three-toothed, the two lateral teeth aſcending, all acuminate, and almoſt of the ſame height. Corolla yellow: banner rounded, quite entire, ſtriated, aſcending at a right angle from a long channelled claw, with the edges revolute; wings obovate, very blunt, wide, almoſt the length of the banner; keel paler, ſickle-ſhaped, ſhorter than the wings, aſcending, acuminate, with a very ſlender bifid claw. Legumes oblong, blunt, ſtraightiſh or a little incurved, once, twice, or thrice ſinuated on the upper ſuture, ſmooth and brownish. Seeds ſhining, brown, cylindric, bowed, blunt [c].

Native of Minorca. It flowers in may and june, and was introduced in 1776, by Monſ. Thouin [d].

Murray obſerves, that it ſo reſembles *H. comoſa*, as to make it difficult to find any limit between them [e].

4. Root perennial, thick, woody, fibrous, yellow on the outſide, white within. The whole plant is ſmooth. Stems trailing, aſcending, grooved, from two to nine inches long, much branched. Leaves alternate, frequently coming out in bundles from the tops of the younger branches, the larger ones ſix inches long, and ſcarcely an inch broad, unequally pinnate: leaflets four or five pairs, ſometimes ſix, ſeldom more, oppoſite (ſometimes not quite ſo), ovate (according to Linneus, oval-linear) retuſe, toothed (Pollich ſays, quite entire), having a very ſhort reddiſh ſpinule at the end, bright glaucous green underneath, ſubpetioled; the largeſt are near half an inch long, and two lines wide. Stipules in pairs, awl-ſhaped, reddiſh, as it were decurrent. Peduncles axillary, round, grooved, from two to five inches long, two or three from the upper axils, and one terminating. Flowers ſix to eight or ten, diſpoſed in a circle round the top of the peduncle, after flowering bent down; pedicels ſlightly hairy, very ſhort, with a ſmall, ovate, white, bifid bractle at the baſe of each. Calyx ſmall, ſtriated, ſlightly pubeſcent; teeth ſhort, the two upper diſtant from the lower, ſpreading, leſs deeply divided. Corolla yellow: ſtandard ovate, blunt, ſmooth, reflex at the end, and along the edges, marked with brown veins, four lines long, and rather more than two lines wide, with a long gaping claw at right angles with the border; (Linneus deſcribes it as ſomewhat arched, ſtriated underneath, not bent back at the edges, only at the baſe, which being retuſe, there ſeems to be a pore as it were on each ſide:) wings ovate, blunt, a little longer than the keel, the ſame length with the ſtandard, or a little ſhorter), more than a line in width, with narrow claws cloſe to the keel, and enfolded with it: keel bluntiſh, whitening with age, arched, with a double, narrow claw. Legumes about an inch long, compreſſed, lobed on both ſides, the lower ſuture having about eight ſinuſes [f].

In German *Hufeiſenpflanze*. In Dutch, *Hoefyzer*. In Daniſh, *Heſteſkoe*. In Sweduiſh, *Hatſko*. In French, *Fer-à-cheval*. In Italian, *Ferro di cavallo*. In Spaniſh, *Hierba de la Herradura, Herradura de caballo*. In Portugueze, *Ferradurina, Eſperro cavallo*.

Native of Germany, Italy, France, Auſtria and England, in calcareous ſoils; flowering from april to july.

5. Stem ſuffruticoſe, four feet high, upright, round. Leaves ovate, quite entire, ſmooth, ternate, the middle leaflet largeſt. Flower purple, terminating in an oblong denſe ſpike. Legume peduncled, upright, flat, bearded, the outer ſuture ſeveral times and deeply emarginate. Seeds ſquare-kidney-ſhaped, ſmall, compreſſed. Native of Cochinchina [g].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which ſhould be ſown in the autumn, where the plants are deſigned to remain; and when the plants come up, they muſt be kept clean from weeds, and thinned where they are too cloſe, which is all the culture they require. The two annual ſorts will decay in the autumn after they have perfected their ſeeds, but the roots of the third will continue two or three years, provided they are not in too good ground.

[The third ſort muſt be kept in the green-houſe, and the fifth has not been introduced in Europe.

DESCRIPTIONS, *&c.*

1. The Manchineel tree is very large in the Weſt-Indies; almoſt equalling the Oak in ſize. [Jacquin ſays, it is a lofty large tree, with a very branching ſpreading head, having ſomething the air of a Pear-tree. According to Swartz, the trunk is of a middling ſize, with a gray, even, thick, milky bark, and a hard wood which is yelloviſh, with gray or blackiſh veins. Leaves rounded at the baſe, acuminate, crenate, two inches in diameter, thickiſh, dark green, ſhining, paler underneath, milky, nerved; on petioles from twelve to fifteen lines in length, margined. Flowers in aments or ſpikes. Aments cluſtered, terminating, from one to two inches in length; males ſeveral, females few, diſtinct, inſerted at the baſe, or quite diſtinct from the males, and lateral. Male flowers three or four in an ament: common perianth one-leafed, blunt; proper two-parted, turbinate, with blunt, minute teeth. Filaments one, two, three, four, connate at the baſe, longer than the calyx: anthers roundiſh, twin. Females, perianth trifid, minute, caducous; ſtyle none, ſtigmas three, two-parted, acute, reflex. Fruit a drupe, the colour, ſize and form of an Apple, ſmooth, with a ſoft ſpongy fleſh, a ſweet ſmell, and an inſipid cauſtic taſte. Within is a nut with from three to five cells, with a ſingle ſeed in each, which is three-cornered, covered with a ſhining ſilvery ſkin, and having the taſte of a hazel nut[a].] Miller ſays, the fruit is about the ſize and ſhape of a golden Pippin, and turns yellow when ripe. [It drops from the tree in great quantities, not rotting, but drying up, and does not ſeem to be eaten by any animal, except, perhaps, by a ſpecies of crab, which reſorts to theſe trees in incredible quantities, probably rather for ſhelter than for food[b]. Dr. Patrick Browne affirms, that he has known many people who have ignorantly eat of this fruit, which they had taken for crab-apples: they generally vomited in a ſhort time, and continued to complain of a burning heat in the mouth, throat and ſtomach, for many hours after. The juice of the buds of the white Cedar is eſteemed an antidote to this poiſon, and is generally uſed with ſome ſucceſs; but oily mixtures and emulſions are the moſt effectual aſſiſtants, and ſeldom fail giving relief ſoon. He adds, that he never knew any to die by this poiſon, though he has ſeen ſome who have eat nine or ten of the apples at a time.—Long ſays, that though the green fruit may be deſtructive in conſiderable quantity, yet it may be taken in ſmall quantity without danger, and is too diſagreeable, from its acrimony, to excite any deſire of eating it. When ripe, it is too inſipid to raiſe any pleaſure. He adds, that goats, ſheep and macaws feed greedily on it, in this ſtate[c].

The firſt acounts of this tree were very much exaggerated. It was ſaid to be dangerous to ſit or lie under it, and that the rain which falls from the leaves will raiſe bliſters in the ſkin. Profeſſor Jacquin informs us, that he and his companions repoſed upwards of three hours under a Manchineel tree, without receiving any injury; and that he experienced rain dropping from the leaves to be perfectly innocent. Long alſo ſays, that the Negroes do not ſuffer any inconvenience from drops of the juice accidentally falling on their ſkin, when felling this tree, or hacking off the limbs; but that if it chance to fly into their eyes, it will give them a ſevere pain for ſeveral hours[d]: and Jacquin affirms, from his own experience, that a drop of that milky juice, with which the whole tree abounds, falling on any part of the hand, except the palm, will immediately raiſe a bliſter.

The wood of this tree is frequently of a fine grain, and very beautifully clouded[e]; and, taking a fine poliſh, is much eſteemed in the Weſt-Indies for making cabinets, book-caſes, &c. It is very durable, and not ſubject to be eaten by the worm. The wood-cutters make a fire round the body of the tree before they venture to fell it, to avoid the danger of loſing their ſight by the cauſtic juice flying into their eyes. If the juice fall upon linen, it will turn it black, and on being waſhed will come into holes. If any of the ſaw-duſt happens to get into the workmen's eyes, it cauſes an inflammation; to prevent which, they generally cover their faces whilſt they are working the wood.

[The Indians are ſaid to poiſon their arrows with the juice of this tree[f]: and it exudes a gum, which has been given medicinally inſtead of Gum Guaiacum[g].

The Manchineel tree is common on the ſandy coaſts of America and the Weſt-Indies, generally growing at ſome ſmall diſtance from the ſurf. It flowers in may, and the fruit ripens in july.—Mr. Miller cultivated it here in 1739[h].

The European nations have, with little variation, adopted the Spaniſh name *Mancanilla*, which ſignifies a little apple[i].

2. This tree is from twenty to fifty feet high, with an even brownish aſh-coloured bark. Leaves on young trees frequently a foot long, but on older ones ſhorter; they are blunt, crenate-ſerrate, of a firm ſubſtance, and bright green. Spikes terminating and lateral, cluſtered, rather to be called aments. A ſingle ament

[a] Swartz obſ. [b] Jacquin. [c] Jamaica, 238.
[d] Browne. [e] Long. [f] Hort. kew.
[g] Jacquin.

of male flowers, at the beginning of the flowering-time, ſprings among other ſmall ones, flowers and falls: thick ſcales like glands cover the ament, commonly a pair oppoſite to another pair, ovate, thick, preſſed cloſe, adnate. Perianth from the ſinus of two ſcales, tubular, irregularly four-cleft, blood-red. Filaments two, connate at the baſe, reflex, longer than the calyx, blood-red: anthers twin, open at the upper edge; pollen yellow, with the atoms oblong, when viewed with a glaſs appearing to have two pellucid ſtreaks. After almoſt a month, the firſt ament falling and leaving a ſcar, the ſmaller aments of the baſe are elongated and flower, producing male flowers at top, and female flowers below. The ſcales and male flowers as in the other. The females have two ſcales to each flower, embracing the germ. Calyx trifid, two ſegments above the ſcales at the ſides, the other behind. Germ ovate, faſtened to the ament behind: ſtyle three-parted: ſtigmas thick, ſimple. Capſule oblong, ſlightly three-cornered, at length tricoccous, ſmall, three-celled, three valved. Seeds orbiculate, ſmooth, ſolitary[b].

Native of the continent of America and the Weſt-India iſlands, on mountains: flowering in march and ſeptember.

The whole tree yields a great quantity of milky juice, which becomes a reſin or gum of a thick ſticky conſiſtence, dirty colour, opaque, and of little or no ſmell: this generally ſerves for the boiling houſe lamps, in every part of the country where the tree is frequent; and is much uſed for bird-lime. The wood is ſoft and coarſe, and not much eſteemed[c]; it is uſed, however, for making hogſhead ſtaves[d].

Sapium aucuparium of Jacquin, amer. 249. t. 158. pict. t. 237., which he ſuppoſes to be the ſame as this, ſeems to be different, having longer, more acuminate, ſerrate, leaves, ſubcartilaginous-beaked at the tip, with ſubſolitary ſpikes.—H. biglandulofa of Aublet, guian. 885. is the ſame with this of Jacquin[e].]

3. This is of humbler growth, ſeldom more than twenty feet high: the leaves greatly reſemble thoſe of the common Holly, and are ſet with ſharp prickles at the end of each indenture; they are of a lucid green, and continue all the year.

Native of South America. Mr. Miller had theſe two from Dr. Houſtoun, who found this at Campeachy, and the preceding at Carthagena in New Spain.

PROPAGATION AND CULTURE.

Theſe plants are preſerved in ſome of the curious gardens in Europe, where they can never be expected to riſe to any great height, for they are too tender to live in theſe northern countries, but in ſtoves; they riſe eaſily from ſeeds, provided they are good. The ſeeds muſt be ſown upon a good hot-bed, and when the plants come up, they ſhould be each planted in a ſmall ſeparate pot filled with light ſandy earth, and plunged into a good bed of tanner's bark, treating them in the ſame way as other tender plants; but they muſt not have much wet, for theſe plants abound with an acrid milky juice, and it is certain that moſt plants which do, are ſoon killed by much moiſture: theſe plants muſt be removed into the ſtove, and plunged into the tan-bed in autumn, where they ſhould conſtantly remain, giving them very little water in winter; and in ſummer when the weather is warm, they ſhould have a good ſhare of air admitted to them, and once or twice a week refreſhed with water; by this management I have raiſed many of theſe plants to the height of five or ſix feet, which have, by their ſhining green leaves, made a pretty variety during the winter ſeaſon in the ſtove.

Leaves ovate.]

DESCRIPTIONS, &c.

1. The Sea-Buchthorn or Sallow-Thorn riſes with ſhrubby ſtalks eight or ten feet high, ſending out many irregular branches, which have a brown bark ſilvered over. Leaves narrow or linear-lanceolate, about two inches long, and a quarter of an inch broad in the middle, of a dark green on their upper ſide, but hoary on their under, with a prominent midrib; the borders are reflexed, as in the Roſemary; they are placed alternate on every ſide the branches, and ſit cloſe to them; [there are little, cluſtered, peltate, ciliate, pale ſcales ſcattered over them[a]. The branches ſpread wide, are ſtraight, ſtiff, and thorny at the ends; the leſſer ones numerous, ſcattered, ſhort and ſpreading[b]. Flowers ſolitary, appearing before the leaves, generally abortive, unleſs the ſhrub grows in its natural ſituation. Male flowers below the leaves, between a branch and a one-valved, permanent bud, the length of the flower. The female flowers are ſeſſile in the axils of the lower leaves[c]. The male flowers are ſubſeſſile, ſomewhat ſpiked, diſpoſed in four rows along the leſſer branches; the peduncles are cylindrical: bractes oblong, concave, ſpreading, as long as the calyx, reddiſh brown ſomewhat fleſhy, falling off with the flowers, ſprinkled with ſcales ſimilar to thoſe on the leaves, circular, membranous and reddiſh brown. The calyx has alſo ſcales ſprinkled over the outſide of

[a] Linn. ſpec. [b] Stokes in With. [c] Linn. ſpec.

it.

it. Filaments upright, inſerted in the bottom of the calyx: anthers two-celled, four-valved, browniſh yellow, after ſhedding their duſt ſtiff and angular; duſt or pollen nearly globular, angular, browniſh yellow, opaque, but when moiſtened with water globular and tranſparent[a].

The flowers come out from the branchlets of the former year. The berries are very abundant, on ſhort peduncles, ovate (or ovate-globular), mucronate with the ſtyle yellow when ripe[a], ſucculent, ſmooth, ſprinkled here and there with callous dots; the cell is cloathed with a very thin membrane, cohering with the ſtyle. Seed oblong, attenuated below, ſomewhat compreſſed, marked on each ſide by a depreſſed longitudinal line, very ſmooth and black[b].

The berries are gratefully acid, and are much eaten by the Tartars. They are alſo the principal food of pheaſants about mount Caucaſus[c]. The fiſhermen of the gulph of Bothnia prepare a rob from them, which imparts a grateful flavour to freſh fiſh. In ſunny ſandy ſituations this ſhrub is planted for hedges; it is uſed for dyeing yellow. Kine refuſe it, goats, ſheep and horſes eat it[b].

Native of many parts of Europe on ſandy ſea coaſts. In England, near Sandwich, Deal, Folkſtone, and the iſle of Shepey in Kent; Canvey iſland in Eſſex; Cley and Sheringham cliffs, and between Yarmouth and Winterton in Norfolk; Lincolnſhire; Whitby and Lyth in Yorkſhire.

It flowers in april and may. Ray ſays, june, and Miller, july.

It varies with red berries.] Miller ſays, that he has obſerved it only with yellow berries in England, but that he had ſeen it on the ſand-banks in Holland with red berries.

[This ſhrub is named in German *Haſtdorn*; in Dutch, *Duinbeſſen*; in Swediſh and Daniſh *Haſtorn*; in French *Argouſier*; in Spaniſh *Eſpino almarillo*; in Ruſſian *Rokitnik*.

2. This has the appearance of the former ſort; but the leaves are broader, only half the length, of an ovate or oblong-ovate form; on the upper ſurface they are green, with diverging hairs, in bundles, ſcarcely to be diſcerned by the naked eye: on the lower they are ſilvery with hairs and ſcales, and have ruſt-coloured dots ſcattered over them. The branches are oppoſite; and the racemes ſimple among the firſt leaves, upright, and ſhorter by half than the leaves.—Native of Canada[d].]

PROPAGATION AND CULTURE.

Theſe ſhrubs may eaſily be propagated by ſuckers from the root, taken off in autumn, and tranſplanted into a nurſery. After one year's growth, they will be fit to tranſplant where they are to remain. They may alſo be increaſed by layers, but the roots ſpread, and put up ſuch abundance of ſuckers, that there is no neceſſity to be at this trouble. There being little beauty in theſe ſhrubs, it will be ſufficient to have one or two of them in plantations.

Scape naked, root tuberous.

DESCRIPTION, &c.

1. Root perennial, creeping, white, jointed; the joints furniſhed with numerous capillary fibres. Stems numerous, a foot and half or more in height, upright, quite ſimple, ſmooth, ſtriated, round, jointed, ſpongy; the pith like a thread in the centre, compact, and in the roots tough. Leaves in whorls at each joint, from eight to twelve or thirteen in number, linear, ſeſſile, perfectly ſmooth and entire, acuminate, without veins, appearing hollow-dotted when magnified; thoſe under water reflex. Flowers axillary ſeſſile, one to each leaf, in the whorls that are above water. Filament ſeated on the top of the germ, at firſt very ſhort, but on ſhedding its pollen becoming as long as the piſtil: anther two-lobed, purpliſh and rather large. Style very ſhort, naked: ſtigma tapering to a point, white and downy when magnified. Seed oblong, hard, white within, and in the centre brown, covered with a thin membrane or aril[a]. Gærtner calls it a nut, of an elliptic-globular form, on a very ſhort peduncle, ſmooth and bay-coloured: the ſhell thick, hard, white, one-celled, valveleſs: the ſeed of the ſame ſize and ſhape with the ſhell, ſoft and whitiſh.

Linneus remarks, that the flower of this plant is as ſimple as can be conceived, having neither calyx nor corolla, only a ſingle ſtamen and piſtil, and one ſeed. The ſituation alſo of the leaves, in whorls, is not uſual in European plants, except in the natural order of Stellatæ[b].

The flowers in the beginning of ſummer are moſtly hermaphrodite, but at the cloſe of it many of them are female[c].

Whilſt ſeveral botaniſts are diſcarding the claſs Gynandria from the ſyſtem, Retzius is deſirous of having this plant removed from the claſs Monandria into it, on account of the ſtamen being placed upon the germ[d].

Native of many parts of Europe, in ponds, ditches, marſhes and rivers, eſpecially where there is a depth of mud, and the froſt cannot reach the roots. In quiet waters it grows upright, in large lakes to the height of ſeveral feet; in running waters it bends with the ſtream. In ſome countries it is a troubleſome weed in rivers, and choaks up the ditches; but by abſorbing a great quantity of inflammable air it is reputed to aſſiſt in purifying the putrid air of marſhes. Gmelin ſays, that the wild-ducks in the north feed upon it.

[a] Curtis, Relh. Linn. [b] Linn. [c] Curtis and Scop. [d] Obſ. 3. p. 7. and 6. p. 18.

Goats

Goats alſo are ſaid to eat it. We do not know that it is of any other uſe. In England it is not very common; it is found however in ſeveral places in Cambridgeſhire, Oxfordſhire, Weſtmoreland, Staffordſhire, Leiceſterſhire, &c. Near London it is more rare; Blackſtone found it in Harefield river and Uxbridge moor, Hudſon in the New River near Hornſey, and Dr. Milne near Stoke Newington and Highgate. It flowers from may to auguſt. Others give april to june for the time of flowering. I never found it ſooner than may.

Gerarde calls this plant *Female Horſe-tail*, and Parkinſon *Marſh barren Horſe-tail*; Mr. Hudſon firſt named it *Mare's-tail*. In French it is *Peſſe d'eau*, which is a tranſlation of one of its old names *Limnopeuce*, lake or water Pine. In German it is *Schafthalm*, *Tannenweed*, &c. In Dutch, *Katteſtaart*, *Paardeſtaart*. In Daniſh *Heſterumpe*, *Vand-ſtudeknæa*. In Swediſh, *Haſtvans*. In Italian, *Hippuride*.

2. This is always very diſtinct from the preceding by its only having four leaves to a whorl, and their being ſpatulate-ovate and blunt [1]. According to Retzius they are lanceolate, and the upper leaves are in fives. It has the appearance of Elatine Alſinaſtrum, and is clearly a gynandrous plant [2].

It is a native of Sweden, and was firſt diſcovered by Schulſen near Aboa in Finland.

3. This is a ſtemleſs plant, with a fibrous creeping root, having many, roundiſh, ſcattered, ſmall, black, hairy tubers, which are eatable. Leaves awl-ſhaped, long, erect, cluſtered. Scape four feet high, very ſtraight and ſimple, round, ſtriated; within tubular, divided by many tranſverſe membranes. Spike terminating, contracted, long, upright, netted-ſculy. Stamen and ſtyle long, equal. Stigmas two, oblong. Seed orbiculate, naked, protected by a ſcale of the ſpike.—Native of marſhes in Cochinchina [3].

DESCRIPTION, *&c.*

This is a ſmall tree, ſeldom exceeding fifteen feet in height, and dividing into round, long, ſmooth, bending and reclining branches, by which it ſupports itſelf on neighbouring ſhrubs. Bark aſh-coloured. Leaves oblong, a little broader at top, blunt at both ends, quite entire, ſmooth underneath, having ſoft, decumbent, ſcarcely conſpicuous hairs on the upper ſurface, and being from three to ſix inches long; the petiole has two upright briſtly ſtipules at the baſe. Common pedunceles thick, very ſhort and numerous beautifully ſurrounded, entire and very long branches, and by means of twelve ſemioval ſhort bractes, finiſh in a quadrilocular top; the partial pedunceles being one-flowered, an inch long, ſolitary, and therefore four to each common peduncle. Flowers beautiful, but without ſcent, yellow, an inch in diameter.

Native of Carthagena in New Spain, in woods; flowering in june, and ripening the ſeeds in ſeptember [4].

HIRCULUS. See *Saxifraga*.

HIRTELLA. (*Dimin. from* hirtus; *ſo named from the hairineſs of the branches.*)

Leaves elliptic ſhining with hairy ſubcoriaceous racemes upright, flowers five-ſtamened.

DESCRIPTIONS, *&c.*

1. This is a tree, with a trunk from twenty-five to thirty feet in height, and a ferruginous bark. Branches wand-like, ſcattered, ſpreading, ſubdivided, round, hirſute: branchlets round, hirſute. Leaves on ſhort petioles, alternate, ſmooth, entire, acuminate, from three to ſix inches long. Stipules in pairs, lanceolate, at the baſe of the petioles, deciduous. Racemes axillary, hirſute, ferruginous. Flowers alternate, pedunculed, ſomewhat rough with hairs. Petals rounded, with claws, emarginate, blueiſh. Filaments five, all fertile, placed on one ſide, long, whitiſh, blue: anthers roundiſh. Germ roundiſh, villoſe: ſtyle lateral: ſtigma blunt. Berry obovate, compreſſed, hairy-rough, dry. Native of Cayenne, where it is called by the French Bois de Gaulette [5]. Introduced in 1782, by Mr. Alexander Anderſon [6].

2. This is a branching tree, twenty feet high, frequently leſs. Leaves quite entire, ſhining, on ſhort petioles, alternate, five inches long. Racemes terminating, villoſe, half a foot in length. The flowers have no ſcent; the ſtamens and ſtyle are placed croſswiſe. The calycine ſegments are ovate-roundiſh, concave, equal, reflex. Petals ſpreading, equal, deciduous, white. Filaments three, filiform, flatted at the baſe, upright, very long, permanent, finally rolled in ſpirally: anthers roundiſh. Germ, roundiſh villoſe,

[1] Linn. ſuppl. [2] Obſ. 3. p. 7. [3] Lourdo. [4] Jacquin. [5] Swartz. [6] Hort. kew.

compreſſed on the ſide, without any ſtamen cloſe to it: ſtyle filiform, hirſute at bottom, almoſt the length of the ſtamens: ſtigma ſimple *.—Native of the Weſt Indies, Martinico, Jamaica, Domingo: flowering in april and may.

3. Branches round, with a purpliſh bark, rough-haired at top. Leaves on very ſhort petioles, alternate, ſpreading, abundant, an inch and half long, quite entire with a ſmall point, veined, hairy along the veins, of a different colour underneath. Stipules awl-ſhaped, very rough haired. Racemes axillary, from upright ſpreading, ſolitary, longer than the leaf, extremely hirſute. Pedicels copious, alternate, ſolitary or ſometimes but ſeldom two together. Bractes ovate, frequently two on the pedicel, hirſute on the outſide, and others lanceolate, at the baſe of the pedicel. Calyx hirſute on the outſide, coloured, tomentoſe within, ſomewhat ſilky. Filaments five, long. Style hirſute at the baſe.—Native of Cayenne, where it was found by Rohr *.]

HIRUNDINARIA. See *Aſclepias* and *Lyſimachia Nummularia*.

HOEING is beneficial to plants: 1ſt, for deſtroying weeds; 2dly, becauſe it diſpoſes the ground better to imbibe the night dews, keeps it in a conſtant freſhneſs, and adds a vigour to the plants and trees, whoſe fruit by that means, becomes better conditioned than otherwiſe it would be.

This operation is performed by the hand, with an inſtrument called a Hoe, which is well known to every gardener. There are ſeveral ſizes of theſe; the ſmalleſt, which is called an Onion Hoe, is not more than three inches broad, and is uſed for hoeing Onions; not only to cut up the young weeds, but alſo to thin the Onions, by cutting up all thoſe which are too cloſe. The next ſize is near four inches and a half broad, and is called a Carrot Hoe; this is uſed for hoeing Carrots or any other crop which requires the ſame room as thoſe. The largeſt ſize is about ſeven inches broad, and is frequently called a Turnep Hoe, being uſed for hoeing Turneps; but this is generally uſed by the kitchen-gardeners, for hoeing between all their crops which are planted out, or ſtand ſo far aſunder as to admit an inſtrument of this breadth to paſs between the plants. Beſides theſe ſorts of Hoes, which are contrived to draw towards the perſon who uſes them, there is another of a different form, which is called a Dutch Hoe; this is made for the perſon who uſes it to puſh from him, ſo that he does not tread over the ground which is hoed. This is a very proper inſtrument for ſcuffling over the ground to deſtroy weeds, in ſuch places where the plants will admit of its being uſed, and a perſon will go over a much greater ſpace of ground in the ſame time with one of theſe inſtruments, than with the common Hoe; but this inſtrument is not ſo proper for hoeing our crops, ſo as to leave the plants at a proper diſtance, nor will it penetrate the ground ſo far; therefore the other ſort of hoe is to be preferred to this, becauſe it ſtirs the ground and looſens the ſurface, whereby the dews penetrate the ground, and thereby promote the growth of the plants. Of late years there has alſo been another inſtrument introduced in the field culture, called the Horſe Hoe, which is a ſort of plough with the ſhare ſet more inclining to a horizontal poſition than the common plough.

The utility of the Horſe-hoeing huſbandry, is firſt, in proportioning the number of plants which the ground is ſuppoſed capable of nouriſhing properly. The ſecond is, by frequent ſtirring the ſurface of the land, all weeds which rob the crop of its nouriſhment are deſtroyed, and the clods of earth are hereby divided and pulverized, ſo that the roots of the plants can more eaſily penetrate them, and ſearch their proper food; beſides the dews and moiſture are eaſily imbibed in the looſe ground, whereby the plants receive a greater ſhare of nouriſhment.

There are few perſons who properly conſider of what conſequence the ſtirring and breaking the ſurface of the ground is to all crops growing therein. I have frequently made trial of this, when the crop has been ſo bad as to be thought not worth ſtanding, which has been occaſioned by the great quantity of rain which has fallen, whereby the ſurface of the ground has been ſo cloſely bound, as that the plants could find no nouriſhment, but have changed their uſual verdure to a purple colour, and have made no progreſs; but upon hoeing the ground and breaking the clods, the plants have put out new roots, and have flouriſhed exceedingly. From many repeated trials of this kind I can affirm, that if the Wheat in general was ſowed in rows, ſo as that the plough may be brought between them in the ſpring, to looſen the ground, which by the winter's rains may have been too cloſely bound, the crop would more than double what is the common produce. And by this method of huſbandry I can affirm, that all crops will be ſo much improved, as to doubly anſwer the difference of expence, and leſs than a fifth part of the ſeed will be enough for the ſame ſpace of ground. The common ſwing plough will anſwer all intents of Horſe-hoeing.

HOGWEED. See *Boerhavia*, *Heracleum*, *Polygonum aviculare*.]

HOLCUS (*of Pliny: from* ολκος, *tractus, a furrow, &c.*)

Lin. gen. n. 1146. *Reich.* 1252. *Schreb.* 1565. *Mieg. act. helv.* 8. t. 4. *Gærtn. t.* 80. *Juſſ.* 30.

Sorgum. *Mich.*

Claſſ. 23. 1. Polygamia Monoecia.

Nat. order of *Gramina* or *Graſſes*. *Graminæ*, Juſſ.

GENERIC CHARACTER.

* *Hermaphrodite* flowers, ſeſſile.

CAL. *Glume* one-flowered, two-valved, ſubovate, obtuſe, coriaceous, awnleſs: *outer valve* large, concave, ſlightly three-toothed at the tip, embracing the *inner valve*, which is oblong, rolled up on the ſides.

COR. *Glume* two-valved, tender, villoſe, leſs than the calyx: *outer valve* ſmalleſt, placed within the inner calycine valve, in moſt of the ſpecies bifid at the tip, and awned: *awn* from the cleft of the glume, long or ſhort, jointed, twiſted; ſometimes none.

Nectary three-leaved; two of the leaflets cartilaginous, truncate; the third oppoſite, ovate or lanceolate, villoſe.

STAM. *Filaments* three, capillary, very tender. *Anthers* oblong, bifid.

PIST. *Germ* ovate. *Styles* two, capillary, diverging. *Stigmas* oblong, feathered.

PER. none; but the glumes of the corolla and calyx are rolled about the ſeed and encloſe it.

SEED ſolitary, ovate, covered, armed with the awn of the corolla, which however eaſily falls off.

* Jacquin. * Vahl.

* *Mole*

* *Male* flowers peduncled, solitary or in pairs accompanying the hermaphrodite, smaller.

CAL. *Glume* two-valved: *valves* ovate-lanceolate, sharpish, chaffy, awnless; the *outer valve* concave, embracing the inner, which is narrower.

COR. *Glume* two-valved, smaller, more tender: *outer valve* within the inner valve of the calyx, shorter, two-toothed, awnless; the *inner valve* doubled upon the edges.—*Nectary* as in the Hermaphrodites.

STAM. *Filaments* three, as in the Hermaphrodite.

PIST. *Germ* small, angular, abortive. *Styles* two-bristle-shaped. *Stigmas* none.

ESSENTIAL CHARACTER.

HERM. *Cal.* Glume one or two-flowered. *Cor.* Glume awned. *Stam.* three. *Styles* two. *Seed* one.

MALE. *Cal.* Glume two-valved. *Cor.* none. *Stam.* three.

SPECIES.

Spikes digitate, glumes with the outer valve pricked with a hole in the middle.

DESCRIPTION, &c.

1. Culm two feet high, thickneſs of a ſwan's quill, covered with the ſheaths of leaves; both of them are hiſpid. Leaves uſually ten in number, a finger's breadth, hiſpid. Spike very thick with very ſhort pedicels, having at the top a bundle of briſtles, within which are two ſeſſile flowers. Calyx two-valved, membranaceous, two-flowered. Outer petal of the hermaphrodite flower mucronate; of the male blunt-

blunt. Style longer than the flowers, woolly, slightly bifid at top. Anthers oblong. This is an annual Grass, and a native of the East Indies [a]. Cultivated by Compton Bishop of London, at Fulham [b].

2. This is an annual Grass bearing a great resemblance to the next species, but very distinct from it by the black calyxes and the seeds of a snowy whiteness [c].

Though Linneus has made this a distinct species, it is more probable that Gærtner is right in making it only a variety of Holcus Sorghum, from which it differs in nothing more than in having the calyx when ripe cartilaginous, black and shining.—It was observed in Persia by Lerche [d].

3. Panicle contracted, ovate, upright, but as it ripens drooping. Calyx green, pubescent. Awn brown at bottom, smooth and whitish at top [e]. Seed naked, free, subglobular, compressed a little on both sides, smooth without shining, of a milky whiteness with a black umbilical dot. There are several varieties of Sorghum, of the most cultivated plants. The most remarkable, besides H. bicolor, is the red-seeded one, cultivated among the Caffres. Of this the calyx when ripe, is cartilaginous, pale chestnut-coloured, very smooth, shining only half the length of the seed; which is naked, obovate-globular, much acuminate towards the base, red, not shining [f].

Miller describes the Sorghum and saccharatus together, and indeed they differ so little as scarcely to merit being considered as distinct species. According to him] the stalks of these plants rise five or six feet high, are strong, reedy, and like those of the Maiz, or Turkey Wheat, but smaller. The leaves are long and broad, having a deep furrow through the centre, where the midrib is depressed on the upper surface, and is very prominent below. The leaves are two feet and a half long, and two inches broad in the middle, embracing the stalks with their base. The flowers come out in large panicles at the top of the stalks, resembling, at first appearance, the male spikes of the Turkey Wheat; these are succeeded by large roundish seeds, which are wrapped round with the chaff.

They are both natives of India, where this grain is much used to feed poultry, and is frequently sent to Europe for the same purpose. [This is much cultivated in Arabia, and most parts of Asia Minor. It has been introduced into Italy, Spain, Switzerland, and some parts of Germany; also into China, Cochinchina, and the West Indies, where it grows commonly five or six feet high, or more, and being esteemed a hearty food for labourers, is called Negroe Guinea Corn. Its long awns or bristles defend it from the birds [g]. In England, the autumns are seldom dry and warm enough to ripen the seed well in the field.

In Arabia it is called *Dora* or *Durra*; the flower is very white, and they make good bread of it, or rather cakes, about two inches in thickness [h]. The bread which they make of it in some parts of Italy is dark and coarse. In Tuscany it is used chiefly for feeding poultry and pigeons; sometimes for swine, kine and horses. Cæsalpinus says, that cattle fed on the green herb are apt to swell and die, but thrive on it when dried. They make brushes of it in Italy, which Ray observed in the shops at Venice [i]. It was cultivated here in 1596, in John Gerarde's garden [k].

In German this is named *Mohrhirse, Sorgsamen, Sorgsaat, Welsche Hirse, Indianische Hirse.* In Dutch, *Gewoon Zorghzaad, Negerkoorn.* In French *Houque sorgo, Grand Millet.* In Italian, *Saggina, Saggineila, Sorgo, Melica.* In Spanish, *Alcandia, Melca.* In Portugueze, *Milho Sorgo.* In Tartarian, *Myssur, Suburge.* In Japonese, *Siokn, Kiki.* In Guinea, *Guiarnatt.*

4. Culm smooth and even. Panicle spreading, purple, awns white at the tip. To each female (or hermaphrodite) flower there are two male flowers, which are pedicelled [l].

[a] Linn. spec. [b] Ray hist. [c] Linn. mant. [d] Ibid. [e] Gærtner. [f] Browne. [g] Rauw. Ray hist. Groo. orient. [h] Ray hist. [i] Hort. kew. [k] Linn. spec.

The root is perennial and increases by lateral runners like the reed. Leaves a foot and half in length, a finger or an inch in breadth, somewhat glaucous, with a remarkable white line running along the middle, as in Tragopogon. Culms from three feet to near five feet in height, reedy, jointed, with leaves on them like the lower ones, only smaller. Panicle erect, from a hand to a long span in length, brownish. Seeds oblong, mucronate, somewhat turgid, brown, shining.

Native of Syria. Cultivated at Oxford in 1699 by Jacob Bobart, from seed sent over to Huntington [l]. Scheuchzer had his specimens from Triumfetti and Jussieu, and gives a very long description. Scopoli refers to Scheuchzer's name, and describes it as an Andropogon. Allioni adopts Scopoli's name, and says that it is wild near Turin, and in other parts of Piedmont and Montferrat.

5. Culm round, upright, with bearded joints. Leaves narrow, striated, shorter than the sheath; the last spathaceous, of the same height with the culm; sheath bearded at the mouth. Panicle upright. Peduncles in a sort of whorl, capillary, bearded at the base, quite simple, three-flowered, sometimes proliferous; pedicels usually in pairs, seldom solitary. Middle flower hermaphrodite, sessile; lateral male, pedicelled; all ovate-lanceolate, somewhat compressed, bearded at the base with fulvous hairs. Glumes of the hermaphrodite flower brown, with fulvous hairs scattered over them, especially at the edge and tip, smoother in the middle, shining: of the males villose, narrower, sharper, not shining.—It is a native of the East Indies, and has the habit of the preceding, but is smaller in all its parts [m].

6. Root biennial. Plant the height of a man (with a solid, jointed, upright and very simple culm, *Lour.*) from the lower joints of which issue rooting fibres. Leaves like those of the Sugar-cane, with a white longitudinal line [n], stiffly lanceolate, smooth, large, with clasping petioles. Panicle large diffused. Calyx coloured, almost closed, longer than the seed, hairy at the base and tip. Awn of the corolla twice as long as the calyx, strait, not withered or jointed. Seed lenticular, thick, black, shining [o]. The male flowers scarcely open.

According to Gærtner, the panicle is oblong and loose, with the racemelets when ripe spreading horizontally. Flowers almost obovate, obscurely angular. Calyx one-flowered, with the valves when ripe coriaceous, very smooth and shining, straw-coloured or ferruginous, closely surrounding the seed. Corolla membranaceous, very thin, villose at the edges, with a short bristle-shaped, bent-jointed dorsal awn. Seed elliptical, covered with the permanent calyx and corolla, convex on one side, flattish on the other.

The villosity of the calyx is as inconstant as the colour, and is almost always lost in maturity: the colour generally changes to dark or black: these circumstances therefore are unfit to use for specific differences. This species and H. sorghum differ little in habit or any thing else, except the one having a naked the other an incrusted seed.

It differs from H. Sorghum in having the panicle upright, in a sort of whorl; racemes spreading very much, horizontal, subpendulous, not a small ovate panicle: general rachis of the panicle smooth, not rugged: glumes villose on every side, not at the tip only: one glume of the corolla has a long writhed awn in all the florets, not in the terminating florets only.

Native of the East Indies [p]. Cultivated in China and Cochinchina [q]. Browne calls it Guinea Wheat, and says it had been lately introduced into Jamaica. Mr. Miller cultivated it here in 1759 [r].

7. Creeping Soft grass resembles the next species, says Linneus, but the calyxes are more acute than in the other species, and rather acuminate.—According to Schreber, the roots are creeping, like Triticum repens, (Quich or Couch grass); the culms are taller; the leaves green; the calyx smooth; the awns straight, after flowering jointed, projecting somewhat beyond

[l] Hist. oxon. [m] Vahl. [n] Linn. spec. [o] Loureiro. [p] Linn. spec. [q] Loureiro. [r] Hort. kew.

the

the calyx. Mr. Curtis says it is usually a smaller plant than Meadow Soft-grass, or if it be as tall, it has a much more scanty panicle. The spikelets have not that brilliant colour which marks those of *lanatus* at their first appearance. The joints are woolly, and the spikelets large and pointed, with the awn much longer than the calyx. Both flowers are hermaphrodite, contrary to Linneus's specific character, and both apparently produce fertile seeds. This grass also rarely occurs but in and about woods and in hedges; whereas the lanatus is a very general grass in meadows. Ray affirms that it is very common in corn fields; but Mr. Curtis says that he has seldom seen it in that situation. It flowers in july, and is a worse grass than the *lanatus* on account of its creeping roots.

Haller makes it an *Avena*, to which genus, in the opinion of Dr. Stokes, its structure shows it really to belong. Schreber, in his spicilegium, makes it an *Aira*, to which Mr. Curtis also would refer it.

8. Root perennial, but not creeping. Stems from two to three feet high, upright, round, pubescent, with three or four joints. Leaves a quarter of an inch in breadth, grayish from being covered with soft hairs; the sheath marked on the outside with purple lines, and shining within; the ligule or membrane blunt or truncate, hairy on the outside and about the edge. Panicle at first contracted, reddish, and drooping a little; but afterwards upright, spreading and whitish. The velvet-like softness of the whole plant, and the redness of the opening panicle, render this grass very conspicuous. It abounds in meadows, is frequent by road sides, and sometimes grows on walls. It flowers in june and july. Haller speaks highly of this grass as food for cattle, but it is not at all esteemed among us. The seed however, being easily collected, is sometimes sent to London in great quantities, as pure grass-seed.

Lightfoot says that the stalks are used for making ropes for fishing boats in the isle of Skye; but there are better grasses for this purpose [a].

A gentleman's horses having been much disordered with a malady, which occasioned an extraordinary discharge of urine, the hay on which they fed being examined, was found to contain scarcely any other grass but this; and on changing the hay the distemper ceased [b].

This fact ought to be well ascertained, before the *Holcus lanatus* is recommended, with Dr. Anderson [c], as one of the most valuable kinds of meadow-grasses; though since he calls it creeping soft-grass, and talks of its running roots, he may mean H. mollis, which is one of the vilest weeds, at least in arable lands.

Mr. Marshall, in his Rural Economy of Yorkshire, says that it is far from an eligible grass for cultivation, is now entirely exploded by judicious husbandmen, and has been supplanted by Rye-grass (Ray-grass): the growers of the seeds being the only persons who have profited by its cultivation, eighty bushels having been produced from an acre [d]. It goes there under the name of *White Hay-seeds*.

In his minutes of the midland counties he says it ranks high as a pasture plant, for cattle at least; that a piece which abounds in it to one half is esteemed excellent for cheese; is favourable to the growing of young heifers, and the fatting of Scotch bullocks, and that cattle of every kind do well in it, but not horses [e].

9. This has the habit of Aira cærulea. Culms two feet high, narrow, somewhat nodding. Leaves several, smooth and even, rugged about the edge, hairy at the mouth of the sheath. Panicle filiform, very little branched, somewhat nodding, weak. Peduncles usually two-flowered. Male flower ovate, thick.—Native of Virginia and Canada [f].

10. Leaves flat, long, with thickish, striated sheaths. Panicle attenuated, with very short, clustered, branching peduncles. Glumes oblong, striated, acuminate. Calyx one-leafed, very small.—Native of Virginia, in marshes [g].

11. Root perennial, creeping, covered at top with sheaths of leaves in clusters. Culms decumbent at bottom, branched, covered with the sheaths of leaves below, naked above, a foot high, even, quite simple, almost leafless. Leaves with swelling sheaths, stiff, more serrate than in the others. Raceme compound, narrow. Flowers villose, awnless, purple. Calyx two-flowered, soft, villose, covering the florets. Male flower three-stamened: female ovate, with cartilaginous petals.—Found at the Cape of Good Hope by Thunberg [h]: who has also discovered several other species, not here enumerated.

12. Roots perennial, jointed, creeping. Culm three-feet high, with few joints. Leaves narrow, very long, overtopping the panicle, convoluted so as to resemble the stalk of a rush, stiff, stout, and pungent. Panicle small, slightly scattered [i]. The two lateral flowers are male and three-stamened; the third in the middle is hermaphrodite and two-stamened.

Native of wet pastures in the colder parts of Europe, Canada, and Siberia. Introduced here in 1777, by Brook Watson, Esq.

This grass has a sweet smell, and is collected into bundles, to lay among cloaths and linen, and is hung over beds in some countries with a view to procure sleep [k].

13. Culm upright, a foot high, smooth, sheathed. Leaves the length of the culm, involuted, awl-shaped, striated. Panicle patulous, with filiform pedicels. Calyx lanceolate, longer than the florets, dirty yellow, shining; one glume larger and longer than the other. Florets three; two lateral, sessile, male, larger, outer valves pubescent, especially towards the edge, shining-brown, awned a little below the tip, obliquely truncated, awns the length of the valve; middle floret smaller, awnless, lanceolate. Stamens three, fertile in the males, barren in the middle flower. In appearance quite similar to the preceding, but differing in its involuted leaves, and florets of double the size.—Native of Terra del Fuego. *Fabricius* [l]: and of New Zealand, if it be the same plant. *Forster*.

14. Culm even, scarcely a foot high. Leaves very broad, with broadish striated sheaths. Branches of the panicle simple, wand-like. Flowers alternate, solitary, on capillary pedicels, ovate-oblong. Calyx shorter. The first flower unarmed; the second and third armed with recurved spines at the upper edge.—Found in China by Osbeck [m].

15. Culm jointed, even, ascending, branched, about a foot high. Leaves alternate, remote, narrower. Spikes five, linear, equal, somewhat hairy, upright, pedicelled: rachis filiform, hairy, with two-flowered teeth; the lower floret sessile, the upper on a hairy pedicel the length of the lower floret, which is hermaphrodite; the upper is male. The former has oblong, convoluted petals, of which the outer is punched with a round hole in the middle; the awn is terminating, long, twisted. The latter is smaller, with linear convoluted petals, the outer not punched, and no awns.—Native of the East Indies [n].

Guinea Grass.

Guinea Grass, so called from its having been originally introduced into the West Indies from the coast of Africa, is a species of Holcus, according to Browne [o]. The characters of it, he says, agree pretty well with those of *Panicum*, in general, but the flowers commonly grow very luxuriant, and though often hermaphrodite, are generally observed to be male and female distinct, surrounded by separate involucres, and standing on distinct pedicels within the same calyx.

The blades of this grass, when flourishing, appear not unlike those of Wheat, only rather broader and longer; and the stalks, during the first growth, are also much like those of Wheat, but they get weaker and less, the oftener the grass is fed upon or cut, till at last it becomes a fine, rich and entire swath.

Guinea-grass appears capable of thriving in any situation, in respect to climate and soil, and can bear the effects of dry or wet weather in a most remarkable manner.

[o] Jamaica. p. 366. species 2.

In wet weather it may be cut once in a fortnight, and ſometimes oftener, when the land is new or fertile. In dry weather, it is long before it withers, and when reduced to ſuch a ſtate as to ſeem totally deſtroyed, will revive with a ſlight ſhower in a few hours: when rain falls, though ſo ſparingly as to be of little or no ſervice to common paſtures, it will occaſion this to be fit for uſe in a few weeks; nay in ſome ſituations, not too much expoſed to the ſun, it will flouriſh from occaſional dews only. When ready to feed, it is from ſix to eight feet high, but it is generally fed or cut when only three or four.

It agrees with all kinds of ſtock; and horſes, mules and kine will fatten ſo faſt upon it, that the two former will be in a good condition in a couple of months, or leſs: and the latter will become fit for the butcher in the courſe of three months[1].

Guinea-graſs is ſaid to have been brought from Africa to America by the Engliſh at the beginning of the preſent century; and the French have introduced it thence into St. Domingo, &c. about the year 1768. It has made its way in the Continent of North America from Carolina to New England: and attempts have been made to introduce it into Europe. It ſeems too tender to be of any advantage as fodder in England. In Jamaica it is now generally cultivated to ſupply both their ſtabled and working cattle: and Sir Archibald Campbell, who was governor of that iſland, carried the ſeed to the Eaſt Indies, where it was propagated with ſucceſs, and was of great ſervice to the cavalry; the horſes having before that been fed on the roots of graſs[2].]

PROPAGATION AND CULTURE.

3, 6, &c. Theſe plants are propagated in a few gardens for the ſake of variety, but as they are late in ripening their grain here, ſo they are not worth cultivating for uſe. The ſeeds ſhould be ſown on a warm border, or upon a gentle hot-bed in march; and when the plants come up, they ſhould be thinned and planted at the diſtance of a foot aſunder in the rows, and the rows ſhould be three feet diſtance; the culture after this, is to keep the ground clean from weeds, and draw the earth up with a hoe to the ſtems of the plants; if the ſeaſon proves warm, their panicles will appear in july, and the grain will ripen in ſeptember, but in bad ſeaſons their grain will not ripen here.

[If the ſeeds however were procured from Germany or Switzerland, climates not very different from our own, it ſeems not improbable but that Sorghum might be made to grow to advantage on ſome of the warmer ſoils of our iſland.

7, 8, &c, For the culture of theſe ſee GRASS

Guinea Graſs.

The manner of cultivating this Graſs in the Weſt Indies is to make the land intended for it perfectly bare by hoeing, and then to dig holes from three to five feet diſtance, according to the quality of the ſoil. The holes ſhould be large, and deep enough to bury a few roots of the graſs a good depth. The roots are taken from a neighbouring field or nurſery, and the graſs being topped within three or four inches they are put into the holes, well covered with earth, and preſſed down by the foot. Care is taken to keep the plants free from weeds by repeated hoeings. The beſt months for planting are april and may, for the graſs will then ſeed in ſeptember and october, at which time it ſeeds moſt abundantly. The ground muſt be quite clean when the ſeed is ready to drop; and if the ſpaces between the roots are then ſtirred with the hoe, it will be found very beneficial.

When the ſeed is all fallen, ſtock are turned in to tread it into the ground, and feed upon the graſs. On very rich and new land, the graſs at firſt will grow ſo rank as to produce very thick ſtalks, which, by running up the noſes of the ſtock, will prevent them from eating it ſo cloſe as they otherwiſe would. When however it is eaten as near the ground as poſſible, the remaining graſs, with the roots which were planted, are dug out with the hoe and burnt off. After this, the graſs, if favourable rains come, will grow from the ſeed, and by covering the ground in may following, will be perfectly eſtabliſhed for ſeveral years, according to the quality of the land, to be cut for hay, or to ſtand for paſture.

Whenever the graſs grows thin, holes may be opened in ſuch places, and roots again planted to ſupply it, and by this attention, a field will ſcarcely ever be ſo totally worn out as to require the labour of being at any one time replanted.

With very little care in its infancy, this graſs will overcome all other graſs and weeds; and in ground full of ſtones and rocks, though planted at great diſtances at random, as the ſoil admits, it will ſpread itſelf about them in a few months, and at laſt cover them entirely.

If the ſtalks of Guinea-graſs be buried a few inches deep, each joint of it will take root, and grow luxuriantly: or it may be propagated directly from ſowing the ſeed, the ground being previouſly prepared for that purpoſe; but the ſeed will lie many months in the ground before it makes its appearance. Some planters do not ſtock up the roots which are planted, when the graſs has ſeeded; and others depend upon what they afford, by continually feeding or cutting the graſs when at a certain height, without ever allowing it to ſeed[3].]

DESCRIPTIONS, *&c.*

1. Stems decumbent, creeping, ſomewhat rigid at bottom. Leaves oppoſite, orbiculate-cordate, ſubſeſſile. Stipules four on each ſide, membranaceous. Pedunclelateral, elongated, aſcending, ſeven-flowered, one in the middle, and three on each ſide, from a peduncle farther branched. Pedicels when mature viſcid, dropping with the fruit. Calycine leaflets oblong, acute, concave. Petals white, upright, lanceolate, ſhorter than the calyx. Styles divaricating [a].

Native of Jamaica and Surinam. In the former it is common, and thrives very luxuriantly. Browne calls it the larger American Chickweed: and ſays, that it grows in tufts, and ſeldom riſes above ten or twelve inches from the ground; that the ſmaller birds feed much upon the ſeeds, but that it is ſeldom put to any other uſe, except that large wads of the freſh plant heated over a gentle fire are ſometimes applied to hard and painful ſwellings, in order to relax the parts and diſpoſe the obſtructions to a reſolution.

2. This plant is very ſmall, ſeldom riſing above ſix or ſeven inches from the ground. Calycine leaflets and petals five, as in the other, but only two ſtamens, and theſe placed in the ſame line with the petals.—Native of Jamaica, but not common [b]. Annual

3. Petals white, ſubtrifid, ſmaller that the calyx [c].—Native of New York.

4. Native of Malabar.

5. Root annual, ſlender, a little branched, fibrous, running perpendicularly down. Stems numerous, filiform, jointed, round, perfoliate, upright, from two or three to ſix inches high, having moſtly three joints; the ſpace betwixt the two loweſt is ſmooth; the others for the moſt part viſcous and hairy. Leaves in pairs at each joint, very entire, erect, cohering at the baſe, each pair croſſing that above and below, ſmooth on the under ſide, the upper ſurface and margins a little hairy, concave at the baſe, keel-ſhaped, ovate, obtuſe and fleſhy. Root-leaves narrower and longer than the others. Two external bractes large, and of the ſame form with the leaves; the internal lanceolate and very ſmall. Pedunclesnumerous, all from one centre, terminating, unequal, ſome hanging down, ſome declining a little, ſome erect, and ſome bent in different directions, filiform, one-flowered, permanent [d]. Calyx never opening, marked at the baſe with black dots. Petals white, but often tinged with purple on the outſide, converging, concealed within the calyx. ſo that the tips only peep out [e]; they are marked with five white ribs, and are toothed at top, but the number of teeth vary from two to five; as do alſo the ſtamina and piſtils, the former from three to five and even ten, the lattter uſually three, but ſometimes four or five [f]. Capſule ovate, ſmooth, ſhining, one-celled, ſix-valved, ſuperior, ſcarcely opening beyond the middle: receptacle columnar, free, hiſpid with the umbilical chords, little more than half the capſule in length. Seeds numerous (about ſeventy), ſubovate, compreſſedly three-cornered, rugged with ſcattered dots, with a groove on the back, and a ridge on the belly, rufeſcent [g].

Native of Spain, Italy, France, Germany, Switzerland and England; where it was firſt noticed on walls at Norwich, and on walls and banks in the neighbourhood, by Mr. John Pitchford in ſpring 1765 [h]. It was alſo found near Bury in Suffolk by Sir Thomas Gery Cullum, Bart. It is an annual plant, flowering in april and may.

Hudſon and Withering place it among the Ceraſtiums; whilſt Swartz would remove the Alſine media or common Chickweed to this genus of Holoſteum.

Villars makes two ſpecies of the umbellatum.—1. Smooth, with triandrous flowers. 2. Hairy, with decandrous flowers. The firſt ſmooth, ſmaller and greener. The ſecond, very villoſe, larger, aſh-coloured green all over, the peduncles and calyxes not clammy, as in the other. This is not ſo common as the other.

DESCRIPTION, *&c.*

This is a tree, with alternate, petioled, ſimple, oblong, lanceolate-ovate, ſubſerrate, ſhining, nerveleſs, ſweet leaves. The peduncles burſt forth from buds upon the topmoſt branchlets, eight or ten together, before the leaves, and are diſpoſed in a very ſhort ſpike, on very ſhort, one-flowered pedicels, cloathed with ſmall, concave, villoſe leaflets. The flowers are ſucceeded by ſubſeſſile fruits, below the leaves, in a very ſhort ſpike. It flowers early in the ſpring, and is then extremely ſweet. The juice or a decoction of the leaves will dye linen and ſilk of a bright yellow colour.—Native of Carolina*.

HORDEUM. *Either* horridum *from* horreo, *on account of its long awns or beards; or ſince it was anciently writ* Fordeum, *rather from* φορεω *to feed or nouriſh, whence* φορδη *and* Forbea, *and changing the* b *into* d, Fordeum. *Voſſius.*)
Lin. gen. n. 98. *Reich.* 104. *Schreb.* 129. *Gærtn. t.* 81. *Tournef.* 295. *Juſſ.* 32.
Claſſ. 3. 2. Triandria Digynia.
Nat. order of *Graſſes*, or *Gramina. Gramineæ*, Juſſ.

GENERIC CHARACTER.

CAL. Common *Receptacle* lengthened in a ſpike. *Glume* ſix-leaved three-flowered: *flowers* ſeſſile: *leaflets* diſtant, in pairs, linear acuminate.
COR. two-valved; *lower valve* bellying, angular, ovate-acuminate, longer than the calyx, ending in a long *awn*: *inner valve* lanceolate, flat, ſmaller. *Nectary* two-valved; *leaflets* ovate, ſharp, ciliate.
STAM. *Filaments* three, capillary, ſhorter than the corolla. *Anthers* oblong.
PIST. *Germ* ovate-turbinate. *Styles* two, villoſe, reflex. *Stigma* ſimilar.
PER. none: the corolla grows round the ſeed, without opening.
SEED oblong, bellying, angular, acuminate to both ends, marked with a groove on one ſide, (covered with the permanent corolla; radicle of the embryo ſix, *G.*)
OBS. *In ſome ſpecies all the three flowers contained in an involucre are hermaphrodite and fertile; in others the ſide flowers are males, and the middle one only is a fertile hermaphrodite.*

ESSENTIAL CHARACTER.

Cal. lateral, two-valved, (valves narrow, acuminate, diſtant, all together forming a ſix-leaved involucre), one-flowered, by threes, at each toothlet of the rachis.

Awns and involucres briſtle-ſhaped and very long.]

DESCRIPTIONS, &c.

1. The firſt ſort is the common Spring Barley, which is principally cultivated in England; of this the farmers make two ſorts, viz. the common and rath-ripe Barley, which are the ſame: for the rath-ripe has only been an alteration, occaſioned by being long cultivated upon warm gravelly lands. The ſeeds of this, when ſown in cold or ſtrong land, will the firſt year ripen near a fortnight earlier than the ſeeds taken from ſtrong land; therefore the farmers in the vales, generally purchaſe their ſeed Barley from the warm land; for if ſaved in the vales two or three years, it will become full as late in ripening as the common Barley of their own product; and the farmers on the warm land are alſo obliged to procure their ſeed Barley from the ſtrong land, otherwiſe their grain would degenerate in bulk and fulneſs, which by thus changing is prevented. This ſort of Barley is eaſily diſtinguiſhed by the two orders of beards, or awns, which ſtand erect; the chaff being alſo thinner than that of the ſecond and fourth ſorts, it is eſteemed better for malting.

2. The ſecond ſort is rarely cultivated in the ſouthern parts of England, but in the northern counties, and in Scotland, is generally ſown, being much hardier than the other ſpecies, ſo will bear the cold; this has its grains diſpoſed in ſix rows: the grain is large and plump, but it is not ſo good for malting, which is the reaſon for its not being cultivated in the ſouthern parts of England, where the other ſorts, which are much better for that purpoſe, thrive well.

3. The third ſort is the long-eared Barley, which is cultivated in many parts of England, and is an exceeding good ſort; but ſome farmers object to it becauſe they ſay the ears being long and heavy, it is more apt to lodge; this has the grains regularly ranged in a double row, lying over each other like tiles on a houſe, or the ſcales of fiſhes. The huſk, or chaff of this Barley is alſo very thin, and it is much eſteemed for malting.

4. The fourth ſort is uſually called Sprat Barley; this has ſhorter and broader ears than either of the other ſorts; the awns, or beards, are longer, and the grains are placed cloſer together, and the awns being long, the birds cannot ſo eaſily get out the grains; this ſeldom grows ſo tall as the other ſpecies, and the ſtraw being ſhorter and coarſer, is not very good fodder for cattle.

[1. In Spring Barley the lower flowers are apt to be imperfect. The ſpike is as it were diſtich, though there are ſeveral rows. In all the flowers the two glumes or chaffs of the calyx are ſhorter than the flower, awl-ſhaped, and end in a ſhort awn or beard. The outer corolline chaff is much hollowed, with the ſides folded in, the back ciliated, and the tip continued into an awn three inches in length: the inner chaff is awnleſs[a].

It is not known where this or any other ſort of grain grows wild. Cardan pretended that Barley was a native of Athol in Scotland! Reideſel ſays the ſame of Sicily: and it has lately been affirmed to be found on the banks of Samara, a river of Tartary. Diodorus Siculus aſcribes the firſt culture of Barley to Oſiris, who diſcovered it in a wild ſtate. The ancients fed their horſes with barley, as we do with oats. It was eaten alſo in bread by the lower ſort of people; and the Gladiators were called *Hordearii*, from their feeding on this grain[b]. In ſome of the ſouthern parts of Europe they have two crops of Barley; one ſown in autumn and cut in may, and another ſown in ſpring and cut in autumn. In ſome of the northern parts of Europe it is called *Korn* excluſively; and it is much cultivated there on account of its taking a leſs time to ripen than other ſorts of grain. In Lapland fifty-eight days only, or about two months, elapſe, between the ſowing and the cutting it. But it is the ſecond ſort which is uſually ſown in northern climates. Rath-ripe or Patney Barley is ſaid to have been returned to the barn in England in two months.

β. Siberian Barley, called in German *Himmelſgerſte* or *Himmelſkorn*; in Daniſh, *Himmelſbyg* or *Thorebyg*; in Swediſh, *Himmelſborn*; in French, *Orge celeſte*, was introduced in 1768 by Mr. Haliday, who received a wine-glaſs full of this grain on the 25th of may 1767, from a member of the ſociety of Arts, &c. at London, with this information, that a foreign nobleman had preſented that ſociety with about a pint of it, and that it came from Siberia. In 1768, Mr. Haliday, having near a quart of the ſeed, ſowed the whole in drills, the firſt week in may. The produce was hung up in ſacks in the ear, and in the beginning of april 1769 was threſhed out, and produced near a buſhel. On the 19th and 20th of that month it was ſown in drills, and was reaped on the 14th and 15th of auguſt. The produce was about thirty-ſix buſhels of clean corn.

Two buſhels, weighing 132 pounds, being ſent to the mill, yielding 80 pounds of fine flour, equal to London ſeconds, 40 pounds of a coarſer ſort, and 12 pounds of bran ſuperior to wheat bran. The beſt flour made excellent bread, ſufficiently light, and ſo retentive of moiſture, as to be as good twelve or fourteen days after baking, as wheaten bread on the fourth day. And 12 pounds of barley, and the ſame quantity of wheat flour, equally fine, being made into bread, and baked in the ſame oven, the wheaten loaf weighed 15, and the barley 18 pounds. Two buſhels of it being malted, were brewed into a half barrel of ale and another of ſmall beer, both of which proved very good[c].

Siberian Barley has a broader blade of a much deeper green than common Barley, at firſt coming up, the ears are ſhorter, having only from five to nine grains in length, whereas thoſe of the common ſort have from nine to thirteen; and in all ſtages it is a fortnight forwarder than common Barley. The two ſorts being ſown in the ſame field on the 28th of april 1774, three buſhels of each, the common Barley produced thirty-ſix buſhels and a half weighing 52 pounds each, and the Siberian produced thirty-two buſhels weighing 58 pounds each: but the ſoil was very dry, and much inclined to a gravel, which was much to the diſadvantage of the latter, for it requires a richer land[d].

2. Winter or Square Barley, commonly called Bear Barley, Bere or Big, having ſix rows of grain, has a much thicker ſpike than common or ſpring Barley; but it is alſo much ſhorter: the number of grains

[a] Haller. [b] Plin. 18. c. 7. [c] Hunter's Eſſays, p. 133. [d] Bath papers. 1. 108.

however in an ear or ſpike is greater, in the proportion of at leaſt three to two. I have frequently counted forty-two grains, when common Barley had only twenty-two. The ear is ſeldom more than two inches in length; it is ſquare, with two rows of grains on two of the ſides; on the other two a ſingle row of grains runs up the middle, ſo that the former rows are awned only laterally, and the latter on the ſides and along the middle alſo. The lower flowers are imperfect in both. The outer valve of the corolla has a rough awn or beard from four to ſix inches in length.

This ſpecies is ſeldom cultivated in the ſouthern parts of England, the grain, though large and plump not being eſteemed ſo good for malting as common Barley: but in the northern counties and in Scotland it is generally ſown, becauſe it will bear the cold much better. In ſome of the more ſouthern parts of Europe it is ſown in autumn.

3. Common or Long-eared Barley differs eſſentially from the two others. The ſpike or ear is very long, flatted, or tranſverſely greater in breadth than thickneſs, with a double row of defective or male, and conſequently barren florets on each flat ſide, and a ſingle row of fertile florets at each edge. The valves of the calyx, outer glume, huſk or chaff are linear, and ſhorter by half than the corolla or inner chaff, which ends in an awn or beard which is ſtraight and ſixteen times its own length, when ripe it is coriaceous, angular, and continues cloſe about the grain; when this is taken off the grain appears of an ovate form, grooved and angular [e].

β. Mortimer ſays that they cultivated in Staffordſhire *Tritico-Speltum*, a ſort of naked Barley or Wheat-Barley, the ear ſhaped like Barley, but the grain like Wheat; that it is much ſown at Rowley, Hamſtal, and Redmore, where they call it French Barley; that it makes good bread, and good malt, and yields a good increaſe [f]. No mention being made of this grain in Mr. Pitt's View of the Agriculture of this County, drawn up for the conſideration of the Board of Agriculture, and printed in 1796; we may conclude that it is no longer cultivated there.

Villars deſcribes it as having a larger, finer grain, the weight and ſize of Wheat, and ſeparating from the huſk, whence its name; he adds that it is nicer reſpecting ſoil, and more difficult to cultivate, but yields a larger produce, and is of a better quality than common Barley.

4. Sprat or Battledore Barley, differs from the common ſort in being of a lower ſtature, and in having a ſhorter, broader ear, with cloſer grain, ſtanding out more from the rachis, and having ſhorter awns. Between the two rows of fertile flowers, are two other rows of male or barren flowers, as in the preceding ſpecies, but more conſpicuous [g].

Barley in Greek Κριθη; in Latin *Hordeum*; in German is *Geyſte*; in Dutch, *Gerſt*; in Daniſh, *Byg*; in Swediſh, *Bingg* or *Korn*; in French, *Orge*; in Italian, *Orzo*; in Spaniſh, *Cebada*; in Portugueze, *Cevada* or *Sevada*; in Ruſſian, *Jeſchmen* or *Jeſmin*.

5. Bulbous Barley-graſs is ſo named from its bulbous roots, wrapped up in whitiſh or browniſh, broad, membranaceous, fibrous coats, and having ſtrong fibres hanging from them. Culms two or three, from a foot or eighteen inches to three and even four feet high in different ſituations, with four or five joints; the ſheaths of the lower leaves hirſute with ſhort cloſe hairs; of the upper ſmooth and ſtriated, ending in a thin, white, ſubdiaphanous membrane (or ligule) about half a line in length. Leaves a ſpan or a foot, ſometimes only a hand long, a line and a half or two lines wide, rough and finely toothletted at the edge, having very ſhort hairs on both ſurfaces, but not ſo many on the lower. Spike narrow, three or four, ſometimes near ſix inches long, and three or four lines broad. The two lateral florets in each ſet are on a pedicel half a line in length, and are themſelves near half an inch long, with awns near an inch in length, flatted at bottom: the middle floret is ſeſſile, about five lines in length, with the outer glume ending in an awn uſually more than an inch long, and at the baſe two other awns eight or ten lines long [h].

Native of Italy and the Levant. Scheuchzer found it about Rome in may. Introduced here in 1770, by Monſ. Richard [i].

6. Common Wall Barley-graſs, Way-Barley, Way-Bennet, or rather Way-Bent; called alſo Wild Rie or Rie-graſs, has an annual root; numerous ſtems a foot or eighteen inches in height, round, ſmooth, frequently branching at bottom, where they are procumbent, and bend at the joints; theſe are about five in number, ſwell out, and are either paler than the reſt of the culm or tinged with purple; the upper part of them is erect. Leaves from three or four to ſix inches in length, and a quarter of an inch in breadth, covered with a ſoft down on both ſides. Spikes from two to three inches long, pale green: the middle floret of each ſet is fertile and ſeſſile; the lateral ones are male and on very ſhort pedicels; all three are alike in ſize and ſhape, or ſometimes the latter are a little ſmaller. The outer valve of the corolla ends in an awn an inch or an inch and half in length, and rough when handled from the point downwards; the inner valve is truncate at the end, and ſlightly emarginate, from the baſe ſprings a ſtraight awn, the length of the filaments.

This is a very common graſs by the ſide of paths and under walls, whence its trivial names both in Latin and Engliſh. It flowers during the greater part of the ſummer. In the iſle of Thanet it is ſaid to be well known to the innkeepers by the name of Squirrel-tail graſs. They find that if horſes feed on it ſome time, the beards ſtick into their gums, and make them ſo ſore, that they are in danger of being ſtarved. The gentleman who related this fact, added, that on the road he had a bill put into his hand, ſignifying, that at ſuch an inn travellers might depend on having hay without any mixture of Squirrel-tail graſs [k].

Wall Barley-graſs never being found in the body of a meadow, it may be doubted whether it is not rather the next ſpecies which produced this bad effect, and if ſo that muſt not be recommended for culture. But it is now aſcertained to be the 8th ſpecies.

It is an old notion that this Graſs is Barley degenerated, though it bears more reſemblance to Rie. Haller ſeriouſly combats this error, but it is ſurely now too vulgar a one to be neceſſary to contradict it.

Wall Barley-graſs in German is *Mauſegerſte*, *Gerſtengras*, *&c.* In Dutch, *Muurgerſt*, *Baſtardgerſt*, *Muizenkorn*. In Daniſh, *Byggræs*, *Fandens-ax*. In Swediſh, *Villkorn*. In French, *Orge des murs*.

7. Meadow Barley-graſs, from its reſemblance to Rie named by Johnſon Rie-graſs, was ſuppoſed by Linneus to be nothing more than a variety of the preceding. Ray obſerved long ſince, that it differs in being much taller, and having ſhorter ſpikes and awns. Its height is almoſt double that of the other. The ſpike is more green, only half the length of that, ſquare, with the awns of the calyx as long as thoſe of the corolla. The anthers alſo are three times as long as in H. murinum, and yellow, whereas in that they are blueiſh, and almoſt ſquare. None of the involucres are ciliate. The middle floret is ſmooth; the two lateral ones, though they have a piſtil as well as ſtamens, yet being very minute, they never come to maturity. Our Engliſh authors mark it as perennial; Monſ. Villars takes it to be annual.

Native of Sweden, Denmark, France, Switzerland, England, and probably moſt parts of Europe, in good meadows, of which it ſometimes forms a conſiderable portion.]

Mr. Miller affirms that this is a very good graſs for paſtures, and has perennial roots, with leafy ſtalks that do not become ſtiff and harſh: and that, if duly rolled, the roots will mat and form a very cloſe ſward. [It is however a late graſs, and is thought not to be ſo productive as ſome others. For *Ray-graſs*, which is ſometimes, but erroneouſly, called Rie-graſs, and is very different from this, ſee *Lolium perenne*.

[e] Gaertner. [f] Huſbandry, p. 102. edit. 2. [g] Ray hiſt. and Bauh. hiſt. [h] Scheuchzer. [i] Hort. kew. [k] Curtis.

8. At firſt ſight this reſembles the common Wall-Barley-graſs, inſomuch that it might be doubted, until experiments are made by culture, whether it be a diſtinct ſpecies; becauſe ſalt water and ſea air make graſſes put on a different appearance. It differs however in having ſhorter pyramidal ſpikes, made up of a greater number of florets, more crowded together, with the awns more ſtanding out, thoſe at botom longeſt, and becoming gradually ſhorter towards the top of the ſpike [1]. The involucres are roughiſh, neither ciliate nor ſcored. Florets ſmooth, the middle one in each ſet ſeſſile, the lateral ones on very ſhort pedicels at the baſe of their involucre, and their awns ſomewhat longer than the floret [2].

Native of Barbary and the ſouthern parts of Europe, and of England, in ſalt marſhes near the ſea; flowering in june and july.

This is marked as annual both by Engliſh and foreign botaniſts, and is deſcribed by Allioni under the name of *Hordeum geniculatum*. He ſays it differs evidently from the next ſpecies, and that in cultivation it acquires a loftier culm, with a ſpike twice or thrice as long as in the wild plant, but that the character of the incurved culm continues.

9. This has the habit of H. murinum, but the involucres and briſtle-ſhaped awns are four times the length of the whole ſpike, which gives this graſs a ſingular appearance [3].—The ſtem-leaves are four or five inches long, and a line or a line and a half wide, villoſe with ſhort hairs above, below eſpecially towards the top rough, if drawn downwards through the fingers. Awn four, five, or near ſix inches in length [4].

Linneus, in the ſpecies plantarum, aſſigns Canada for the native place of this graſs, and Kalm for the diſcoverer. In the 13th and 14th editions of the ſyſtema vegetabilium it is ſaid to be a native of Smyrna: and Scheuchzer ſays that it was ſent from Smyrna by Sherard. In the catalogue of the royal garden at Kew it is aſſigned to Canada and Hudſon's Bay; and is ſaid to have been introduced in 1782, by the Hudſon's Bay Company. In the latter work it is marked as biennial. It is ſurely improbable that of graſſes ſo nearly allied as theſe ſome ſhould be annual, others biennial, others perennial. Schreber refers this ſpecies to Elymus, as Hordeum ſylvaticum is by moſt botaniſts, and alſo Triticum caninum.]

PROPAGATION AND CULTURE.

Barley.

1—4. All the ſorts of Barley are ſown in the ſpring of the year, in a dry time; in ſome very dry light land, Barley is ſown early in march; but, in ſtrong clayey ſoils, it is not ſown till april, and ſometimes not until the beginning of may; but when it is ſown late, if the ſeaſon does not prove very favourable, it is late in autumn before it is fit to mow, unleſs it be the rath-ripe ſort, which is often ripe in nine weeks from the time of ſowing.

Some ſow Barley upon land where Wheat grew the former year; but when this is practiſed, the ground ſhould be ploughed the beginning of october in a dry time, laying it in ſmall ridges, that the froſt may mellow it the better, and this will improve the land greatly; and if this can be ploughed again in january, or the beginning of february, it will break and prepare the ground better; then in march the ground is ploughed again, and laid even where it is not very wet; but in ſtrong wet lands the ground ſhould be laid round, and the furrows made deep to receive the wet. When this is finiſhed, the common method is to ſow the Barley-ſeed with a broad caſt at two ſowings; the firſt being harrowed in once, the ſecond is harrowed until the ſeed is buried; the common allowance of ſeed is four buſhels to an acre. This is the quantity of grain uſually ſown by the farmers; but if they could be prevailed on to alter this practice, they would ſoon find their account in it; for if leſs than half that quantity is ſown, there will be a much greater produce, and the corn be leſs liable to lodge, as I have many years experienced; for when corn or any other vegetable ſtands very cloſe, the ſtalks being drawn up weak, are incapable to reſiſt the force of winds, or bear up under heavy rains; but when they are at a proper diſtance, their ſtalks will be more than twice the ſize of the other, and are ſeldom laid. I have frequently obſerved in fields where there has been a foot-path through the middle, that the corn which has ſtood thin on each ſide the path has ſtood upright, when all the reſt on both ſides has been laid flat on the ground: and whoever will obſerve theſe roots of corn near the paths, will find them tiller out (i. e. have a greater number of ſtalks) to more than four times the quantity of the other parts of the field. I have ſeen experiments made by ſowing Barley in rows acroſs divers parts of the ſame field, and the grains ſowed thin in the rows, ſo that the roots were three or four inches aſunder in rows, and the rows at a foot diſtance; the intermediate ſpaces of the ſame field were at the ſame time ſown broad caſt in the uſual way; the ſucceſs was this, the roots which ſtood thin in the rows tillered out from ten or twelve, to upward of thirty ſtalks on each root, the ſtalks were ſtronger, the ears longer, and the grains larger than any of thoſe ſown in the common way; and when thoſe parts of the field where the corn was ſown in the uſual way have been lodged, theſe parts ſown thin have ſupported their upright poſition againſt wind and rain, though the rows have been made not only lengthways, but croſs the lands, in ſeveral poſitions, ſo that there could be no alteration in regard to the goodneſs of the land, or the ſituation of the corn; therefore where ſuch experiments have been frequently made, and always attended with equal ſucceſs, there can be no room to doubt which of the two methods is more eligible; ſince if the crops were only ſuppoſed to be equal in both, the ſaving more than half the corn ſown is a very great advantage, and deſerves a national conſideration, as ſuch a ſaving, in ſcarce times, might be a very great benefit to the public. I know the farmers in general are very apt to complain if their corn does not come up ſo thick as to cover the ground green in a ſhort time, like Graſs fields: but I have often obſerved, that when from the badneſs of the ſeaſon it has come up thin, or by accident has been in part killed, their corn has been ſtronger, the ears longer, and the grain plumper, ſo that the produce has been much greater than in thoſe years when it has come up thick; for the natural growth of corn is to ſend out many ſtalks from a root, and not riſe ſo much in height; therefore it is entirely owing to the roots ſtanding too near each other, when the ſtalks are drawn up tall and weak. I have had eighty-ſix ſtalks upon one root of Barley, which were ſtrong, produced longer ears, and the grain was better filled than any which I ever ſaw grow in the common method of huſbandry, and the land upon which this grew was not very rich: but I have frequently obſerved on the ſides of hot-beds in the kitchen-gardens, where Barley-ſtraw has been uſed for covering the beds, that ſome of the grains left in the ears having dropped out and grown, the roots have produced from thirty to ſixty ſtalks each, and thoſe three or four times larger than the ſtalks ever arrive at in the common way: but to this I know it will be objected, that although upon rich land in a garden, theſe roots of corn may probably have ſo many ſtalks, yet in poor land they will not have ſuch produce; therefore unleſs there is a greater quantity of ſeeds ſown, their crop will not be worth ſtanding, which is one of the greateſt fallacies that can be imagined; for to ſuppoſe that poor land can nouriſh more than twice the number of roots in the ſame ſpace as rich land, is ſuch an abſurdity, as one could hardly ſuppoſe any perſon of common underſtanding guilty of; and yet ſo it is, for the general practice is to allow a greater quantity of ſeed for poor land, than for richer ground; not conſidering that where the roots ſtand ſo cloſe, they will deprive each other of the nouriſhment, and ſtarve themſelves, which is always the caſe where the roots ſtand cloſe; and this a perſon may at firſt ſight obſerve, in any part of the fields where the corn happens to ſcatter when they are ſowing it; or in places where, by harrowing, the ſeed is drawn in heaps, thoſe patches will

[1] Ray. [2] Withering. [3] Linn. ſpec. [4] Scheuchzer.

will ſtarve, and never grow to a third part of the ſize as the other parts of the ſame field; and yet common as this is, it is little noticed by farmers; otherwiſe they ſurely would not continue their old cuſtom of ſowing. I have made many experiments for ſeveral years in the pooreſt land, and have always found that all crops which are ſown or planted at a greater diſtance than uſual, have ſucceeded beſt; and I am convinced, if the farmers could be prevailed on to quit their prejudices, and make trial of this method of ſowing their corn thin, they would ſoon ſee the advantage of this huſbandry.

When the Barley is ſown, the ground ſhould be rolled after the firſt ſhower of rain, to break the clods and lay the earth ſmooth, which will render it better to mow, and alſo cauſe the earth to lie cloſer to the roots of the corn, which will be of great ſervice to it in dry weather.

Where Barley is ſown upon new broken up land, the uſual method is, to plough up the land in march, and let it lie fallow until june, at which time it is ploughed again, and ſown with Turneps, which are eaten by ſheep in winter, by whoſe dung the land is greatly improved; and then in march following the ground is ploughed up again, and ſown with Barley as before.

There are many people who ſow Clover with their Barley, and ſome have ſown Lucerne with Barley; but this method is not to be commended, for where there is a good crop of Barley, the Clover or Lucerne muſt be ſo weak as not to pay for ſtanding; ſo that the better way is to ſow the Barley alone without any other crop among it, and then the land will be at liberty for any other crop, when the Barley is taken off the ground; but this practice of ſowing Clover, Rye-graſs, and other Graſs-ſeeds, with corn, has been ſo long and univerſally eſtabliſhed among farmers, that there is little hope of prevailing with thoſe people to alter a cuſtom which has been handed down to them from their predeceſſors, although there ſhould be many examples produced, to ſhew the abſurdity of this practice.

When the Barley has been up three week or a month, it will be a very good method to roll it over with a weighty roller, which will preſs the earth cloſe to the roots of the corn, and thereby prevent the ſun and air from penetrating the ground, which will be of ſingular ſervice in dry ſeaſons; and this rolling of it before it ſtalks, will cauſe it to till out into a greater number of ſtalks; ſo that if the plants ſhould be thin, this will cauſe them to ſpread ſo as to fill the ground, and likewiſe ſtrengthen the ſtalks.

The time for cutting Barley is, when the red colour of the ears is off, and the ſtraw turns yellow, and the ears begin to hang down: in the north of England they always reap their Barley, and make it up in ſheaves, as practiſed here for Wheat, by which method they do not loſe near ſo much corn, and it is alſo more handy to ſtack; but this method cannot ſo well be practiſed where there are many weeds amongſt the corn, which is too frequently the caſe in the rich lands near London, eſpecially in moiſt ſeaſons; therefore when this is the caſe, the Barley muſt lie on the ſwarth till all the weeds are dead; but as it is apt to ſprout in wet weather, it muſt be ſhaken up, and turned every fair day after rain to prevent it. When it is carried in, it ſhould be thoroughly dry, otherwiſe if it be ſtacked wet, it will turn muſty; or if too green, it is ſubject to burn in the mow. The common produce of Barley, is two and a half, or three quarters on an acre, but I have ſometimes known ſix or ſeven quarters on an acre.

[*Time of ſowing Barley.*

The farmer is governed by ſeaſons, and by other neceſſary work which he may have to perform; but when he can, to ſow early is one of the moſt important articles in the culture of Barley. If three ploughings can be given in time, it is beſt to get the ſeed in ſome time in march at fartheſt; and ſome farmers, rather than defer the ſowing, will throw in the crop on one earth[s]. In Norfolk they commonly ſow on their light lands in april, and on the moiſt lands in may; and they think that where they are much ſubject to weeds, they have the beſt crops when they ſow late. Early ſowing, however, has been gaining ground for ſome years paſt. And it appears from an experiment accurately made by a very intelligent coltivator, that more grain was produced from ſowing in january than at any other time. The land was a deep ſand, valued at ſix or ſeven ſhillings the acre; it had been under clover, and was folded the ſame as for wheat, in november. Two buſhels of Barley were ſown on the 16th of november, 1785, and harrowed in, upon one earth only; and the ſame quantity was ſown the middle of every month till may 1786 incluſive. The firſt ſown came up a week ſooner than the wheat ſown on the ſame day by the ſide of it, and was very flouriſhing till the firſt ſharp froſt ſet in, which damaged the blade, but did not ſeem to affect the root. The other ſowings had two earths; one caſt, or half the ſeed, was ploughed in, and the other half harrowed in. The ſecond ſharp froſt killed ſome of the ſecond ſowing, and a good deal of the firſt; but both, together with that ſown in january, ſeemed to ſuffer ſtill more, by the ſharp cutting winds in the month of march, when there was no ſnow to cover the blade. Theſe three ſowings, particularly the firſt, had their plants very much thinned by the froſts and winds; but the roots that were left ſtubbed very much in the ſpring, and had very long ears, with from thirty to thirty-ſix grains in each. The ſowings in february and march loſt few if any of their plants, and were both forward enough to be harveſted on the ſame day with the three preceding ſowings. That ſown in april was full a fortnight later, and the laſt ſown in may was entirely deſtroyed by rooks, there being no other ſown ſo late in the neighbourhood. It would have been the ſame with the early ſowings, had not the evil been guarded againſt. However advantageous therefore early ſowing may be, yet neither this nor any other laudable practice will be of any avail in open fields, where lands are intermixed, unleſs where there is a general conſent; and if one farmer only were to ſow early, he muſt have as many keepers as he has pieces of land, and thus have a better crop than his neighbours at an expenſe which would turn it to his diſadvantage. All the barley ſown was of the Zealand ſtock, and the produce was as follows:

	Pecks.	Qrs. Pecks.	Pints.		Coombs.	Buſhels.	Pecks.	Quarts.
				or on an acre				
1. November	3	0	0		12	2	1	
2. December	3	0	1		12	3	1	1½
3. January	3	1	0		13	0	2	
4. February	2	3	2		11	2	2½	
5. March	2	2	2		10	3	3½	1
6. April	2	0	2		8	3	2½	1

The whole land ſown was ſeventy-two ſquare yards, or little more than two thirds of an acre, and all the ſowings were by the ſide of each other, on the ſame piece of land. Three ſwaths of each ſowing, twelve yards in length, where the ſoil was moſt equal, were threſhed out; and each parcel was dreſſed and meaſured into a ſack ſeparately as ſoon as threſhed[t].

The following experiments were tried by the late Earl of Orford to aſcertain the effect of early ſowing.

The common management of the turnep huſbandry in Norfolk has this evil in it, that the crop is kept for feeding ſo late in the ſpring, that the ſucceeding barley often ſuffers conſiderably, ſometimes to the amount of the value of the turneps.

In 1785, twenty-three acres of turneps being fed off, barley was ſown, three buſhels and a half to the acre on the 7th of february, in the manner of wheat on the ridge; the land having been half ploughed, on to four-furrow ridges. Sharp froſts followed the ſowing, and the ſeed laid five weeks before it appeared; but the crop received injury. It was reaped.

[s] Young's Six Weeks Tour. 277.

[t] Marſo in Young's Annals, 7. 183.—See 4. 187.

The

The produce was five quarters, one buſhel, and one peck on an acre; a very good and ſhort ſample.

In 1787, thirty acres were ſown as before, on turnep land, and on ridge and furrow; beginning on the 6th of February. The produce five quarters one peck on an acre; the ſample ſhort and good, weighing fourteen ſtone ſeven pounds the ſack.

It has been ſaid, if turneps be fed off ſo early, what is to be done for food later? The right time certainly to eat a crop is when it will yield the moſt food, and go the fartheſt. Turneps are often kept till they are good for nothing, and it is no uncommon thing to have them given away to be fed off, for what the farmers call time for barley; that is in april, and even the beginning of may. By this contrivance the turneps are worth nothing, the land is impoveriſhed by them, and there is no chance of good barley. Would it not be much better for the farmer to have other reſources for his ſheep, than run ſuch great hazard, and ſuffer ſuch certain loſs? Would it not be better never to venture barley after late-fed turneps, but to reſerve ſuch land for cabbages? Yet even where lands are fed off by the end of january, and in the caſe of any other preparation for barley, the farmers ſtill leave their lands till the common ſeed-time (april or may), that by giving more tillage, they may get worſe crops[f].

In that part of Eſſex where they underſtand the Barley-culture well, they deſpair of a great crop, if the ſeed is not in the ground in march; but they ſow as ſoon as their lands are dry enough, from the laſt week in february to the middle of april. Mr. Young obſerves on this practice, that early ſowing is a point almoſt ſufficient to turn the ſcale in favour of bad land, in compariſon with good ill-managed. In Suffolk they generally give three ſpring ſtirrings, by which means it is common to ſee them ſowing Barley in may; but no great or good crops can be gained ſo[g]. When Barley is to follow turneps, the beſt farmers in many ſeaſons watch the lucky moment of ploughing their turnep lands, when they will break up into fine mould; one earth will then bring them into crumbling order, and the harrows make them as fine as a garden: in ſuch a caſe the ſeed is got in early, and the land at the ſame time is in good tillage[h].

After all, the ripening of the crop will depend upon the time, not of the ſeeds being ſown, but of their vegetating; and therefore unleſs the ſeaſon be propitious, and the land in proper order, early ſowing of itſelf will avail little[i].

In Norfolk they have a maxim which ſhews that they attended to the foliation of trees as a direction for the proper time of ſowing Barley, long before Linneus recommended it.

> "When the oak puts on his goſſling gray,
> "'Tis time to ſow barley night and day."

That is, when the oak puts on that gray appearance, which it does at the time the buds are burſting, a few days previous to the expanſion of the leaves, no time ſhould be loſt in getting the ſeed-barley into the ground[k].

Mr. Marſhall prefers the flowering of the Hawthorn to the leafing of the Oak for this purpoſe; and ſays, that the Barley ſhould vegetate while the hawthorn is blowing[l].

Soil proper for Barley.

The beſt ſoil for Barley is that which is dry and healthy, rather light than ſtiff, but yet of ſufficient tenacity and ſtrength to retain the moiſture. If the land be poor, it ſhould be dry and warm, and when ſo, will often bear better corn than richer land in a cold and wet ſituation[m]. Much Barley, however is grown on heavy lands, both after wheat and on a fallow.

Succeſſion and Preparation of Land.

Barley uſually ſucceeds wheat or turneps, ſometimes Vetches and other crops, or is put in on a fallow, or on turf. After wheat, the ſoil is winter-fallowed by three ploughings; the firſt lengthways in november; the ſecond croſs in march; the laſt or ſeed-ploughing lengthways. Between the two laſt ploughings the ſoil is harrowed, and the quich, if any, deſtroyed[n].

In Norfolk, when wheat ſowing is finiſhed, the farmer begins to *ſcale* in his wheat-ſtubbles for a winter fallow. If the land lie in narrow work, the ridgelets are ſplit; if in warps the ground is likewiſe ploughed clean, but very ſleet. The beginning of march the land is harrowed, and preſently after the wheat-ſtubbles are taken up by a full-pitch croſs-ploughing: or, if the ſeaſon be wet, and the ſoil heavy, he reverſes the ridges. In april he harrows, and begins ſtirring for barley, with another full-pitch ploughing, lengthways; generally gathering the ſoil either into five-pace or ten-pace warps, in which it lies until ſeed-time; when it is harrowed, rolled, ſown; ploughed ſleet, reverſing the warps, and *ſtading* down the furrows; ſo as to render the entire ſurface as even and level as may be.

After turneps, the ſoil is generally broken up as faſt as the turneps are got off; if early in winter, by ridge-balking; if late, by a plain ploughing. The general practice, if time will permit, is to plough three times; the firſt fleet or ſhallow, the ſecond full-pitch, the laſt a mean depth, with which the ſeed is ploughed in.

But when it is late before the turneps are got off, ſometimes the ground is only ploughed once, and the ſeed ſown above; but more frequently it is broken by three ploughings, as above, though perhaps there is not more than a week to perform them in. Such is the practice in Norfolk, where farmers in general are maſters in the art of cultivating Barley. They ſeem fully aware of the tenderneſs of this plant in its infant ſtate, and of its rootlings being unable to make the proper progreſs in a compact or cold ſoil; they therefore ſtrive by every means in their power to render the ſoil open and pulverous. To this intent it is ſometimes two-furrowed, and even a fourth earth is given, eſpecially in a cold wet ſeaſon.

Nor is this caution confined to turnep-barley, but ſhould be extended more or leſs to ſtubble-barley, which however does not require ſo much care; the ſoil in this caſe being kept open in ſome meaſure by the indigeſted ſtubble, and the roots of graſſes and other weeds, which a turnep-fallow is, or ought to be free from. This perhaps may account for the ſuperiority of ſtubble-barley over that which is produced by a turnep-fallow, though ever ſo well timed and well manured[o].

In ſowing Barley after a fallow they plough three times at leaſt. At the firſt ploughing, the land is laid up in ſmall ridges, and left ſo during the winter, for the froſt to mellow it; the ſecond ploughing ſhould be the beginning of february. In march they ſplit the ridges, and lay the land as flat as poſſible, at the ſame time harrowing it fine. But in ſtrong wet lands they lay it round, and make deep furrows to receive the water[p].

In Eſſex they plough five times, four in the fallow year, throwing the land on to the ridge for winter by the fourth; then they take the firſt opportunity of hard froſts to carry on their compoſts, at the rate of twenty or thirty loads to the acre; theſe are farm-yard dung mixed up with turf; after this, they take the firſt opportunity of the lands being dry enough to plough and ſow the Barley, from the laſt week in february, to the middle of april; but if the ſeed is not in the ground in march, they deſpair of a great crop. This barley-culture is very good; it is an excellent practice to plough and ſow in the ſpring, inſtead of giving preparatory ploughings when the ſeed ſhould be in the earth[q].

When Barley is put on turf, or after lay, as Clover, &c. the turf is generally broken by a winter-fallow, and the ſoil treated in other reſpects, as after wheat. In very light dry ſoils it may be right to break the flag as little as poſſible, provided the graſs be killed; in this caſe they do not break up the turf till after

Chriſtmas. With this proceſs they ſow the Barley above furrow [a].

Barley is ſeldom manured for, except in the laſt caſe, when ſown after lay; after turneps no manure can be requiſite; nor after wheat, if this has been manured for [b]. On a fallow, it is manured for as wheat.

Quantity of Seed, Preparation for, and Method of Sowing.

Many farmers ſow four buſhels of ſeed on an acre, which is too much; and ſome few ſow no more than two buſhels, which is generally allowed to be too little, after all that Mr. Miller has ſaid in favour of thin ſowing. Four buſhels is very general, but in ſome places, three buſhels and a half, and in others three buſhels is the average or medium quantity of Barley ſown.

The following experiments ſeem to confirm Mr. Miller's theory of ſowing thinner on poor ſoils. On an acre of poor ſand worth 3s. 6d. an acre, were ſown two buſhels of barley: on the next adjoining acre, three buſhels: on the next four buſhels. The reſult was, that the crop was beſt from two buſhels, next beſt from three, and the worſt from four.

On ſand worth 7s. an acre

2 buſhels produced	4 ½ quarters.
3 ———	4 ¼
4 ———	3 qu. 7 buſhels [c].

In other ſoils, the produce has been found to be greateſt from the greateſt quantity of ſeed ſown:

	Q.	B.	P.
4 buſhels produced	3	7	0
3 to 4 ———	3	6	0
3 ———	3	0	2 [d].

Again:—

2 to 3 buſhels produced	32 buſhels.
3½ to 4 ———	33
4½ to 5 ———	27 [e].

Which proves that four buſhels is the moſt that ought to be ſown, and that ſcarcely needed a proof.

Brining and liming ſeed-barley previous to ſowing it is a common practice; it is, however, reprobated by ſome, and liming is even thought to be prejudicial. Such as are of the latter opinion, recommend the ſprinkling a little ſoot with the water, to ſecure the ſeed from inſects. It is certain that Barley, which has been wetted for malting, and begins to ſprout, will come up ſooner in a dry ſeed-time; and in ſuch ſeaſon this grain will not only lie long in the ground, but come up and ripen very unequally. To avoid theſe evils, to give the infant Barley an advantage over ſeed-weeds, and a chance of coming to market ſooner, it ſeems a good method to ſteep the ſeed intended for ſowing. This may be either in clean water, or the drainings of the dung heap, in which it may lie covered for twenty-four hours, or even longer, if the land be very dry, and there be no likelihood of rain for ten days. Sow the grain wet from ſteeping, without any thing, or with ſifted wood-aſhes: The ſower muſt put in a fourth or a third more ſeed in bulk than he would of dry grain, the ſeed being ſwelled in that proportion; and he may expect it up in a fortnight at fartheſt [f].

The common method of ſowing Barley is broad-caſt at two ſowings; the firſt harrowed in once, the ſecond twice. In Norfolk, almoſt all the Barley is ſown under-furrow; that is, the ſurface having been ſmoothed by the harrow and roller, the ſeed is ſown and ploughed under with a ſhallow furrow: a method admirably adapted to a light dry ſoil; and indeed to any ſoil which is light enough to produce good Barley, provided it be rendered ſufficiently fine, and the ſeed be not buried too deep. However, if the ſeaſon be wet, and the ſoil cold and heavy, good farmers not unfrequently ſow Barley above, as is the general cuſtom in other counties. And this ſeems to be a reaſonable practice; for in a dry ſpring and light land, ſowing under ſeems moſt eligible; and in a cold ſpring, or when the ſoil is rough with clods, ſowing above appears to be equally good management.

Cultivation after ſeeding.

Whether graſs-ſeeds are ſown over the barley or not, the ſurface is harrowed preſently after the laſt ploughing; and when the Barley is up, it is run over with a light roller, to break the clods, and cloſe the earth about the roots, which is a great advantage to it in dry weather. In heavy lands, if the harrow leaves any clods, they are broken with the clotting-beetle, and if any quich is pulled up, it is deſtroyed [g].

When the Barley has been up three weeks or a month, it is a good way to roll it again with a heavy roller, which will prevent the ſun and air from penetrating the ground to the injury of the roots. It will alſo cauſe the Barley to tiller out, ſo that if the plants be thin, the ground will be filled, and the ſtalks ſtrengthened.

If the blade ſhould grow too rank, mowing is a much better method than feeding it down with ſheep; becauſe the ſcythe take off only the rank tops, but the ſheep being fond of the ſweet end of the ſtalk next the root, will often bite ſo cloſe as to injure its future growth [h].

Drill ſowing.

Grain ſown by hand broadcaſt muſt fall at unequal depths; the ſeeds conſequently ſprout at different times: that which is buried where the earth is moiſt ſoon appears, whilſt ſuch as is near the ſurface lies baking in the heat of the ſun, and does not vegetate till plentiful rains have moiſtened the ſoil: hence an inequality of crop, an accident to which Barley is particularly liable [i]. Of the two common methods of ſowing Barley, ploughing in buries too deep, and that ſown under the harrow is too much expoſed to birds; whereas by the Drill the ſeed is all depoſited regularly at the proper depth [k].

To this advantage peculiar to drilling we may add, the ſaving which is made in the ſeed, and the opportunity which is given by this practice to keep the crop perfectly clean by hoeing. The quantity of ſeed uſed in drilling by different perſons is from ſix pecks to three buſhels; but it is bad economy in general to be too ſparing of ſeed, and it is hardly adviſeable to ſow leſs than two buſhels on an acre. If, however, it ſhould be thought proper to uſe even three buſhels, it will ſtill be a conſiderable ſaving. Drilling indeed cannot ſo well be practiſed on heavy ſoils; but it may have place on thoſe which are light and friable, and therefore peculiarly adapted to Barley. Such ſoils are not injured by horſes going repeatedly upon them, and being almoſt always under command, the horſe-hoe may go over them whenever the farmer is moſt at leiſure.

Dr. Hunter, in his Georgical Eſſays, gives us the following account of an experiment on this ſubject.—"In the ſpring of the year 1769, I ſowed an acre of Barley, in equidiſtant rows, with the drill-plough, in a field which was ſown with the ſame grain, and upon the ſame day, broad-caſt. The broad-caſt took three buſhels per acre; the drill required only ſix pecks. The drills were eight inches aſunder, and the ſeed was lodged about two inches within the ſoil. The drill acre was finiſhed within the hour.

In the courſe of growing the drilled Barley ſeemed greener, and bore a broader leaf than the broad-caſt. When the ears were formed throughout the field, the ear of the drilled Barley was plainly diſtinguiſhed to be near half an inch longer than the broad-caſt, and the grains ſeemed fuller and better fed.

Being at a loſs to acount for this, I dug up ſome roots of both, and found that the pipe of communication between the ſeminal and coronal roots of the

drilled

drilled Barley was considerably longer than in the broad-cast.

The produce of two hundred square yards of the broad-cast and drilled Barley was carefully housed, and afterwards threshed out. The drilled exceeded the other nearly one fifth in measure, and weighed heavier, at the rate of two pounds in the bushel [a].

HOT-BEDS are of general use in these northern parts of Europe, without which we could not enjoy so many of the products of warmer climates as we do now; nor could we have the tables furnished with the several products of the garden, during the winter and spring months, as they are at present in most parts of England, better than perhaps in any other county in Europe: for although we cannot boast of the clemency of our climate, yet England is better furnished with all sorts of esculent plants for the table, much earlier in the season, and in greater quantities, than in the gardens of our neighbours which is owing to our skill in Hot-beds.

The ordinary Hot-beds which are commonly used in the kitchen-gardens, are made with new horse-dung, in the following manner:

1st. There is a quantity of new horse-dung from the stable, in which there should be part of the litter or straw which is commonly used in the stable, but not in too great proportion to the dung, the quantity of this mixture must be according to the length of the bed intended; which, if early in the year, should not be less than one good load for each light; this dung should be thrown up in a heap, mixing therewith a few sea-coal ashes, some leaves of trees, and tan, which will be of service to continue the heat of the dung; it should remain for six or seven days in this heap; then it should be turned over, and the parts well mixed together, and cast into a heap again, where it may continue five or six days longer, by which time it will have acquired a due heat; then in some well sheltered part of the garden, dig a trench in length and width, proportionable to the frames you intend it for; and if the ground be dry, about a foot deep; but if wet, not above six inches; then wheel the dung into the opening, observing to stir every part of it with a fork, and lay it exactly even and smooth through every part of the bed; as also to lay the bottom part of the heap, which is commonly free from litter, upon the surface of the bed; this will prevent the steam from rising so plentifully as it would otherwise do. To prevent this, and the heat from rising so violently as to burn the roots of whatever plants are put into the ground, it will be a very good way to spread a layer of neats dung all over the surface of the horse-dung, which will prevent the mould from burning: if the bed is intended for Cucumbers or Melons, the earth should not be laid all over the bed at first, only a hill of earth should be first laid in the middle of each light on which the plants should be planted, and the remaining space should be filled up from time to time, as the roots of the plants spread; but this is fully explained under those two articles. But if the Hot-bed is intended for other plants, then after the bed is well prepared, it should be left two or three days for the steam to pass off, before the earth is laid upon the dung.

In the making of these Hot-beds, it must be carefully observed to settle the dung close with a fork; and if it be full of long litter, it should be equally trod down close in every part, otherwise it will be subject to heat too violently, and consequently the heat will be much sooner spent, which is one of the greatest dangers these sort of beds may be liable to. During the first week or ten days after the bed is made, cover the glasses but slightly in the night, and in the day-time carefully raise them to let out the steam, which is subject to rise very copiously while the dung is fresh; but as the heat abates, the covering should be increased; otherwise the plants in the beds will be stinted in their growth, if not entirely destroyed. In order to remedy this evil, if the bed be very cold, you must put a pretty good quantity of new hot dung round the sides of it, which will add a fresh heat thereto, and cause it to continue a considerable time after; and as the spring advances, the sun will supply the loss of the dung's heat; but then it will be advisable to lay some mowings of Grass round the sides of the bed, especially if the nights should prove cold, as it often happens in may, which is many times, even at that season, very hurtful to tender plants on Hot-beds.

But although the Hot-bed I have described is what the kitchen-gardeners commonly use, yet those made with tanner's bark are much preferable, especially for all tender exotic plants or fruits, which require an even degree of warmth to be continued for several months, which is what cannot be effected by horse-dung only. The manner of making these beds is as follows:

There must be a trench dug in the earth about three feet deep, if the ground be dry; but if wet, it must not be above a foot or eighteen inches deep at most, and must be raised in proportion above ground, so as to admit of the tan being laid three feet thick. The length must be proportioned to the frames intended to cover it, but should never be less than eleven or twelve feet; but if it is twice that length it will be better, and the width not less than six, which is the least size of these beds to continue the heat. This trench should be bricked up round the sides to the above-mentioned height of three feet, paving the bottom with bricks to prevent the earth mixing with the tan, and should be filled in the spring with fresh tanner's bark (i. e. such as the tanners have lately drawn out of their vats, after they have used it for tanning leather) which should be laid in a round heap for a week or ten days before it is put into the trench, that the moisture may the better drain out of it, which, if detained in too great a quantity, will prevent its fermentation; then put it into the trench, and gently beat it down equally with a dung-fork, but it must not be trodden, which would also prevent its heating, by settling it too close; then you must put on the frame over the bed, covering it with the glasses, and in about ten days or a fortnight it will begin to heat; at which time you may plunge your pots of plants or seed into it, observing not to tread down the bark in doing it.

A bed thus prepared, if the bark be new, and not ground too small, will continue in a good temper of warmth for two or three months; and when you find the heat decline, if you stir up the bark again pretty deep, and mix a load or two of fresh bark amongst the old, it will cause it to heat again, and preserve its warmth two or three months longer. There are many people who lay some hot horse-dung in the bottom of the trench, under the bark, to cause it to heat; but this is what I would never practise, unless I wanted the bed sooner than the bark would heat of it itself, and then I would put but a small quantity of dung at bottom for

[a] Essay xvii. p. 259.

for that is subject to make it heat too violently, and will occasion its losing the heat sooner than ordinary; and there will never be any danger of the bark's heating if it be new, and not put into the trench too wet, though it may sometimes be a fortnight or more before it acquires a sufficient warmth, but then the heat will be more equal and lasting.

The frames which cover these beds should be proportioned to the several plants they are designed to contain: for example, if they are to cover the Ananas or Pine-apple, the back part of the frame should be three feet and a half high, and the lower part fifteen inches, which will be a sufficient declivity to carry off the wet; and the back side will be high enough to contain the large fruiting plants, and the lower side will be sufficient for the shortest plants; so that by placing them regularly according to their height, they will not only have an equal distance from the glasses, but also appear much handsomer to the sight. And although many people make their frames deeper than what I have allotted, yet I am fully persuaded, that where there is but height enough to contain the plants, without bruising their leaves, it is much better than to allow a larger space; for the deeper the frame is made, the less will be the heat of the air inclosed therein, there being no artificial warmth but what the bark affords, which will not heat a large space of air; and as the Pine-apple requires to be constantly kept very warm, in order to ripen the fruit well, so it will be found upon trial, that the depth I have allowed will answer that purpose better than a greater.

But if the bed be intended for taller plants, then the frame must be made in depth proportionable thereto; but if it be for sowing seeds, the frame need not be above fourteen or sixteen inches high at the back, and seven inches deep in the front, by which means the heat will be much greater; and this is commonly the proportion allowed to the frames usually made use of in the kitchen-garden. As to their length, that is generally according to the fancy of the owner; but they commonly contain three lights each, which is in the whole about eleven feet in length, though sometimes they are made to contain four lights; but this is too great a length for the boxes, for the frames thus made are not so hardy to remove as when they are shorter, and are more subject to decay at their corners. Some, indeed, have them to contain but two lights which is very handy for raising Cucumber and Melon plants while young; but this is too short for a Bark-bed, as not allowing room for a proper quantity of bark to continue a warmth for any considerable time, as was before-mentioned; but for the other purposes, one or two such frames are very convenient for common dung-beds.

As to those frames which are made very deep, it is much the better way to have them made to take asunder at the four corners, so that they may be removed with ease; otherwise it will be very difficult to take the frame off, when there is occasion to put in new bark, or take out the old.

[The use of Hot-beds is of very long standing in our gardens; directions for making them having been given by Gerarde in 1597, in his chapter on Cucumbers. But covering them with glasses is of more modern invention, "In the middest of april," says he, "or somewhat sooner, if the weather be any thing "temperate, you shal cause to be made a bed or "bank of hot and new horse dung taken forth of the "stable, and not from the dunghill, of an ell in breadth, "and the like in depth or thicknes, of what length "you please: the which banke you shall cover with "hoopes, and poles, that you may the more conve-"niently cover the whole bed or bancke with mats, "olde painted cloth, strawe or such like, &c. [1].

Hot-beds do not seem to have been known to Thomas Hyll, who published the profitable Arte of Gardening in 1593: for in treating of Melons, Cucumbers and Gourds, "to have them timely, he directs "fine sifted earth to be put into an old basket or "deepe earthen pan, and the same well mixed with "dung, and after to set the same abroad in warme and "sunny daies, and in a smal raine, but at the setting "of the sun, to set the same againe under some co-"vert, whiles untill all the frosts and cold season be "past. And after that when a fair day commeth, "then to set the whole pan or basket to the brim in "the earth."

When glasses for covering Hot-beds were first introduced, I am not able to say. It is certain that they were not known to parkinson, whose two books were published in 1629 and 1640, and that they were in common use long before the end of the last century.

Hot-beds should be in a piece of ground which is dry, and in a sunny exposure, fenced in either by walls or good ship-planks, ten feet high to the north, and six feet high to the south, apart from the rest of the kitchen garden, and as near to the stable dung heap as possible, to avoid labour and dirt in barrowing. Sixty feet in breadth, and a hundred feet in length will be extent sufficient of ground for winter-framing for Mushroom beds; for forcing Asparagus, Peas, Kidney-beans, Strawberries, Radishes, Salad-herbs; early Cucumbers and Melons; Annuals for the flower-garden; Perennials and Shrubs brought forwards, as Pinks, Carnations, Bulbous plants, Lily of the Valley, Roses, Honeysuckles, &c. &c. And under the south fense forcing frames for fruit: the management of which is directed under these several articles.

If the dung for making the Hot-beds be new and strong, there is no necessity for mixing sea-coal ashes, leaves of trees, or tan, as *Mr.* Miller directs: these are of use only for strengthening the heat, and rendering it more durable, when the dung is in some degree exhausted by having been too long in the dung-heap. In fresh dung, they are apt to make the heat too fierce and burning.

Though a trench be usually dug for the Hot-bed, in order to have a part of it underground, yet it is more advisable for early Hot-beds, that must have a lining of fresh dung to keep up the heat, to have them entirely above ground, that they may have the full advantage of the lining.

Hot-beds that are to be covered with common frames should be four feet and a half or five feet in breadth, and three feet and a half or four feet high when made in winter: in spring, the first Hot beds in march may be three feet; the second in april two feet and a half; and the third in may two feet or even eighteen inches towards the end of the month.

The covering of the earth over the dung should be from five to eight or ten inches for most purposes: when pots are to be plunged into the beds, this covering must be of a depth sufficient to reach up to their rims.

Late Hot-beds from the middle or end of april to the end of may, for latter crops of cucumbers and melons, for raising many annual flowers, and for forwarding the less tender sorts of seeds, plants and cuttings, may be covered with bell-glasses, oiled paper, or mats over hoops; of these the oiled paper frames are the best, and answer all the purposes of glass-lights late in the season.

Farther directions respecting Hot-beds and their management may be found in the culture of Cucumbers and Melons, under the article Cucumis.

Hottentot Cherry. See *Cassine Maurocenia*, and *Celastrus lucidus*.]

HOTTONIA. (*So named by Boerhaave, from Peter Hotton, Professor of Botany at Leyden.*)

Lin. gen. n. 203. *Reich.* 216. *Schreb.* 265. *Boerh. Juss.* 95.

Stratiotes. *Vail. mem. acad.* 1719.

Class. 5. 1. Pentandria Monogynia.

Nat. order of *Palmæ*, β.—*Lysimachiæ*, Juss.

GENERIC CHARACTER.

Cal. *Perianth* one-leafed, five-parted: *parts* linear, from erect spreading.

Cor. one-petalled, salver-shaped: *tube* the length of the calyx: *border* five-cleft, flat: *clefts* ovate-oblong, emarginate.

Stam. *Filaments* five, awl-shaped, short, upright, opposite to the clefts of the corolla, and placed on the tube. *Anthers* oblong.

Pist.

[1] Herball, p. 764.

PIST. *Germ* globular-acuminate. *Style* filiform, short. *Stigma* globular.

PER. *Capsule* globular, acuminate, one-celled, placed on the calyx.

SEEDS very many, globular. *Receptacle* globular, large.

ESSENTIAL CHARACTER.

Cor. salver-shaped. *Stam.* placed on the tube of the corolla. *Caps.* one-celled.

Lour. cochinch. 105.
Leaves ovate-oblong, oppofite, quite entire; flowers folitary.

DESCRIPTIONS, &c.

1. The root conſiſts of numerous white capillary fibres, which ſtrike deep into mud. The ſtem is a ſcape, a foot high, ſimple, upright, towards the top roughiſh with little glands, at bottom furniſhed with numerous leaves, whence proceed ſeveral ſtalks, which run out to a conſiderable length through the water, and throw out numerous white fibres. Leaves numerous, generally under water, growing in tufts on the tops of the young ſtems, bending downwards, the pinnas linear and flat. Flowers pale purple or white, with a yellow eye, in ſeveral whorls one above another, forming all together a handſome ſpike. Peduncles as far as ten in number, with a bracte at bottom, and when the flowers are gone off bending downwards[a].

This ſingular plant has the leaves underwater, and the upper part of the flowering ſtem only above; the flowers are beautiful; the leaves afford a refuge, and perhaps nouriſhment to the freſh-water Periwinkle, and other ſmall ſhell-fiſh. It abounds in ditches and marſhes, ſtagnant waters, and ſlow-running ſtreams, flowering in may and june, and continuing a long time in flower. The old writers call it *Millifolium* from the abundance of its leaves; and *Viola*, which was a favourite name for the Stock-Gilliflower and many other plants with handſome flowers, beſides the Violet. In Engliſh, beſides Water Violet, it has the names of Water Milfoil, or Yarrow, and Water Gilliflower; in Dodoen's herbal by Lyte, Water Gilloſer. In German, *Waſſerviole*. In Dutch, *Watervioliter*. In Daniſh, *Vandrollikt*. In Sweditſh, *Vattenrollska*. In French, *Plumeau, Plume d'eau, Plummette, Violette aquatique, Giroflée d'eau, Millefeuille d'eau, Hottone*. In Italian, *Miriofillo aquatich*.

There is a variety with ſmaller leaves[b]. Some flowers have ſix ſtamens, and in that caſe the calyx and corolla are divided into ſix ſegments[c].

2. Stem a finger's length, quite ſimple. Leaves in whorls, frequently eight together, trifid or thrice trifid. Peduncles lateral, from the axils of the leaves, ſolitary, longer than the leaves. The genus is doubtful[d].

Burmann, who found it in the iſland of Ceylon, ſays that the ſtalk is ſlender, jointed, ſimple; that the leaves come out at each joint in a ſtellated form, five, ſix or more together, ſlender, ſhort, pinnately divided; that a ſlender peduncle ſprings from the ſame point, longer than the leaves, bearing a ſingle flower on the top, which has a ſmall five-cleft calyx, and a five-cleft petal, (which in the Hortus Malabaricus is deſcribed and figured as four-cleft) five ſtamens, and one piſtil with a head; and that the fruit is a roundiſh one-celled capſule, containing many ſeeds.

3. Stem ſimple, ſometimes with a branchlet at top. The leaves under water reſemble thoſe of the firſt ſpecies, are in whorls and bipinnate, the ſegments linear, and quite entire; the upper ones are like thoſe of the ſecond ſpecies, three-parted; the ſegments linear-lanceolate, gath-toothed; the floral-leaves in fours, trifid, quite entire, marked with two lines. Spike terminating, three inches long. Flowers ſeſſile, four to each whorl. Calyx the length of the leaves, cylindrical, with awl-ſhaped ſegments. Style longer than the calyx. It differs from the preceding in having the flowers in whorls; from the firſt in the flowers being ſeſſile, and the whorls leafy. Found in the Eaſt-Indies by Burmann[e].

4. Stem commonly quite ſimple, eight inches high, upright. Leaves ſmooth. Flowers purple, axillary, peduncled. Calyx tubular, ſlightly five-cleft, the clefts upright. Anthers twiſted. Stigma turbinate-rounded. Capſule longiſh, two-valved, with many, very ſmall, round, black ſeeds. The flower reſembles that of the ſecond ſpecies, but the leaves are very different. Native of Cochinchina[f].]

PROPAGATION AND CULTURE.

The common Hottonia may be propagated in deep ſtanding waters, by dropping the ſeeds as ſoon as they are ripe, into the water, where they are deſigned to grow; and the ſpring following they will appear, and if they are not diſturbed will ſoon increaſe abundantly. [The other ſorts are not known in Europe, in a living ſtate.

HOVENIA. *(So named by Thunberg, in honour of M. ten Hoven, one of the Privy Counſellors of Holland, one of his patrons, and a great cultivator of exotic plants.)*
Lin. gen. Schreb. n. 375. *Thunb. nov. gen.* 7. *Fl. jap.* 7. *Juſſ.* 381.
Claſſ. 5. 1. Pentandria Monogynia.
Nat. order of *Dumoſæ.—Rhamni*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, hairy at the baſe within, permanent, five-parted: *parts* ovate, reflex, deciduous.
COR. *Petals* five, obovate, very obtuſe, patulous, rolled up, involving the ſtamens, inſerted into the calyx between the ſegments, and of the ſame length with them.
STAM. *Filaments* five, inſerted into the baſe of the calyx, and a little ſhorter. *Anthers* roundiſh, hid within the petals.
PIST. *Germ* ſuperior. *Style* upright, much ſhorter than the calyx. *Stygmas* three, from patulous reflex, blunt.
PER. *Capſule* ovate-globular, three-furrowed, three-celled, three-valved.
SEEDS ſolitary, lens-ſhaped, very ſmooth.
OBS. *Sometimes, but ſeldom, the calyx is four-parted, and there are only four ſtamens.*

DESCRIPTIONS, *&c.*

Root perennial. Stem arboreous, thick, a fathom and half in height. Branches round, ſmooth. Leaves alternate, petioled, ſubcordate, ovate, acuminate, ſerrate, hanging down, nerved, ſmooth, a hand in length. Petiole ſemicylindric, reflex, ſmooth, an inch long. Flowers axillary and terminating, panicled. Panicle dichotomous, compreſſed. Peduncles ſubcylindric, dichotomous, thickening after flowering-time, with a ſweet red pulp, which is eaten by the Japoneſe, and has a taſte ſomewhat like a pear. Pedicels divaricating, bent to and fro, ſmooth, a line in length. The flowers readily fall off.

Native of Japan, near Nagaſaki; flowering from june to auguſt, and ripening the fruit in november and december[a].

Leaves ovate-lanceolate, corymbs terminating, flowers ſuperior.

DESCRIPTIONS, *&c.*

1. This is a vernal plant[b], with terminating flowers[b]. From a ſlender root it produces ſmall, oblong, pointed leaves, ſpreading on the ground in a ring; among theſe, ſlender ſmooth ſtalks ariſe, at the height of two inches forming a joint, and furniſhed with two or three ſmall leaves; here they divide into two, or ſometimes three ſlender branches or peduncles an inch or two in length, and at the end of each a ſingle blue flower.

Native of Virginia, whence it was ſent by John Baniſter[c].

It was introduced by Mr. Archibald Menzies in 1785, and flowers here moſt part of the ſummer[d].

Juſſieu doubts whether the germ be really ſuperior in this, ſince it is certainly inferior in the other ſpecies.

Linnæus had ſuppoſed the ſeeds to be ſolitary. Gærtner imagines, that the globular receptacle falling with the ſeeds, had made Linnæus miſtake it for a ſingle ſeed.

β. The little ſtems are extremely ſlender, half a hand in height, branched, with a pair of narrow, ſhort leaves at each joint; the lower ones ſhaped like thoſe of a very ſmall Alſine. Peduncles axillary, very ſlender, oblong, having each one flower at the top, large in proportion to the ſize of the plant, and blue. Native of Maryland, whence dried ſpecimens of it were brought by Vernon and Krieg.

2. This has leaves in pairs, reſembling thoſe of large Alſine or Chickweed. The flower is of a red purple. Native of Maryland; where it is alſo found with a narrower leaf[e].

Gærtner has a ſpecies (from Sir Joſeph Banks's herbarium) which he calls *H. longifolia*: the capſule of which is ſuperior, bipartile, at the baſe ſurrounded by the four-parted calyx, compreſſed at the top, marked with two grooves; receptacle fungoſe, ſubglobular, pedicelled, fixed to the middle of the partition of each cell, when ripe falling along with the ſeeds; of which there are three of four in each cell, compreſſed a little, having a ridge along the back, and a little umbilical ſcar in the middle of the belly; they are of a very dark brown colour[f].

HOUTTUYNIA. (*So named by Thunberg[g] in honour of Mart. Houttuyn, M.D. of Holland, author of Naturlyke hiſtorie, In fourteen volumes octavo, Amſterdam* 1773 *to* 1783.)
Lin. gen. Schreb. n. 1389. *Thunb. jap.* 12. *Juſſ.* 85. *Giſeke ord. nat.* 127.

SPECIES.

1. Houttuynia cordata.
Lin. ſyſt. 519. *Thunb. jap.* 234. *t.* 26. *act. ſtockh.* 1783. *p.* 149. *t.* 5.

Polypara cochinchinenſis. *Lour. cochinch.* 61.

DESCRIPTIONS, *&c.*

This plant has the habit of Polygonum, with ſtipules as that has[h]. Root annual, fibrous. Stem ſimple, herbaceous, grooved, flexuoſe, upright, a hand, a ſpan, or a foot in height, ſmooth in all its parts. Leaves alternate, petioled, cordate, cuſpidate, entire, paler underneath. Petioles ſtriated, ſtipuled at the baſe, ſhorter than the leaf. Stipules in pairs, faſtened to the petiole at the baſe, oblong, blunt, membranaceous at

[a] Thunberg. [b] Linn. ſyſt. [c] Juſſieu. [d] Mor. hiſt. [e] Hort. kew. [f] Ray hiſt. ſuppl. [g] De fruct. & ſemin. vol. 1. p. 226. [h] Giſeke ord. nat. 128.

the tip, ſhorter by half than the petiole. Flowers from the ſheath of the petiole ſolitary, peduncled. Peduncle the length of the petiole. It is difficult to determine the number of ſtamens in this genus, becauſe there is no calyx, corolla or ſcales to ſeparate the germs. It ought however to be referred to the claſs Polyandria, the ſtamens being ſcattered over an elongated receptacle, among ſeveral germs.

Diſcovered by Thunberg in Japan between Miaco and Jedo, very common in the ditches, and near the towns; flowering in may and june[a].

Loureiro alſo found it, if his Polypara be the ſame plant, in the gardens of Cochinchina, where it is eaten in ſalads, and is eſteemed attenuant, reſolvent and emmenagogue. The leaves are five-nerved in his plant, which they are not in the Houttuynia of Thunberg; but they agree ſo nearly in habit, that we may preſume they are the ſame ſpecies.

Loureiro deſcribes it as annual, with a creeping root; ſtem ſix inches high, upright, grooved; leaves cordate, acuminate, five-nerved, large, quite entire, ſmooth, alternate, ſtrong-ſmelling, on long petioles; flowers lateral, ſolitary, on long upright peduncles; the common corolla (ſpathe) very white and ſpreading. The ſtamens are not confuſedly mixed with the piſtils, but fixed by threes to each of the three ſides of the triangular germ: the germs are alſo diſtinct, with three ſeſſile ſtigmas. Loureiro calls the four leaves at the baſe of the common receptacle the petals; and he names the plant Polypara, becauſe the common corolla (or ſpathe) produces many florets. According to him, each flower has three filiform upright filaments, placed on a partial receptacle, and three ſtigmas: he therefore refers this genus to the order trigynia of the claſs triandria.

HUDSONIA. *(So named by Linnæus, in honour of William Hudſon, apothecary of London, F.R.S. and author of* Flora Anglica 1762 and 1778. 8vo.)

Lin. gen. Reich. n. 657. *Schreb.* 822. *Juſſ.* 162. *Berg. act. holm.* 1778.

Claſſ. 11. 1. Dodecandria Monogynia.

Nat. order of *Bicornes?—Ericæ*, Juſſ.

GENERIC CHARACTER.

PIST. *Germ* ſuperior, ovate. *Style* filiform, the length of the calyx. *Stigma* blunt.

PER. *Capſule* cylindric, ſhorter by half than the calyx, one-celled, three-valved.

SEEDS three, rounded on one ſide, angular on the other.

ESSENTIAL CHARACTER.

Cal. five-leaved (three-leaved *above*, three-parted, *Juſſ.*) tubular. *Cor.* none. (Petals five, very ſmall, *Berg.*) *Stam.* fifteen. *Capſ.* one-celled, three-valved, three-ſeeded.

SPECIES.

1. Hudſonia ericoides.

Lin. ſyſt. 445. *Reich.* 2. 422. *mant.* 74. *Berg. in act. holm.* 1778. *t.* 2. *Pluk. mant.* 88. (Ericæformis ſuffrutex, &c.)

DESCRIPTION, &c.

This is a ſhrub with the appearance and habit of Erica or Heath. Branchlets filiform, ſcattered, imbricate. Leaves ſubulate-acerоſe, hirſute; when tender ſtill more hirſute and hoary, ſo that thoſe on the extreme branchlets ſeem as if they had leafy gems ſcattered over them. Peduncles (from the leafy gems) ſolitary, filiform, longer than the leaves. Calyx erect, pubeſcent. Native of Virginia[a].

HUGONIA. *(So named by Linnæus, in memory of Auguſtus Johannes de Hugo, who travelled in Switzerland with Haller in* 1732, *and aſſiſted him with his herbarium.)*

Lin. gen. n. 831. *Reich.* 896. *Schreb.* 1117. *Cavanill. diſſ.* 3. 177. *Gærtn. t.* 58. *Juſſ.* 275.

Claſſ. 16. 4. Monadelphia Decandria.

Nat. order of *Columniferæ.—Malvaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed: *ſegments* ovate, acute, concave, coriaceous, permanent; the two outer ones larger, (five-leaved, *G.*)

COR. *Petals* five roundiſh, large, emarginate, ſpreading, narrowed at the baſe, fixed at the baſe by ſlender claws to the little pitcher of ſtamens.

STAM. *Filaments* ten, awl-ſhaped, equal, ſhorter than the corolla, connected at bottom into a little pitcher. *Anthers* roundiſh, furrowed, incumbent.

PIST. *Germ* roundiſh. *Styles* five filiform, longer than the ſtamens. *Stigmas* capitate, orbicular, flat.

PER. *Drupe* globular, one-celled: (A berried drupe, *G.*)

SEED. *Nut* globular, deeply ſtriated, ten-celled. *Kernels* oblong, compreſſed, bowed at the back.

OBS. *The two outer ſegments of the perianth are wholly tomentoſe on the outſide; the middle one is alſo tomentoſe, except that part where it is covered by one of the outer ones, and there it is ſmooth and ſhining, as are the two inner ones, which are tomentoſe only at the tip. The filaments were alternately ſhorter in the flower, which I examined. The alternate kernels ſeem frequently to be abortive; hence perhaps Cavanilles makes the fruit to be five-celled. In the drupe which I opened there were more than five kernels.* Sch.

ESSENTIAL CHARACTER.

Five-ſtyled. *Cor.* five-petalled. *Drupe* with a ſtriated nut.

Modira-canni. *Rheed. mal.* 2. 29. *t.* 19.

Spines oppoſite revolute.

DESCRIPTION, &c.

This is a tree with an irregular bark. Branchlets ſhort, alternate, ſpreading, leafy at the end. Leaves oval, quite entire, ſmooth, petioled, cluſtered. Flowers ſeveral, from the ends of the branches, in cluſters, white. Tendrils or ſpines two, on each of the branchlets, ſhort, rigid, parallel to the branches, below the leaves. Perianth five-leaved. Anthers twin. Germ ovate, within the little pitcher formed by the lower part of the filaments[a].

The fruit is a berried, ſpherical, ſucculent drupe; the ſkin is very thin, papery, tough, white, with a very poliſhed ſhining ſurface; the pulp is ſucculent, but diſappears in time; the ſhell is bony, ſpherical, deeply ſtriated, and ten-celled. There is a ſingle oblong ſeed in each cell, drawn to a point at both ends, arched on the back, thickiſh, flat on the ſides, wedge-form, compreſſed, pale[b].

Native of the Eaſt Indies.

DESCRIPTION, *&c.*

Root perennial. Stems weak and twining, not climbing by tendrils, but aſcending a prop, trees or ſhrubs in a ſpiral, always with the ſun, that is from right to left, or from eaſt to weſt by the ſouth; this direction it has in common with Tamus or Black Bryony, Lonicera or Honeyſuckle, and ſeveral others; but more turn the contrary way, or from left to right, as Phaſeolus or Kidney Beans, and ſeveral other leguminous plants, Convolvulus, &c. &c.[a] Theſe ſtems are angular, ſtriated, and rugged with very minute prickles. Leaves oppoſite in pairs, (or ſometimes in threes) the upper ones heart-ſhaped, the lower three-lobed, (or ſometimes five-lobed) ſerrate, dark green above, pale green beneath, on long petioles; which, as well as the leaves themſelves, are rugged with minute prickles. Stipules two or four, cordate, bifid, at each joint. Flowers greeniſh yellow; the males on branched peduncles; the females on a diſtinct plant, peduncled, in pairs, in form of a cone or ſtrobile[b], compoſed of ovate, membranaceous ſcales, tubular from being rolled in at the baſe, and two-flowered, each containing one (ſometimes two) ſeed, of a brown bay colour, of a globular form a little flatted, ſurrounded with a ſharp rim, and compreſſed at the tip. It is covered with three coats; the outer membranaceous and wrinkled, the middle cruſtaceous and thin, the inner membranaceous. The embryo is ſpiral and inverted[c].

Native of moſt parts of Europe, in hedges; alſo of Japan; flowering with us in june.

Hops in German are called *Hopfen*; in Dutch, *Hoppe*: in Daniſh and Sweediſh, *Humle*; in French, *le Houblon*; in Italian, *Lupulo*: in Spaniſh, *Hombrecillo, Iroblon, lupulo, lupio, vidarria*; in Portugueze, *Lupulo, lupara, bombrezilbo, ſinoura, ſebo*; in Ruſſian and all the Sclavonian dialects, *Chmel*; in the Tartarian, *Kumulak, Kumula, Umula*; in Perſian *Hymel*.

The young ſhoots are eaten early in the ſpring as Aſparagus, and are ſold under the name of Hop-tops; they are ſaid to be diuretic, and to be good againſt the ſcurvy, taken in an infuſion. The herb will dye wool yellow. From the ſtalks a ſtrong cloth is made in Sweden: for this purpoſe they muſt be gathered in autumn, ſoaked in water all winter; and in march, after being dried in a ſtove, they are dreſſed like flax[d]. They require a longer time to rot than flax, and if not completely macerated, the woody part will not ſeparate, nor the cloth prove white or fine.

The Society for encouragement of Arts, Manufactures and Commerce at London offered premiums, in the year 1760, for cloth made from Hop-ſtalks, or binds. The year following Mr. Cookſey produced ſome ſpecimens of cloth, and was of opinion that it would anſwer very well the purpoſe of fine ſacking, and coarſe bagging for hops. He had kept the material too long under water; and found that at the end of ſix weeks or two months, the binds afforded filaments ſufficiently fine and ſtrong for any purpoſe[e]. In 1791, Mr. John Lockett of Donnington near Newbury in Berkſhire had the premium adjudged to him for cloth made from theſe ſtalks or Hop-Vines, as they are here called. They were cut in lengths of about two or three feet; put into a furnace, in which was ſome lie that linen had been boiled in for bleaching; and then boiled, till the rind ſeparated from the ſtalk eaſily. When cool, they ſtripe ſo freely, that children might do it; and the yield was great in proportion to the quantity of ſtalks. The ſame method was then followed as in working hemp or flax; but it is much more ſtubborn than either, and therefore not ſo well adapted to making fine cloth: the fibres alſo are ſo united with a very adherent matter, that they do not eaſily ſeparate; but for ſacks, cordage, &c. it may be of great ſervice.

Some of it was hackled while it was wet, ſoon after it was taken off, but it did not ſeparate the fibres. Carding ſeems to work it beſt, and to make it like cotton. Of the piece of cloth ſent the warp was hackled, and the woof carded[f].

A decoction of the roots of Hops, from one to two ounces; or an extract from them, to the quantity of twenty or thirty grains, is ſaid to be ſudorific, and to anſwer the purpoſes of Sarſaparilla[g]. Both theſe and the ſtrobiles have a balſamic principle, and are thought to be ſerviceable in removing obſtructions, correcting the viſcidity of the lymph, opening the pores of the ſkin, cleanſing the kidneys, &c. But the principal uſe of the latter in Britain and other northern countries, is in brewing beer, to prevent it from turning ſour. Haller, from Iſidorus, ſays that the firſt experiment for this purpoſe was made in Italy.

The uſe of Hops for preſerving beer, and the culture of the plant were introduced into England from Flanders. The year aſſigned is 1524, the 15th of Henry VIII.[h] But under Henry VI. the Parliament petitioned againſt the uſe of them.[i] Fitzherbert in 1534 makes no mention of them; but Tuſſer in 1562 gives many directions for their culture[k], which was new in his time; for although they probably began to be uſed after the expedition of King Henry VIII.[l] againſt Tournay, yet like moſt noveities they were at firſt much oppoſed, and were doubtleſs for ſome time chiefly imported; for ſo late as the year 1695, five hundred and ten hundred weight was imported from Flanders and Holland[m].

The firſt treatiſe written expreſsly on the culture of Hops in Engliſh was by Reynolde Scot, printed in 1574, and a ſecond time in 1576; it is entitled "A perfite platforme of a Hoppe Garden." Lond. qu. black letter: pages 63.

He complains, that "the Flemmings envie our "practice herin, who altogither tende their owne pro- "fite, ſeeking to impownde us in the ignoraunce of "our commodities, to cramme us with the wares and "fruites of their Countrie, and to doe anye thing that "myght put impediment to this purpoſe, dazeling us "with the diſcommendation of our ſoyle, obſcuring "and falſifying the order of this myſterie, ſending us "into Flaunders as farre as Poppering, for that which "we may finde at home in our owne backſides."

Gervaſe Markham, in his farewell to Huſbandry 1631, has a chapter on barren grounds, and on making them fruitful to bear Hops. l. 2 op. 109. ed. 8. 1664.

It appears from our old herbaliſts Gerarde and Parkinſon, that Ale and Beer were different liquors; the firſt being malt-liquor without, and the ſecond with Hops.—"The Ale," ſays the latter of theſe authors (1640) "which our forefathers were accuſtomed only

" to drink, being a kind of thicker drink than beere, " is now almoſt quite left off to be made, the uſe of " Hoppes to be put therein, altering the quality " thereof, to be much more healthfull, or rather phy- " ſicall, to preſerve the body from the repletion of " groſſe humours, which the Ale engendred."

Walter Blith, in his Engliſh Improver Improved, 1649; third, edition, 1653, p. 240, has a chapter upon improvement by plantations of Hops, &c. He obſerves that " Hops were then grown to be a nationall " commodity: but that it was not many years ſince " the famous City of London petitioned the Parliament " of England againſt two anuſancies—and theſe were, " Newcaſtle coals, in regard of their ſtench, &c. and " Hops in regard they would ſpoyl the taſt of drink, " and endanger the people: and had the Parliament " been no wiſer than they, we had been in a mea- " ſure pined, and in a great meaſure ſtarved, which " is juſt anſwerable to the principles of thoſe men " who cry down all devices or ingenious diſcoveries, " as projects, and thereby ſtifle and choak improve- " ments."

He has eight pages in quarto upon the land beſt for Hops, and the beſt ſets for planting; the manner of planting and cultivating them; and the profit accruing from them.

Samuel Hartlib, Eſq. in the Compleat Huſbandman, 1659, ſays that in Queen Elizabeth's time we had Hopps from the Low Countries; and that " the " Frenchman who writes the Treaſure Politick ſaith, " that it's one of the great deficiencies of England, " that Hopps will not grow, whereas now it is known, " that they are the beſt in the world."

Robert Sharrock, fellow of New College, Oxford, in his hiſtory of the Propagation and Improvement of Vegetables, Oxf. 1660. 8°—2d edition 1672, p. 86, &c. gives inſtructions for the planting and management of Hops, from Blith and the Farnham practice.

Mr. Worlidge, in his Syſtema Agriculturæ, or Myſtery of Huſbandry diſcovered, 1668 folio, is very copious in his directions for the tillage of Hops. He ſays, we had not then enough planted to ſerve the kingdom, but yearly made uſe of Flemiſh Hops, nothing near ſo good as our own[1].

Mortimer, in his whole Art of Huſbandry, 1706, 8°. gives ample directions for the planting, culture, picking, drying, and bagging of Hops[2]. The beſt inſtructions relative to brewing are alſo to be found in this work[3].

The authors above mentioned bring down the culture of Hops to the time of Mr. Miller, who has confined himſelf chiefly to the method which is followed in the county of Kent, where they were firſt adopted, with moſt of our improvements in huſbandry, from Flanders. There are other treatiſes on the ſubject; but I have mentioned thoſe only which I have had an opportunity of conſulting.

Blith's directions are chiefly abridged from Scot's diffuſive treatiſe. Sharrock has followed Blith, with additions from the practice of the Farnham Hop-Maſters. Markham is very brief on the ſubject. Worlidge is ſufficiently copious, and appears to have taken much from Scot the original fountain. Mortimer has tranſcribed from Worlidge almoſt literally, the greater part of what he has written on the ſubject.

Ground-Ivy, called alſo Ale-hoof or Tun-hoof (Glechoma hederacea) was generally uſed for preſerving Beer, before the introduction of Hops. And ſince they have been introduced, many plants are ſaid to ſerve as ſuccedaneums when Hops are dear: as the roots of Ginger and Gentian; the ſeeds of Coloquintida; and the herbs of Horehound, Wormwood, Broom, Cardunus benedictus, Centaurea Calcitrapa or Star-Thiſtle, Quaſſia, Marſh-Trefoil or Buckbean (Menyanthes trifoliata), &c. The laſt particularly is recommended as a much more wholeſome bitter than Hops, in the proportion of two ounces, where a pound of the latter is uſed[4]. But all public brewers are enjoined under a ſevere penalty to uſe no other bitter than Hops for their malt liquors.

It is a general opinion among the Hop-planters, that the plants which bear the male flowers, or the Wild Hops as they call them, are of no ſervice in ſecuring or increaſing the crop; they are therefore commonly caſt out. It would be well however if ſome accurate experiments were made on this ſubject.]

PROPAGATION AND CULTURE.

There being the greateſt plantation of Hops in Kent that are in any county in England, it is very probable, that their method of planting and ordering them ſhould be the beſt.

As for the choice of their Hop-grounds, they eſteem the richeſt and ſtrongeſt grounds as the moſt proper: they chuſe a warm dry ſoil, that has a good depth of hazel mould; and if it be rocky within two or three feet of the ſurface, the Hops will proſper well: but they will by no means thrive on a ſtiff, clay, or ſpongy wet land.

If it may be, chuſe a piece of meadow or lay ground to plant Hops on, ſuch as has not been tilled or ſown with other crops for many years, or an old decayed orchard; for land that is worn out by long bearing of Corn, will require abundance of dung to bring it into any tolerable condition to bear a crop of Hops. The Kentiſh planters accounting a new land beſt for Hops, they plant their Hop-gardens with Apple-trees at a large diſtance, and with Cherry-trees between; and when the land has done its beſt for Hops, which they reckon it will in about ten years, the trees may begin to bear. The Cherry-trees laſt about thirty years, and by the time the Apple-trees are large, they cut down the Cherry-trees.

The Eſſex planters account a moory land the propereſt for Hops, though there are ſeveral other ſorts of ſoil that are eſteemed very good.

Some account that a land which has a roſſelly top, and a brick earth bottom, the beſt; a true roſſel or light ſand, is what they generally plant in, whether it be white or black.

Moory land is of different ſorts, ſome being ſtrong and heavy, ſo as to crack in ſummer; and ſome ſo light, that in dry ſeaſons it will blow away with the wind; and ſome are of a middle conſiſtence, being compoſed of both.

Theſe moors for goodneſs and value, are according to the nature and goodneſs of the ſoil that is underneath them; which being flung up upon the ſurface, will make a very good mixture, it being beſt to fling the under ſoil downward for Hops, becauſe they naturally root downwards, ſometimes four or five yards deep, and therefore the deepeſt and richeſt ſoil is beſt for them.

Few are acquainted with the value of moors, becauſe they do not ſearch into the bottom of them, by reaſon of the expenſiveneſs of doing it, and the difficulty of carrying off the water.

If the land be moiſt, it ought to be laid up in high ridges, and to be well drained, and the drains kept clear and open, eſpecially in winter, that the water do not rot or too much chill the roots.

If the land be ſour or cold, it will be very much helped by burning it; and if the haulm and ſtrings of the Hops be burnt every year, and ſome of the paring or ſides of the garden or other earth be laid on them as they burn, and then more haulm be laid over that, and ſo continued layer upon layer, it will make an excellent compoſt to make the hills with.

As to the ſituation of a Hop-ground, one that inclines to the ſouth or weſt is the moſt eligible; but if it be expoſed to the north-eaſt or ſouth-weſt winds, there ſhould be a ſhelter of ſome trees at a diſtance; becauſe the north-eaſt winds are apt to nip the tender ſhoots in the ſpring, and the ſouth-weſt frequently break and blow the poles at the latter end of the ſummer, and very much endanger the Hops.

Hops require to be planted in an open ſituation, that the air may freely paſs round and between them to dry up and diſſipate the moiſture, whereby they will not be ſo ſubject to fire-blaſts, which often deſtroy the mid-

tles of large plantations, while the outſides remain unhurt.

As for the preparation of the ground for planting, it ſhould, the winter before, be ploughed and harrowed even; and then lay upon it in heaps a good quantity of freſh rich earth, or well rotted dung and earth mixed together, ſufficient to put half a buſhel in every hole to plant the Hops in, unleſs the natural ground be very freſh and good.

Then lay a line acroſs it from the hedge, in which knots have been tied, at the diſtance you deſign your Hop-hills to be at, about eight or nine feet diſtance the whole length of the ground, and place a ſharp pointed ſtick at every knot; then lay aſide the line, and with two forked ſticks of about eight or nine feet long, you may from the firſt row ſet out the whole ground, by applying the two forks or two of the ſticks which were firſt ſet up, and placing another row at the ends, where the forked ſticks meet triangularwiſe; then you ſhould dig a hole at every ſtick about a foot and a half wide, and fill it full of the good earth you brought in.

If you plough the ground with horſes between the hills, it will be beſt to plant them in ſquares checquerwiſe; but the quincunx form is the moſt beautiful, and it will alſo be better for the Hop; but if the ground is intended to be cultivated by the breaſt-plough, it will be beſt to plant them in ſquares; but which way ſoever you make uſe of, a ſtake ſhould be ſtuck down at all the places where the hills are to be made.

Perſons ought to be very curious in the choice of the plants and ſets, as to the kind of the Hop; for if the Hop-garden be planted with a mixture of two or three ſorts of Hops that ripen at different times, it will cauſe a great deal of trouble, and be a great detriment to the owner.

The two beſt ſorts are the white and the gray bind; the latter is a large ſquare Hop, more hardy, and is the more plentiful bearer, but ripens later than the former.

There is alſo another ſort of the white bind, which ripens in a week or ten days before the common; but this is tenderer, and a leſs plentiful bearer, but it has this advantage, it comes firſt to market.

But if three grounds, or three diſtant parts of one ground, be planted with theſe three ſorts, there will be this conveniency, that they may be picked ſucceſſively as they become ripe.

The ſets ought to be procured out of grounds that are entirely of the ſame ſorts you would have, they ſhould be five or ſix inches long, with three or more joints or buds on them, all the old bind and hollow part of the ſet being cut off.

If there be a ſort of Hop you value, and would increaſe plants and ſets from, the ſuperfluous binds may be laid down when the Hops are tied, cutting off the tops, and burying them in the hill; or when the Hops are dreſſed, all the cuttings may be ſaved, and laid in rows in a bed of good earth; for almoſt every part will grow, and become a good ſet the next ſpring.

Some have tried to raiſe a Hop-ground by ſowing ſeeds, but that turns to no account, becauſe that way is not only tedious, but the Hops ſo produced are commonly of different kinds, and many of them wild and barren.

As to the ſeaſons of planting Hops, the Kentiſh planters beſt approve the months of octlober and march, both which ſucceed very well; but the common ſets are not to be had in octlober, unleſs from ſome ground that is to be digged up and deſtroyed; and likewiſe there is ſome danger that the ſets may be rotted, if the winter prove very wet; but the moſt uſual time of procuring them is in march, when the Hops are cut and dreſſed.

As to the manner of planting the ſets, you ſhould put two or three good ſets in every hole with a ſetting ſtick, at about four inches diſtance, placing them ſloping; they muſt ſtand even with the ſurface of the ground; let them be preſſed cloſe with the hand, and covered with fine earth, and a ſtick ſhould be placed on each ſide the hill to ſecure it.

The ground being thus planted, all that is to be done more that ſummer, is to keep the hills clear from weeds, and to horſe-hoe the ground about the month of may, gathering up the ſtones, if more are turned up by ploughing, and to raiſe a ſmall hill round about the plants; and in june you muſt twiſt the young binds or branches together in a bunch or knot, for if they are tied up to ſmall poles the firſt year, in order to have a few Hops from them, it will not countervail the weakening the plants.

A mixture of compoſt or dung being prepared for your Hop-ground, the beſt time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the Hops, nor furrow the ground: if this be not done then, you muſt be obliged to wait till the froſt has hardened the ground, ſo that it will bear the dung-cart; and this is alſo the time to carry on your new poles, to recruit thoſe that are decayed, and to be caſt out every year.

If you have good ſtore of dung, the beſt way will be to ſpread it in the alleys all over the ground, and to dig or plough it in the winter following. The quantity they will require, will be forty loads to an acre, reckoning about thirty buſhels to the load.

If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the reſt in another, or a third; for there is no occaſion to dung the ground after this manner, oftener than once in two or three years.

Thoſe who have but a ſmall quantity of dung, uſually content themſelves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about november, or in the ſpring; which laſt ſome account the beſt time, when the Hops are dreſſed, to cover them after they are cut; but if it be done at this time, the compoſt or dung ought to be very well rotted and fine.

As to the dreſſing of the Hops, when the Hop-ground is dug or ploughed in january or february, the earth about the hills, and very near them, ought to be taken away with a ſpade, that you may come the more conveniently at the ſtock to cut it.

About the end of february, if the Hops were planted the ſpring before, or if the ground be weak, they ought to be dreſſed in dry weather; but elſe, if the ground be ſtrong and in perfection, the middle of march will be a good time; and the latter end of march, if it be apt to produce over-rank binds, or the beginning of april, may be ſoon enough.

Then having with an iron picker cleared away all the earth out of the hills, ſo as to make the ſtock bare to the principal roots, with a ſharp *knife* you muſt cut off all the ſhoots which grew up with the binds the laſt year; and alſo the young ſuckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the ſtock lower than the other, and alſo to cut that part low, that was left higheſt the preceding year. By purſuing this method, you may expect to have ſtronger buds, and alſo keep the hill in good order.

In dreſſing thoſe Hops that have been planted the year before, you ought to cut off both the dead tops, and the young ſuckers which have ſprung up from the ſets, and alſo to cover the ſtocks with fine earth a finger's length in thickneſs.

About the middle of april the Hops are to be poled, when the ſhoots begin to ſprout up; the poles muſt be ſet to the hills deep into the ground, with a ſquare iron pitcher or crow, that they may the better endure the wind; three poles are ſufficient for one hill. Theſe ſhould be placed as near the hills as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a ſpace between two poles ought to be left open to the ſouth, to admit the ſun beams.

The poles ought to be in length ſixteen or twenty feet, more or leſs, according as the ground is in ſtrength; and great care is to be taken not to overpole a young or weak ground, for that will draw the ſtock too much, and weaken it. If a ground be overpoled, you are not to expect a good crop from it: for the branches which bear the Hops will grow

very little, till the binds have over reached the poles, which they cannot do when the poles are too long. Two ſmall poles are ſufficient for a ground that is young.

If you wait till the ſprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largeſt poles; but if you ſtay till they are ſo long as to fall into the alleys, it will be injurious to them, becauſe they will entangle one with another, and will not claſp about the pole ſo readily.

Maple or Aſpen poles are accounted the beſt for Hops, on which they are thought to proſper beſt, becauſe of their warmth; or elſe, becauſe the climbing of the Hop is furthered by means of the roughneſs of the bark. But for laſtingneſs, Aſhen or Willow poles are preferable; but Cheſtnut poles are the moſt durable of all.

If, after the Hops are grown up, you find any of them have been under-poled, taller poles may be placed near thoſe that are too ſhort, to receive the binds from them.

As to the tying of Hops, the buds that do not claſp of themſelves to the neareſt pole when they are grown to three or four feet high, muſt be guided to it by the hand, turning them to the ſun, whoſe courſe they will always follow. They muſt be bound with withered Ruſhes, but not ſo cloſe as to hinder them from climbing up the pole.

This you muſt continue to do till all the poles are furniſhed with binds, of which two or three are enough for a pole; and all the ſprouts and binds that you have no occaſion for, are to be plucked up; but if the ground be young, then none of theſe uſeleſs binds ſhould be plucked up, but ſhould be wrapt up together in the middle of the hill.

When the bins are grown beyond the reach of your hands, if they forſake the poles, you ſhould make uſe of a ſtand ladder in tying them up.

Some adviſe, that if the binds be very ſtrong, and overgrow the poles very much, you ſtrike off their heads with a long ſwitch, to increaſe their branching below.

Towards the latter end of may, when you have made an end of tying them, the ground muſt have the ſummer ploughing or digging, which is done by caſting up with the ſpade ſome fine earth into every hill, and a month after it muſt be again repeated, and the hills made up to a convenient bigneſs.

It is not at all to be doubted, but that a thorough watering would be of very great advantage to Hops in a hot dry ſummer; but it is ſo much charge and trouble to do this, that unleſs you have a ſtream at hand to flow the ground, it is ſcarce practicable.

When the Hops blow, you ſhould obſerve if there be any wild barren hills among them, and mark them, by driving a ſharpened ſtick into every ſuch hill, that they may be digged up and replanted.

Hops as well as other vegetables, are liable to diſtempers and diſaſters, and among the reſt to the ſen. The Rev. Dr. Hales, in his excellent Treatiſe of Vegetable Statics, treating of Hops gives us the following account of the ſtate of Hops in Kent in the year 1725, that he received from Mr. Auſten of Canterbury, which is as follows:

In mid april not half the ſhoots appeared above ground, ſo that the planters knew not how to pole them to the beſt advantage.

This defect of the ſhoot, upon opening the hills, was found to be owing to the multitude and variety of vermin that lay preying upon the roots; the increaſe of which, was imputed to the long and almoſt uninterrupted ſeries of dry weather for three months before. Towards the end of april many of the Hop-vines were infeſted with flies.

About the 20th of may there was a very unequal appearance, ſome Vines being run ſeven feet, others not above three or four; ſome juſt tied to the poles, and ſome not viſible; and this diſproportionate inequality in their ſize, continued through the whole time of their growth.

The flies now appeared upon the leaves of the forwardeſt Vines, but not in ſuch numbers here, as they did in moſt other places. About the middle of june the flies increaſed, yet not ſo as to endanger the crop; but in diſtant plantations they were exceedingly multiplied, ſo as to ſwarm towards the end of the month.

June the 27th ſome ſpecks of ſen appeared. From this time to the 9th of july was very dry weather. At this time, when it was ſaid, that the Hops in moſt parts of the kingdom looked black and ſickly, and ſeemed paſt recovery, ours held it out pretty well, in the opinion of the moſt ſkilful planters.

The great leaves were indeed diſcoloured, and a little withered, and the ſen was ſomewhat increaſed. From the 9th of july to the 23d, the ſen increaſed a great deal; but the flies and lice decreaſed, it raining much daily. In a week more the ſen which ſeemed to be almoſt at a ſtand, was conſiderably increaſed, eſpecially in thoſe grounds were it firſt appeared.

About the middle of auguſt the Vines had done growing both in ſtem and branch, and the forwardeſt began to be in the Hop, the reſt in bloom; the ſen continued ſpreading where it was not before perceived, and not only the leaves, but many of the burs were alſo tainted with it.

About the 20th of auguſt ſome of the Hops were infected with the ſen, and whole branches corrupted by it. Half the plantations had pretty well eſcaped hitherto, and from this time the ſen increaſed but little; but ſeveral days wind and rain the following week ſo diſtorted them, that many of them began to dwindle, and at laſt came to nothing; and of thoſe that then remained in bloom, ſome never turned to Hops; and of the reſt which did, many of them were ſo ſmall, that they very little exceeded the bigneſs of a good thriving bur.

We did not begin to pick till the 8th of ſeptember, which is eighteen days later than we began the year before; the crop was little above two hundred on an acre round, and not good. The beſt Hops ſold this year at Way-hill, for 16l. the hundred.

Dr. Hales gives us an account of the following experiment that he made on Hop-vines. He tells us, that in july he cut off two thriving Hop-vines near the ground, in a thick ſhady part of the garden, the pole ſtill ſtanding; he ſtripped the leaves off from one of theſe Vines, and ſet their ſtems in known quantities of water in little bottles; that with leaves imbibed in a twelve hours day four ounces, and that without leaves three-fourths of an ounce.

He took another Hop-pole with its Vines on it, and carried it out of the Hop-ground into a free and open expoſure; theſe imbibed and perſpired as much more as the former in the Hop-ground, which is, doubtleſs, the reaſon why the Hop-vines on the outſides of plantations, where they are moſt expoſed to the air, are ſhort and poor, in compariſon of thoſe in the middle of the ground, viz. becauſe being much dried, their fibres harden ſooner, and therefore they cannot grow ſo kindly as thoſe in the middle of the ground, which, by ſhade, are always kept moiſter, and more ductile.

The ſame curious author proceeds as follows: Now there being 1000 hills in an acre of Hop-ground, and each hill having three poles, and each pole three Vines, the number of Vines will be 9000, each of which perſpiring four ounces, the ſum of all the ounces perſpired by an acre in twelve hours day will be 36000 ounces = 15750000 grains = 62007 cube inches, or 220 gallons, which divided by 6272640, the number of ſquare inches in an acre, it will be found, that the quantity of liquor perſpired by all the Hop-vines will be equal to an area of liquor as broad as an acre, and $\frac{1}{100}$ part of an inch deep, beſides what evaporated from the earth.

And this quantity of moiſture, in a kindly ſtate of the air, if daily carried off, is a ſufficient quantity to keep the Hops in a healthy ſtate; but in a rainy moiſt ſtate of air, without a due mixture of dry weather, too much moiſture hovers about the Hops, ſo as to hinder, in ſome meaſure, the kindly perſpiration of the leaves, whereby the ſtagnating ſap corrupts, and breeds

mouldy

mouldy ſen, which often ſpoils vaſt quantities of flouriſhing Hop-grounds.

This was the caſe in the year 1723, when for ten or fourteen days almoſt continual rains fell, about the latter half of july, after four months dry weather, upon which the moſt flouriſhing and promiſing Hops were all infected with mould, or ſen, in their leaves and fruit, while the then poor and unpromiſing Hops eſcaped, and produced plenty, becauſe they, being ſmall, did not perſpire ſo great a quantity as others, nor did they confine the preſpired vapour, ſo much as the large thriving Vines did in their ſhady thickets.

This rain on the then warm earth, made the Graſs ſhoot out as faſt as if it were in a hot-bed, and the Apples grew ſo precipitately, that they were of a flaſhy conſtitution, ſo as to rot more remarkably than had ever been remembered.

The planters obſerve, That when a mould, or ſen, has once ſeized any part of the ground, it ſoon runs over the whole, and that the Graſs, and other herbs under the Hops, are infected with it, probably, becauſe the ſmall ſeeds of this quick-growing mould, which ſoon come to maturity, are blown over the whole ground; which ſpreading of the ſeed may be the reaſon why ſome grounds are infected with ſen for ſeveral years ſucceſſively, viz. from the ſeeds of the laſt year's ſen. Might it not then be adviſed to burn the fenny Hop-vines, as ſoon as the Hops are picked, in hopes thereby to deſtroy ſome of the ſeed of the mould?

Mr. Auſten, or Canterbury, obſerves ſen to be more fatal to thoſe grounds that are low and ſheltered, than to the high and open grounds, to thoſe that are ſhelving to the north, than to thoſe ſhelving to the ſouth; to the middle of grounds than to the outſides; to the dry and gentle grounds, than to the moiſt and ſtiff grounds.

This was very apparent throughout the plantations where the land had the ſame workmanſhip and help beſtowed upon it, and was wrought at the ſame time. But if in either of theſe caſes there was a difference, it had a different effect, and the low and gentle grounds, that lay neglected, were then ſeen leſs diſtempered than the open and moiſt, which were carefully managed and looked after.

The honey dews are obſerved to come about the 11th of june, which, by the middle of july, turn the leaves black, and make them ſtink.

Dr. Hales relates, That in the month of july (the ſeaſon for fire-blaſts, as the planters call them) he has ſeen the Vines in the middle of the Hop-ground ſcorched up almoſt from one end of a large ground to the other, when a hot gleam of ſun-ſhine has come immediately after a ſhower of rain, at which time vapours are all ſeen with the naked eye, but eſpecially with reflecting teleſcopes, to aſcend ſo plentifully as to make a clear and diſtinct object become immediately very dim and tremulous; nor was there any dry gravelly vein in the ground along the courſe of this ſcorch; it was therefore, probably, owing to the much greater quantity of ſcorching vapours in the middle, than the outſides of the ground, and that being a denſer medium, it was much hotter than a more rare medium.

And, perhaps, the great volume of aſcending vapours might make the ſun-beams converge a little towards the middle of the ground, that being a denſer medium, and thereby increaſe the heat conſiderably; for he obſerved, That the courſe of the ſcorched Hops was in lines at right angles to the ſun-beams about eleven o'clock, at which time the hot gleam was.

The Hop-ground was in a valley which ran from ſouth-weſt to north-eaſt, and to the beſt of his remembrance, there was but little wind, and that in the courſe of the ſcorch; but had there been ſome other gentle wind, either north or ſouth, it is not improbable but that the north wind gently blowing the volume of riſing wreak on the ſouth ſide of the ground, that ſide might have been moſt ſcorched, and ſo vice verſa.

As to particular fire-blaſts, which ſcorch here and there a few Hop-vines, or one or two branches of a tree, without damaging the next adjoining, what aſtronomers obſerve, may hint to us no very improbable cauſe of it, viz. They frequently obſerve (eſpecially with reflecting teleſcopes) ſmall ſeparate portions of pellucid vapours floating in the air, which, though not viſible to the naked eye, are yet conſiderably denſer than the circumambient air; and vapours of ſuch a degree of denſity may very probably either acquire ſuch a ſcalding heat from the ſun as will ſcorch what plants they touch, eſpecially the more tender.

(An effect which the gardeners about London have too often found to their coſt, when they have incautiouſly put bell-glaſſes over their Cauliflowers early in a froſty morning, before the dew was evaporated off them; which dew, being raiſed by the ſun's warmth, and confined within the glaſs, did there form a denſe, tranſparent, ſcalding vapour, which burned and killed the plants:)

Or, perhaps, the upper or lower ſurface of theſe tranſparent, ſeparate, flying volumes of vapours, may, among the many forms they revolve into, ſometimes approach ſo near to an hemiſphere, or hemicylinder, as thereby to make the ſun-beams converge, ſo as often to ſcorch the more tender plants they ſhall fall on, and ſometimes alſo parts of the more hardy plants and trees, in proportion to the greater or leſſer convergency of the ſun's rays.

The learned Boerhaave, in his Theory of Chymiſtry, p. 245, Shaw's edition, obſerves, That thoſe white clouds which appear in ſummer time, are, as it were, ſo many mirrors, and occaſion exceſſive heat. Theſe cloudy mirrors are ſometimes round, ſometimes concave, polygonous, &c. When the face of heaven is covered with ſuch white clouds, the ſun ſhining among them, muſt, of neceſſity, produce a vehement heat, ſince many of his rays, which would otherwiſe, perhaps, never touch our earth, as hereby reflected to us. Thus, if the ſun be on one ſide, and the clouds on the oppoſite one, they will be perfect burning-glaſſes.

I have ſometimes (continues he) obſerved a kind of hollow clouds full of hail and ſnow, during the continuance of which the heat was extreme, ſince, by ſuch condenſation, they were enabled to reflect more ſtrongly. After this came a ſharp cold, and then the clouds diſcharged their hail in great quantity, to which ſucceeded a moderate warmth. Frozen concave clouds, therefore, by their great reflexions, produce a vigorous heat, and the ſame, when reſolved, exceſſive cold.

From which Dr. Hales obſerves as follow:

Hence we ſee, that blaſts may be occaſioned by the reflexions of the clouds, as well as by the above-mentioned refraction of denſe tranſparent vapours.

About the middle of july Hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be made of their ripeneſs, by their ſtrong ſcent, their hardneſs, and the browniſh colour of their ſeed.

When by theſe tokens they appear to be ripe, they muſt be picked with all the expedition poſſible; for if at this time a ſtorm of wind ſhould come, it would do them great damage, by breaking the branches, and bruiſing and diſcolouring the Hops; and it is very well known, that Hops, being picked green and bright, will ſell for a third part more than thoſe which are diſcoloured and brown.

The moſt convenient way of picking them is into a long ſquare frame of wood, called a bin, with a cloth hanging on tenter-hooks within it, to receive the Hops as they are picked.

The frame is compoſed of four pieces of wood joined together, ſupported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this ſerves to lay the poles upon which they are to be picked.

This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and ſix or eight perſons may work at it, three or four on each ſide.

It will be beſt to begin to pick the Hops on the eaſt

or north ſide of your ground, if you can do it conveniently; this will prevent the ſouth-weſt wind from breaking into the garden.

Having made choice of a plot of the ground containing eleven hills ſquare, place the bin upon the hill which is in the center, having five hills on each ſide; and when theſe hills are picked, remove the bin into another piece of ground of the ſame extent, and ſo proceed till the whole Hop-ground is finiſhed.

When the poles are drawn up to be picked, you muſt take great care not to cut the binds too near the hills, eſpecially when the Hops are green, becauſe it will make the ſap to flow exceſſively.

And if the poles do not come up without difficulty, they ſhould be raiſed by a piece of wood in the nature of a lever, having a forked piece of iron, with teeth on the inſide, faſtened within two feet of the end.

The Hops muſt be picked very clean, i. e. free from leaves and ſtalks, and, as there ſhall be occaſion, two or three times in a day the bin muſt be emptied into a Hop-bag made of coarſe linen cloth, and carried immediately to the oaſt, or kiln, in order to be dried; for if they ſhould be long in the bin, or bag, they will be apt to heat, and be diſcoloured.

If the weather be hot, there ſhould no more poles be drawn than can be picked in an hour, and they ſhould be gathered in fair weather, if it can be, and when the Hops are dry: this will ſave ſome expenſe in firing, and preſerve their colour better when they are dried.

The beſt method of drying hops is with charcoal on an oaſt or kiln, covered with hair-cloth, of the ſame form and faſhion that is uſed for drying malt. There is no need to give any particular directions for the making it, ſince every carpenter, or bricklayer, in thoſe countries where Hops grow, or malt is made, knows how to build them.

The kiln ought to be ſquare, and may be of ten, twelve, fourteen, or ſixteen feet over at the top, where the Hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln, and the beguels of the ſteddle where the fire is kept, viz. if the kiln be twelve feet ſquare on the top, it ought to be nine feet high from the fire, and the ſteddle ought to be ſix feet and a half ſquare, and ſo proportionable in other dimenſions.

The Hops muſt be ſpread even upon the oaſt a foot thick or more, if the depth of the curb will allow it, but care is to be taken not to overload the oaſt, if the Hops be green or wet.

The oaſt ought to be firſt warmed with a fire before the Hops are laid on, and then an even ſteady fire muſt be kept under them; it muſt not be too fierce at firſt, leſt it ſcorch the Hops: nor muſt it be ſuffered to ſink or ſlacken, but rather be increaſed till the Hops be near dried, leſt the moiſture, or ſweat, which the fire has raiſed, fall back, or diſcolour them. When they have lain about nine hours, they may be turned, and in two or three hours more they may be taken off the oaſt. It may be known when they are well dried by the brittleneſs of the ſtalks, and the eaſy falling off of the Hop leaves.

The Dutch and Flemings have another method of drying their Hops: they make a ſquare kiln, or room, about eight or ten feet wide, built of brick or ſtone, having a door at one ſide, and a fire place in the middle of the room, on the floor, about thirteen inches wide within, and thirteen inches high in length from the mouth of it, almoſt to the back part of the kiln, a paſſage being left juſt enough for a man to go round the end of it; this they call a horſe, ſuch as is commonly made in malt-kilns, the fire paſſing out at the holes at each ſide, and at the end of it.

The bed, or floor, on which the Hops lie to be dried, is placed about five feet high above; about that is a wall near four feet high, to keep the Hops from falling.

A window is made at one ſide of the upper bed, to ſhove off the dry Hops down into a room prepared to receive them. The beds are made of laths, or rails, ſawn very even, lying a quarter of an inch diſtant from one another, with a croſs beam in the middle to ſupport them; the laths are let in even with the top of the beam, and this keeps them even in the places; this they call an oaſt.

The Hops are laid on this bed by baſkets full, without any oaſt-cloth, beginning at one end, and ſo going on till all is covered, half a yard thick, without treading them; then they even them with a rake, that they may lie of equal thickneſs.

This being done, they kindle the fire below, either of wood or charcoal, but the latter is accounted the better fuel for Hops; this fire is kept as much as may be at an equal or conſtant heat, and only at the mouth of the furnace, for the air will ſufficiently diſperſe it.

They do not ſtir them till they are thoroughly dried, i. e. till the top is as fully dried as the bottom: but if they find any place not to be ſo dry as the reſt, (which may be known by reaching over them with a ſtick or wand, and touching them in ſeveral places,) they obſerve where they do not rattle, and where they do; and where they do not rattle, they abate them there, and diſpoſe of them where the places were rſt dry.

They know when they are thoroughly dry, by the brittleneſs of the inner ſtalk, if it be ſhort when it is rubbed; which when they find, they take out the fire, and ſhove out the Hops at the window that is made for that purpoſe, into the room made to receive them, with a coal-rake made with a board at the end of a pole, and then go in at a door below, and ſweep up the Hops and ſeeds that fall through, and put them to the other Hops; then they lay another bed of green Hops, and renew the fire, and proceed as before.

This method is diſapproved by ſome, becauſe (they ſay) the Hops lying ſo thick, and not being turned, the under part of them muſt needs dry before the upper; and the fire paſſing through the whole bed to dry the uppermoſt, muſt neceſſarily over-dry, and much prejudice the greateſt part of the Hops, both in ſtrength and weight, beſides the unneceſſary expenſe of firing, which muſt be long continued to dry thoroughly ſo many together.

Therefore ſome have improved on this method, and adviſed to make the kiln much as is before directed as to the Dutch way.

Firſt to make a bed of flat ledges about an inch thick, and two or three inches broad, ſawn, and laid acroſs one another the flat way, chequerwiſe, at about three or four inches diſtance one from the other, the edges being ſo entered one into the other, that the floor may be even and ſmooth; this bed may be made to reſt on two or three joiſts, ſet edgewiſe to ſupport it from ſinking.

This bed is to be covered with large double tin, ſoldered together at each joint, and the ledges muſt be ſo ordered, before they are laid, that the joints of the tin may always lie over the middle of the ledge, the bed being wholly covered over with tin: boards muſt be fitted about the edges of the kiln, to keep up the Hops, but one ſide muſt be made to remove, that the Hops may be ſhoved off as before.

On this bed, or floor of tin, the Hops may be turned without ſuch hazard or loſs, as upon the hair-cloth: and alſo it will require a leſs expenſe of fuel, and, beſides, any ſort of fuel will ſerve in this kiln, as well as charcoal, becauſe the ſmoke does not paſs through the Hops as it does the former ways, but then care is to be taken, that there be paſſages made for it at the ſeveral corners and ſides of the kiln.

It is found by experience, that the turning of Hops, though it be after the moſt eaſy and beſt manner, is not only an injury and waſte to the Hops, but alſo an expenſe of fuel and time, becauſe they require as much fuel, and as long a time, to dry a ſmall quantity by turning them, as a large one.

Now, this may be prevented, by having a cover (to be let down and raiſed at pleaſure) to the upper bed whereon the Hops lie.

This cover may alſo be tinned, by nailing ſingle tin plates over the face of it, ſo that when the Hops begin

to dry, and are ready to burn, i. e. when the greateſt part of their moiſture is evaporated, then the cover may be let down within a foot, or leſs, of the Hops (like a reverbatory) and will reflect the heat upon them, ſo that the top will ſoon be as dry as the lower-moſt, and every Hop be equally dried.

As ſoon as the Hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately, they will powder, but if they lie a while (and the longer they lie the better, provided they be covered cloſe with blankets to ſecure them from the air,) they may be bagged with more ſafety, as not being liable to be broken to powder in treading, and this will make them bear treading the better, and the harder they are trodden, the better they will keep.

The common method of bagging is as follows; they have a hole made in an upper floor, either round or ſquare, large enough to receive a Hop-bag (which conſiſts of four ells and a half of ell-wide cloth, and alſo contains ordinarily two hundred and a half of Hops) they tie a handful of Hops in each lower corner of the bag, to ſerve as handles to it, and they faſten the mouth of the hole, ſo placed that the hoop may reſt upon the edges of the hole.

Then he that is to tread the Hops down into the bag, treads the Hops on every ſide, another perſon continually putting them in as he treads them, till the bag is full, which being well filled and trodden, they unrip the faſtening of the bag to the hoops, and let it down, and cloſe up the mouth of the bag, tying up a handful of Hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, they will keep good ſeveral years; but care muſt be taken, that they be neither deſtroyed nor ſpoiled by the mice making their neſts in them.

The crop of Hops being thus beſtowed, you are to provide for another, firſt by taking care of the poles againſt another year, which are beſt to be laid up in a ſhed, having firſt ſtripped off the haulm from them; but if you have not that conveniency, ſet up three poles in the form of a triangle, or ſix poles (as you pleaſe) wide at the bottom, and having ſet them into the ground, with an iron pitcher, and bound them together at top, ſet the reſt of your poles about them; and being thus diſpoſed, none but thoſe on the outſide will be ſubject to the injuries of the weather, for all the inner poles will be kept dry, unleſs at the top; whereas, if they were on the ground, they would receive more damage in a fortnight, than by their ſtanding all the reſt of the year.

In the winter time provide your ſoil and manure for the Hop-ground againſt the following ſpring.

If the dung be r tten, mix it with two or three parts of common earth, and let it incorporate together till you have occaſion to uſe it in making your Hop-hills; but if it be new dung, then let it be mixed as before, till the ſpring come twelvemonths, for new dung is very injurious to Hops.

Dung of all ſorts was formerly more commonly made uſe of than now it is, eſpecially when rotted, and turned to mould, and they who have no other manure muſt uſe it; which, if they do, cows or hogs dung, or human ordure mixed with mud, may be a proper compoſt, becauſe Hops delight moſt in a manure that is cool and moiſt.

Some recommend chalk, or lime, as the beſt manure, except in cold lands, and in ſuch, pigeons dung will do beſt; a little of which laid to a hill, and ſo mixed, that it may not be too hot in a place, is of great advantage.

[*Hop Grounds in Kent.*

The principal part of the plantations of Eaſt Kent are on a good deep rich loamy ſurface, with a deep ſubſoil of loamy brick earth. There are however ſome good grounds, where the ſurface is very flinty, and ſome of a gravelly nature; but theſe are very inferior. The Hops growing about Canterbury and in Eaſt Kent are of a very fine rich quality, and if well managed, of a good colour. Middle Kent alſo, or the country round Maidſtone, the original ſpot where Hops were firſt planted, grows a great quantity, moſt of which is likewiſe of a very good quality; though ſome, being planted on land not fit for Hops, is coarſe.

When a piece of land is intended to be planted, plough the land as deep as poſſible early in october, and harrow it level; they mete or meaſure it each way with a four-rod chain, placing pieces of reed or ſtick at every tenth link, to mark the place of the hills, which makes one thouſand to an acre. Some few grounds are planted eight hundred, and ſome twelve hundred to an acre. Some are planted wider one way than the other, to admit ploughing between the hills; but this practice, although it has been tried many years, does not ſeem to increaſe, on account of the difficulty of digging along the rows where the plough cannot go; that part being much trodden with the horſes in ploughing digs ſo much the worſe, that an extraordinary expenſe is incurred, which in ſome meaſure defeats the economy of the plan. When the hills are marked out, holes are dug about the ſize of a gallon, which are filled with fine mould, and the nurſery plants placed in them.

Some put three plants, others two, and ſome only one good one to each hole. If cuttings be planted, the holes are dug in the ſpring, as ſoon as cutting-time commences; ſome fine mould is provided to fill up the holes, in which four or five cuttings are placed, each three or four inches in length: they are covered an inch deep with the fine mould, and preſſed down cloſe with the hand. Cuttings do not require any ſticks; but nurſery-plants muſt have ſticks or ſmall poles, ſix or ſeven feet high the firſt year: in both caſes the land is kept clean during the ſummer by horſe and hand hoeing; the next winter it is dug, and early in the ſpring the old binds are cut off ſmooth, about an inch below the ſurface; a little fine mould is then drawn over the crown of the hills. As ſoon as the young ſhoots appear, ſo that the hills may be ſeen, they are ſtuck with ſmall poles, from ſeven to ten feet long, in proportion to the length it is expected the bind will run; theſe poles are called ſeconds, and are generally bought in the woods at from five ſhillings to eight ſhillings the hundred, and three of them are placed to each hill As ſoon as the binds are about two feet in length, women are employed to tie them to the poles: and the land is kept clean during the ſummer with horſe and hand hoeing as before.

The proper time for gathering them is known by the Hop rubbing freely to pieces, and the ſeed beginning to turn brown. They are picked in baſkets containing five buſhels each, and are carried to the oaſt in bags, at noon and evening, for drying. Great care and ſkill are neceſſary in this branch of the buſineſs; the ſmalleſt neglect or ignorance in the management of the fires will ſpoil the Hops, and occaſion great loſs to the planter. When dried and ſufficiently cool to get a little tough, ſo as not to crumble to powder, they are put into bags or pockets; the former containing two hundred weight and a half, the latter a hundred and quarter: they are then trodden very cloſe, and weighed by the exciſeman.

The ſecond year after planting, full ſized poles from fifteen to twenty feet in length, according to the ſtrength of the land, coſting from ſixteen ſhillings to thirty-ſix ſhillings the hundred, are placed to the hills inſtead of the ſeconds, which are removed to younger grounds. Here great care is neceſſary not to overpole: for thus young grounds are often much weakened; and it is equally neceſſary not to overdung them, as that will make them mouldy. Fifty cart-loads of well-rotted farm-yard dung and mould, once in three years, are generally eſteemed ſufficient for an acre of land [¶].

In order to have Hops of a good quality: 1ſt. They ought to be ripe before they are gathered; and in getting ſo, they paſs from a green to a rich yellow colour. 2dly. They ought to grow on a ſoil, that inſtead of enlarging the ſize of the Hop, grows them

¶ Boys in Agric. Survey of Kent. 1 ſt 8vo edit.

full

full of farina (provincially condition). 3dly. They ought to be very much but ſlowly dried, and then packed for market in the thickeſt covering that can be found, to preſerve their ſtrength. The colour of Hops that hang till they are ripe can never be ſo beautiful as if they were gathered green, for they are generally bruiſed by the equinoctial winds. But the quality of their bitter is ſuperior in flavour, goes farther, and will never deceive in brewing; they will alſo keep good, when full dried, many years [s].

The implements neceſſary to a Hop-ground are,

1. An oaſt (to every plantation of four or five acres) about ſixteen feet ſquare, which built ſubſtantially with the requiſite ſtowage room, coſts from 150l. to 200l.

2. A ſet of picking baſkets, about twelve in number, which coſt about 5s. 6d. each. Alſo a good ſcale-beam with weights and ſcales, which together coſt about 5l.

3. A ſkim made with a frame like a wheelbarrow, which coſts about two guineas. This implement is very uſeful for tearing up weeds on ſummer-fallows.

4. A harrow to be drawn by one horſe, with a ſmall wheel in front, to go round at the ends of the plantation, and a pair of handles to be holden by the man who follows it, in order to keep it from bruiſing the binds. It coſts 1l. 15s.

5. An iron peeler to make holes in the land for the poles, coſting 6s. or 7s.: and a hop-dog to wrench them up, coſting 5s. [t].

Hop Grounds in Surry.

Mr. Miller mentions only three varieties of the Hop. In Surry they have what they call the Orchard Hop, which bears a long ſquare ſtrobile, and is perhaps the ſame with Mr. Miller's firſt. The ſtreaked Bind. Two or three varieties of White Bind. Smooth and rough Red Bind. The moſt eſteemed are the Streaked and the White Bind. The ſmooth Red is of little value; and as to the laſt, it is generally eradicated whenever it appears. The White Canterbury Bind is moſtly in uſe. The Golden Hop with a white Bind, which is probably the ſame with Mr. Miller's Oval Hop ripens later than the other, and therefore on that account may be uſeful to the planter. There is alſo the Cluſter Hop, produced from a White Bind, but having the Hops growing more in cluſters than the others. The ſtreaked Bind is a deſirable Hop for a part at leaſt of a plantation, being early, of a pleaſant flavour, and generally of a good ſize. As to the term Garlick, it is not appropriate to any one variety; for they will all acquire that ſort of ſmell from diſtemper.

As to the ſoil, there will be no doubt of Hops thriving when there is good marl or chalk, or even a moiſt rock at bottom, with a ſurface of tolerably deep mould frequently manured.

In the preparation for planting, and the manner of it, the practice is very various. The ground is generally ploughed and harrowed well the winter before it is intended to be planted; but it does no ſeem neceſſary: for by the time the workmen have gone over it, firſt to ſet out the hills, and then to dig the holes and plant the Hops, the ground becomes ſo trodden as to be little the better for ploughing. A better method ſeems to be to prepare the ground well the ſummer before, and ſow it with Turneps, by which means it is thoroughly clean; and early in winter, (or if in autumn the better) either to pull up the Turneps or feed them off with ſheep, as occaſion may require; and ſo let it remain till the ſpring; and then plant the Hops, and immediately dig the ground. Sow Turneps again the enſuing ſummer, and as theſe muſt be hoed twice, the young Hops are cleaned at the ſame time. When they are ſpent, care muſt be taken, if they are fed off on the ground, to do it in dry weather. Thus the land is dreſſed by the ſheep, and will not require ſo much dung at firſt. Beans alſo or Potatoes may be planted the firſt year between the hills; and by either mode ſomething is made of the ground, for the Hops yield nothing that year, and indeed very little for profit the ſecond.

In Surry they have not the practice of planting Cherry or Apple trees as in Kent. About Alton they generally plant their Hops ſix feet ſquare; but about Farnham they plant much nearer: the ſuperiority of their ſoil enables them to do this with ſucceſs; but in blighting years they ſuffer more than the Alton planters; the circulation of air being much obſtructed by the cloſeneſs of the hills.

October is the moſt proper ſeaſon for planting with cuttings of the laſt year, or nurſery plants, as they are uſually called; and march, if you plant with cuttings of the ſame ſpring, that being the time of cutting Hops in general.

With regard to manuring the Hop-ground, every other year is often enough, and then about twenty dung-cart loads on an acre. It is the more frequent practice to lay the dung on the crown of the hill, that the rains in winter may waſh it down to the roots: but ſome ſpread the dung over the ground in autumn, and ſeldom dig it in before february. Part of it is brought to the hills in the courſe of hilling the Hops in ſummer; and part remains in the intervals for the nouriſhment of the fibres.

In cutting the Hops, a neceſſary caution ſhould be obſerved reſpecting ſuch as are young, not to uſe the knife too freely the firſt year. At this age a ſufficient number of joints ſhould be left below the knife; and if the plants are weak, it may be as well only to trim off the dead bind of the laſt year.

As to the length and ſize of the poles experience muſt direct the planter: but it is undoubtedly better to underpole, than to uſe ſuch poles as the Hop cannot over-climb.

After tyeing follows hoeing and the firſt hilling; then the ſecond hoeing and hilling, which finiſhes the buſineſs of cultivation; and ought to be done before the fibres get out much in the intervals, leſt theſe be diſturbed, and of courſe the growth of the Hops be checked. A very uſeful implement in this buſineſs is a triangular harrow drawn by one horſe, ſo conſtructed that the tines may break up all the ground. It not only roots up the weeds, but by looſening the ſurface expedites the workman's labour, and keeps the ground from cracking, eſpecially after the laſt hilling, when it is ſcraped over ſmoothly by the hoe in drawing up the hills. A man with a boy to lead the horſe will go over three acres in a day.

The Hop-grower has many enemies to dread. A fly ſimilar to that which is ſo injurious to Turneps attacks them on their firſt appearance in the ſpring, and ſometimes deſtroys the firſt ſhoots entirely: it is a very ſmall animal, and on going near to touch it, retreats into the ground with the nimbleneſs of a bed-flea. A handful of aſhes ſcattered over every hill is very ſerviceable in driving them away. The next enemy is the fly mentioned by Mr. Miller, by which he means the long-winged fly, as it is here called. The appearance of theſe animals is dreaded by the planter as a peſtilence; they are the forerunners of lice, and in the end generally prove fatal to the crop. It is an opinion with many that rain will waſh them off, but in this they are undoubtedly miſtaken, for they moſtly ſhelter themſelves on the under ſide of the leaf, where no rain can touch them. Lightning ſeems to be their greateſt enemy. Honey-dews are likewiſe very injurious to Hops; cauſing their leaves to turn black, ſhrink at at length fall off. They are ſometimes ſo affected with this diſtemper and the lice united, as to periſh entirely, and require to be planted anew for many hills together. Another calamity to which Hops are liable is the Red Blight. This ſeldom attacks them until the time of their coming to maturity; cauſing the Hops to turn reddiſh, or rather of deep yellow, and the leaves frequently to grow pale and ſickly. When this is the caſe, they acquire a garlick-like ſmell, and ought to be picked with the greateſt expedition. This diſorder being incident to particular lands, thoſe eſpecially of a light and weak nature, it appears rather to be a natural decay than a blight.

Experience will beſt teach the planter when his Hops

[s] Ibid. app. 188. [t] Ibid. p. 49. & 120.

are fit for picking. It is however the more prudent way to begin too ſoon than too late, as the high winds which prevail towards the equinox many times produce more injury to the planter, than he would ſuſtain by beginning a day or two before his Hops were thoroughly ripe. It is the prevailing opinion that the laſt-picked Hops will weigh heavier when dried than the firſt. This however is an error; for in the year 1788 I began picking Hops on the 18th of auguſt, being induced by the extreme ſcarcity of Hops in London, and knowing that I ſhould get a great price at that market. I was however at the ſame time perſuaded that they are ripe enough not to loſe their colour on the kiln. By the 28th of auguſt I was enabled to ſend near a ton to London, where I got ſome pounds for the hundred weight more than I did afterwards at Weyhill. Having cleared my kiln, and bagged off all that I had gathered, I had a fair opportunity of judging of the different weights of the firſt and laſt pickings, and on compariſon I found that the advantage lay on the ſide of the firſt. A buſhel of green Hops, in a favourable year, when they are well conditioned will yield about a pound and half in weight when dry *.

Hop Grounds in Worceſterſhire.

The different ſorts of Hop cultivated here, are the red, the green, and the white. A various cultivation, the real ſource probably of theſe firſt diſtinctions, has introduced a variety of each, though differing little more than in name and degree, of the ſame colour, ſhape, and ſize. There are two, however, in more particular eſteem, both with the planter and merchant; the Golding Vine, brought from the neighbourhood of Canterbury, and the Mathan White, the name of which denotes it to be a native of this plantation, and of the pariſh of that name. The moſt hardy, that which will flouriſh with the leaſt attention, and is leaſt liable to ſuffer from the ſeaſons, is the red; perhaps the original ſtock. The next is the green; which is alſo the moſt productive. The tendereſt, though at the ſame time the more valuable, is the white. The plantations of this county are principally to the weſt of the Severn, increaſing as they approach the banks of the Teame, and the confines of Herefordſhire. The ſituations preferred, are a gentle deſcent, with a ſouth, ſouth-weſt, or weſtern expoſure, ſcreened at a diſtance to the north and eaſt by high ground, or plantations of timber; but not ſo as to prevent a free ventilation: the ſoil, a deep loamy land, or ſtrong clay, after it has been thoroughly limed and manured: but above all a boggy ſoil, when completely drained, and duly meliorated, is ſaid to produce the beſt Hops.

When meadow or paſture land is broke up for this purpoſe, it is either dug, or the ſward, being firſt pared thinly off by the paring plough, it is buried by the furrow-plough, working full ten inches deep. Old tillage, when converted into Hop-grounds, requires to be very completely cleared of woods; to be thoroughly manured, and to have the ridges, provincially lands, entirely levelled. The different manners in which they are worked, are, the tump, and the ploughed grounds; the former by hand, and the latter by the plough: thoſe are laid out in the quincunx form, each tump (or hill) being at the diſtance of from five to ſeven feet from the centre of each other. On theſe, the diſtance between the ſtocks, is from three to four feet; that between the rows, from ſeven to nine; the greater or leſs ſpace being always allowed, as the land is either richer or poorer. In the ploughed, if the circumſtances of the ground will admit of it, the rows run moſtly north and ſouth, with a view to admit the ſun more generally when it has moſt force; but ſhould it be long and narrow, its greateſt length extending eaſt and weſt, that direction is preferred: there are thoſe who give it the preference when not influenced by any accidental circumſtances, as receiving the morning ſun, by which the chill of the night is ſooneſt diſſipated. The ſets are procured from the ſhoots, or roots of the ſtocks, at the annual time of dreſſing, the latter end of march, or beginning of april. They muſt have two joints each, the roots ſtriking from that in the ground, and the vine ſhooting from that above. Four are planted to a ſtock, at the diſtance of about four or ſix inches from each other, all inclining or pointing, ſo as to meet together in the centre.

There are two methods obſerved in planting young Hop-grounds; the firſt and more general is, to plant the ſets on the ſituation in which they are to remain, immediately after they are parted from the old ſtocks. In the other, the ſets are planted in nurſeries, in rows about three inches aſunder, with about five or ſix inch between the rows; here they grow till the month of october, when they are tranſplanted into the Hop-ground. Under this latter management, if the roots are good, one will be ſufficient for a ſtock. In removing them, great care muſt be taken to make the opening to receive them ſo large, as not to confine the roots; when planted from the ſtocks, a hole made with a peg, to place them in, is all that is required. The nurſery has certainly great advantage; beſides the ſaving of a conſiderable expenſe, where the ſets are to be purchaſed, the land may be worked through the ſummer, to prepare it for the plantation. During the firſt year, the grounds are ploughed, or hoed, provincially kerſed, three times. They produce no Hops; but a good crop of Peaſe, Beans, Cabbage, or Turneps, is obtained between the rows. The ſecond year they are poled, and yield half a crop: the third year, they are in perfection. When they have reached this ſtate, the management is uniformly as follows:—They are gone over, moſtly four times, with the plough or kerſ, beginning about march. The firſt buſineſs is to throw down the tumps, and rows of the former year, and to work in the manure, previouſly brought on in the winter. This conſiſts of freſh earth, rotten dung, or a compoſt of dung, earth, and lime, judiciouſly proportioned, according to the nature of the ſoil; each acre receiving not leſs than ſixty cart loads, for a good dreſſing—it is repeated, according as the nature of the land renders it neceſſary. The ſtocks are now pruned, the remains of the old vines, and ſuperfluous ſhoots, are removed with the hop-knife. The ſecond moulds up the tumps and rows; the ſucceeding ones complete moulding up the plants, and deſtroy the weeds. The tumps are formed round, flat at top, and about twenty inches diameter, and ſomewhat broader at their bottom. The ploughed lands are thrown up much in the ſame manner as for Potatoes, or Beans, only higher, and with more ſoil. The ſhoots begin to appear in april, and the poles are pitched the latter end of the ſame month, or beginning of may. Theſe are ſet two or three to a ſtock, at a foot diſtance from each other, with great regularity and exactneſs, and inclining a little outwards, over the alleys. Some attention is neceſſary, in this part of the buſineſs, not to overpole the plants, either in number, or length of the poles, as it weakens them; and by drawing the vine out to too great a length, renders them leſs productive. About the cloſe of this month, and beginning of june, women are employed to direct the vine to the poles, and tie them with dried ruſhes. This is continued till they are out of reach. The only care now remaining is, to keep under weeds, and to go over the plantations occaſionally, to replace any vines that may ſtray, and repair any damage the plants or poles may have received from the weather. When they have reached their full growth, which is, in ſome meaſure, regulated by the number and length of the poles, the ſide ſhoots put out. The method of topping the vines, to promote the lateral ſhoots, ſaid to be practiſed in other plantations, is never uſed in this.

About the ſecond week in ſeptember they ripen, when the hop pulling begins. In a plentiful year, it continues ſix weeks, more or leſs, according to the crop. The cribs are now placed, beginning on that part which lies moſt expoſed to the ſun, as being ſooneſt ripe; one, two, or more, as the proprietor's plantation is large or ſmall, and he has the convenience of kilns to dry them. Each crib has eight or ten pickers, women and children; they pick, if there is a tolerable crop, and they are any ways induſtrious, from ſix to eight buſhels each per diem, which is about a ſackful

* Obſervations communicated by Mr. Prowting of Chawton.

sackful (the sack in which they are carried green to the kiln); eight of these sacks, when dried, make about one hundred weight; but in some seasons, though no ways negligent, they will fall short of one half of this quantity. The pickers come from the neighbouring counties; but the far greatest number out of Wales; some from thirty and forty miles distant. From the cribs, the Hops are conveyed to the kilns, four or five of the sacks alluded to before, at a time, on a horse, and are dried as soon as possible: they damage considerably, if suffered to lie long together before they are put on the kilns. They will heat in six or eight hours, and lose colour; to avoid which, the kilns are kept constantly employed day and night. The time the Hops take in drying, is from eight to twelve hours, according as they are ripe and dry. Great attention, and considerable judgment, are necessary in this part of the business, the whole of the year's expenses and labour, and at times property to some amount, being at stake on a single kiln—it is usually entrusted to those who have been long used to the practice. The general principle on which they proceed, is to begin with a very gentle fire, till warmed through; the heat is then gradually increased, and continued till the core (fruit stalk) is quite sunk and dry. They are then removed, and thrown together in a heap, in a corner of a large room, appropriated to this purpose, and frequently turned from one side to the other, in order to cool them completely before they are bagged.

The method of bagging is as follows:—A strong hoop is made fast about the mouth of the sack, which is then let down through a circular opening in the floor, made for this purpose; a few are first put in, when the man who is principal in this part of the business, gets in, and by constant treading, presses them down as close as he can. A second person is employed in breaking them (that is, tearing the flowers, &c. from the fruit stalk) and throwing them into the bag as they are wanted: thus they proceed till it is full, when the mouth is loosened from the hoop, and closed, leaving at each corner of the sack a space for the hand, for the better convenience of those who are employed in carrying them.

In the ground, nothing more is done, but stripping and piling the poles; these are always set up in them, about three hundred in a pile, sloping and propping each other, the better to withstand the wind. Different opinions are entertained respecting the superiority of the tump and plough management; the former has certainly the advantage in many particulars; and is said to be cheaper and more productive: but as it is impossible, from the present extent of the plantation, that any considerable proportion can be worked in this manner, from want of hands, the enquiry cannot be of much consequence. The expenses of these plantations may be calculated from the following statement:—As they always occupy the most valuable tract on the farm, the rent cannot be set down lower than thirty-one shillings per acre, in some instances it is much higher. The acre is not to be estimated as statute measure, but after the rate of one thousand stocks to the acre, which is in general one-fifth less. The expense of manure is very heavy, as they produce none, except the ashes from the burning of the vines and leaves; so that were justice done to the rest of the land, the greater part ought to be procured from home. The price of dung (provincially muck) in general, is about six shillings per waggon-load, or three shillings per ton; (if from stables, in which horses are fed plentifully with corn, the price runs higher in proportion) and is frequently to be fetched eight or ten miles.

The Hop-grounds are worked sometimes through the several seasons, as they are termed, at a fixed price, which is from fifteen shillings to twenty shillings per acre, according to the different quality of the soil. The seasons are four, and thus divided;—throwing down and cutting, spreading and pitching poles, kerfing and tumping, stripping and piling poles: otherwise the workman receives his usual pay of one shilling per day, with drink; or some parts are taken by the acre, as pitching poles three shillings, stripping and piling two shillings and six-pence to three shillings and six-pence. The women employed to tie the vine receive six-pence per day, with two quarts of drink; or they take them by the year, at three shillings or three shillings and six-pence per acre. The Hop pullers receive from six-pence to eight-pence per day, with a pint of thickened milk, or something similar, for breakfast every morning; two quarts of drink per day, and two dinners every week. The pole-man, he who brings and removes the poles, has all his meals, drink, and from four shillings to six shillings per week. The coal (pit-coal charked) with which they are dried, is also an expence of considerable consequence, it is chiefly procured at Pinfax, in this county, at a distance of several miles from some of the plantations, where it costs two-pence half-penny or three-pence per bushel; twenty-eight bushels are a ton, and it takes two tons of coal to dry one of Hops. The drier is paid from twelve shillings to twenty-one shillings per week, varying according to the number of kilns he has to attend: he has also his meals and drink. He who has the management of the bagging, is paid four-pence per hundred weight, exclusive of his assistant. There are different articles used for bagging: the Lubecks, and a sort of cloth manufactured at Dudley, in this county, are the most in use, and chiefly the latter. The price varies according to the demand. The Lubecks are dearest; they cost, in general, from twenty-eight shillings to thirty-four shillings per piece, and are thirty-six yards long, and about thirty-one inches wide. The Dudleys cost from twenty-two shillings to thirty-two shillings, and are of the same dimensions, each piece making eight sacks, four yards and three quarters long.

Most of the estates which grow many Hops, have plantations in which the poles are raised. Ash and barked oak are preferred; but willow, poplar, and alder are also used. Where the estate does not produce a sufficiency, they are bought at the woods and coppices in the neighbourhood, at from five shillings to fifteen shillings per hundred: their length is from eight to eighteen, or twenty feet, proportioned to the goodness of the lands; they last, with care, seven or eight years. The sets, when bought, cost from six-pence to two shillings and six-pence per hundred. The last expence is the duty, which is one penny per pound, and fifteen shillings per cwt. on the produce. The average of the expenses in general, is thus estimated; that of workmanship, from twenty-five shillings to thirty shillings per acre; those of picking, drying, charcoal, sack, and duty, thirty shillings per hundred weight. The implements used throughout this plantation are, the plough, the kerf, the spade, iron-crow, and the hop-knife. The plough is the common one of the district; the kerf is a large hoe, with a plate about nine inches broad, and thirteen deep; the spade needs no particular description; the crow is an iron bar, about four feet and a half long, generally square at top, with a large point, in the octagon form, used to make the hole in the ground in pitching the poles: the hop-knife resembles in make the sickle, an old one being often converted to this purpose, by grinding off its saw-edge, and giving it a sharp one in its stead; when made with new metal, it is something smaller. The crib into which the Hops are picked, is an open frame made of wood, standing about four feet high, four feet broad, and nine long. To the upper edge of this, is fastened the crib-cloth, which is nine yards double, made with the same stuff with the bags, but coarser and cheaper. The sacks in which they are conveyed to the kiln, are the same. The kiln will be afterwards described.

When the Hop-grounds are come to perfection, it is the general practice to exclude every other growth, and trust to them alone, for a return of the great expence at which they are cultivated. Under this management, those which have been uniformly attended to in their prime, and not weakened by over poling, will continue to produce plentifully from twenty to thirty years, and in some instances much longer, care being taken to replace the stocks that accidentally decay. On the other hand, fresh grounds are generally allowed to produce the finest Hops, and in greatest

abundance. *A queſtion of ſome difficulty ariſes*, at what time it will anſwer beſt to give up the old, and plant new grounds, and muſt at laſt be determined by the peculiar circumſtances of each plantation. But the error of continuing the old, as they often are, years after they have paſſed their prime, is ſelf-evident. The firſt expenſe of the new, may weigh with the occupier who holds his farm by the year, or for a ſhort term; but this is not the caſe with many of the principal planters. The ſame obſervation holds good with reſpect to the fruit plantations: theſe are often ſuffered to encumber the grounds, when there is ſcarce a hope left, that they may produce a crop any wiſe adequate to the expenſe of continuing them. This has given riſe to the following practice, and were it univerſally adopted, it would probably prove advantageous to the planters in general:—The young Hop-grounds are planted at proper diſtances with fruit-trees; theſe, from the frequent turning the ſoil and manure, are found to thrive better, and of courſe come to perfection ſooner, by this than any other managment followed in this county. The conſtant attention to the fences neceſſary for the Hops, is of the greateſt ſervice to the trees, by protecting them from their greateſt bane, the teeth and rubbing of cattle of every deſcription. For years, there can be no doubt but the advantage to the trees more than compenſates any loſs the Hops ſuſtain, conſiderably. Later, it is true, the trees prove prejudicial, by the ſpreading of their roots, and by their branches intercepting the light and heat of the ſun; preventing alſo a free circulation of air. This, however, will not happen in any conſiderable degree, till they are fifteen or twenty years growth, the time when the Hops, under this management, may be expected to decline, and it will be neceſſary to apply the land to the purpoſes of which it is moſt capable as an orchard. In this method, there would always be a conſtant ſucceſſion of young vigorous plantations of both produce. Thoſe years in which the Hops fail, ſome return for the great labour and expenſe they are attended with, might be looked for from the fruit; a larger proportion of the land would ſhare in turn that extraordinary attention which is now confined to thoſe parts on which the Hops are grown. The crops of theſe would probably never riſe ſo high as they occaſionally do now; but it muſt be remembered, theſe are not thoſe which pay the planters beſt, as all the expenſes on the produce are the ſame, on a given weight, whatever price it bears. Moreover, the average produce of the plantations is now ſaid to exceed the conſumption: in the great years, ſuch as the preſent, ſo much ſo, as to reduce the price ſo low as ſcarcely to repay the planter; they are, nevertheleſs, increaſing: thoſe of this county, within the laſt three years, have added one hundred and fifty acres to their former growth, and this, notwithſtanding their appears but little proſpect of any new markets for them being found: a very ſerious conſideration, and highly deſerving the utmoſt attention of the planters. If this ſtatement proves true, the following practical inference may be with certainty drawn from it—that it will be adviſeable to forego ſome of thoſe points which are particularly calculated to aſſiſt the crops of Hops alone, in favour of a produce, the value and conſumption of which are conſtantly increaſing.

The circumſtance of thoſe Hops which are moſt in requeſt, ripening all at nearly one time, is a conſiderable inconvenience both to the owner, and holder of the eſtate: as they damage ſo ſoon, whether left on the wires when ripe, or gathered, if not dried immediately, it is neceſſary to have buildings, and a number of kilns in proportion to the ſize of the plantations, and more hands during the ſeaſon, than would be otherwiſe wanting. Could thoſe ſorts which ripen earlier or later, be improved, or any others introduced, that do ſo, it would be a conſiderable acquiſition. The parts neceſſary to perfect the ſeeds, are found on different plants; and as the greateſt ſtreſs is laid on theſe, it may be proper to notice, that the practice of removing the barren ſtocks, may be carried too far: it is an enquiry well worth attending to, whether this may not be the cauſe, in ſome inſtances, of the early decay on ſome grounds.

The following obſervations of Dr. Withering (Bot. arrang.) on the honey-dew, deſerve to be introduced to the notice of the planters.—"If the hop-yards were "covered with ſtones, the plants would be leſs liable "to ſuffer from the honey-dew, or from the otter "moth; for the honey-dew is the excrement of a "ſpecies of louſe (aphis); but theſe inſects ſeldom "increaſe ſo as to endanger the plant, unleſs it is in a "weak condition; and the larvæ of the otter moth at "the roots, firſt occaſion the plant to be ſickly. Now, "when the Hop grows wild in ſtony places, and fiſ-"ſures of rocks, where the moth cannot penetrate to "depoſit its eggs, the Hop is never known to ſuffer "from the honey-dew."

Under this view of the diſeaſe, might not the practice of ſmoaking the fruit plantations, on the firſt alarm of a blight uſed in ſome fruit countries, be applied here to thoſe of Hops? The other injuries to which they are liable, ſtill remain without a remedy. A free circulation of the air through them, and complete draining of the land, are the only dependence. The uſe of the kerf is attended with one diſadvantage, and which, when employed almoſt ſolely to deſtroy weeds, is of conſequence: the perſon working with it, in ſome meaſure, defeats the intention of his labour, as he is continually treading down the ſoil again, he has thus looſened; and thus, in ſome degree, re-ſets the weed he had but a little before turned up; but the greater diſpatch made with it, more than can be done with the ſpade, will probably continue it that preference in which it is held.

The conſtruction of the kiln is as follows—The brick-work riſes perpendicular from the ground, to a height ſufficient to admit of about two or three feet below the bars, or grate, on which the fire is made, and about ſix or ſeven above it. The dimenſions at the baſe vary, according to the ſize required for the grate, and to give the brick-work ſufficient ſtrength to ſupport the ſuperſtructure. The height of this is determined by that of the building, when it is not erected new for the purpoſe. At the top of the perpendicular brick-work, iron bars are fixed at right angles; on them are laid tiles, or large flat ſtones, where they can be procured; theſe are covered on the upper ſide with a coat of mortar. The name given to this part of the kiln, the ſpark ſtone, ſufficiently denotes its uſe; it is placed in the centre, and of ſuch ſize, as leaves room around it to admit the heat above, at the ſame time that it prevents the ſparks from the fire being carried there. From this part, the brick-work becomes wider, overhanging gradually for about four feet, in a funnel ſhape, when it again riſes perpendicular about two feet: here joiſts are worked in, at ſmall diſtances from each other, and on theſe, laths are nailed, forming the floor. The brick-work is continued a foot higher, forming a breaſt work round the top; on the floor, and round this breaſt-work, the hair-cloth is ſpread, in which the Hops are contained[1].

Hop-grounds in Eſſex.

The culture of Hops at Hedingham is perhaps as good as in any part of England; the quality of thoſe at Farnham are ſuperior. There are fifty-five or fifty-ſix acres here contiguous, remarkable for yielding an almoſt certain crop. The ſoil is a moory marſh, improved into a rich loam on the ſurface. They are perſuaded here that Hops ſucceed better in very large plantations than in ſmall ones; and obſerve that the outſides of the contiguous acres do not anſwer equally with the more central diviſions. If a man therefore increaſes his Hop-ground, it ſhould not be in diſtinct plantations, but united to what he had before[2]. In Eſſex they are too apt to uſe long poles, even ſuch as are two rods in length, and thirteen inches round at bottom, coſting 3l. a hundred[3].

In making a plantation they fallow the land a year,

[1] Pomeroy, in ſurvey of Worceſterſhire, p. 46 to 57.
[2] Young's Ann. 18. 436. [3] Ibid. 2. 34.

plough

ploughing three or four times. They plant in november, three sets to a hill, and a thousand hills to an acre. They put on no manure, if the land be good. They dig the ground over as soon as planted, on account of its being trodden.

In the second year nothing is done but keeping the ground clean, by skimming and harrowing; after michaelmas they put on sixty loads of compost to an acre. Glovers and taylors shreds are a good dressing.

In the third year in february they cut down to the crown of the plant or the black rind. At the end of march they pole the ground, three poles to a hill. The best poles are chestnut, ash, oak, sallow, maple, all fourteen years growth, if from a wood, or eleven from a plantation. After poling, they dig round the plants.

In drying, much attention is necessary, to vary it according to ripeness and dryness.

The best soil is a strong loam; clay and a light black mould are both bad.

The flea attacks the Hop as soon as it is out of the ground. Chalky land is much subject to it, and warm dry weather occasions it. The best remedy is to dung highly, in order that the plants may grow out of danger, which is at two feet high. They apply nothing to stop it, but a heavy shower of rain does it.

In june and july the green-fly blows them, when lice come, which do not appear to eat, but poison the leaf; they are worst in thick, cloudy, hot, moist weather; when honey-dews come also upon them. (The flies and lice are all Aphides, some of which have wings, others not; and the honey-dew is their excrement.)

Hops when ripening get mouldy at the tip, where the Hop joins the stalk. This is a sort of rottenness, and moist weather is bad for it: a close low plantation, too much sheltered, or near trees, will be mouldy, when an open free exposure escapes [7].

Hop-grounds in Suffolk.

The soil they plant on about Stowmarket, is a black loose moor, on a gravelly bottom, very wet and boggy, lying on a dead level with the little river that runs by the town; the more boggy and loose it is the better the Hops thrive, especially if the gravel be within three feet; the neighbouring grounds rise in such a manner as to shelter them very well. In preparing for Hops they form beds sixteen feet wide, by digging trenches about three feet wide, and two feet or two feet and a half deep, the earth that comes out being spread upon the beds, and the whole dug and levelled. Upon this in march they form holes six feet asunder every way, twelve inches diameter, and a spit deep, consequently there are three rows on each bed. Into each hole they put half a peck of very rotten dung, or rich compost, scatter earth upon it, and plant seven sets in each, drawing earth enough to them afterwards to form something of a hillock. Some in the first years sow Kidney Beans, or common Beans, or plant Cabbages; but others do not reckon this a good way. In two or three weeks, according to the season, they will be fit to pole with old short poles, to which they tie all the shoots or vines, and then keep the land clean by hoeing and raking; and at midsummer they hill them. The produce the first year is from three to one hundred weight of Hops on an acre.

Manure is not always given regularly, but amounts on an average to ten loads a year. They keep it till it would run through a sieve, which they prefer to a more putrid state.

Three poles are put to each hill. They are generally of ash, and the length they prefer is twenty-four feet. When a Hop rises much above a pole, they set another to take the shoot, to prevent its falling, impeding the circulation of air, and entangling with the poles of other hills.

A Hop garden will last almost for ever, by renewing the hills that fail, to the amount of about a score annually; but it is reckoned better to grub up and new plant in twenty or twenty-five years.

[7] Young's Ann. 18. 451.

The only distempers to which they are subject are the fly and honey-dew; they know the blast and the red worm, but they are rare; the latter chiefly on dry land. They think lightning favourable, by killing flies and lice [8].

General observations.

Hops are occasionally very profitable, but they are very uncertain in their produce, and are sure to be very expensive. To lessen the expense of poling, and the trouble of picking, it has been suggested that planting Hops in form of an espalier might probably answer; for it is observed that when a pole falls, and another is obliged to be fixed in a lateral position, the Hops always bear more by being thus trained horizontally; and Hops in an espalier might be picked as forward as the planter chose without cutting the vines [9].

If Hops also were only planted in such soils and situations as are well adapted to them, there would be a much greater probability of an efficient crop; and thus though the expense would not be diminished, the average profit would be increased.

The quantity of Hops produced on different soils in different years, varies from almost nothing, or perhaps two hundred weight to twenty and even twenty-four hundred weight on an acre; but the average produce on middling soils may be estimated at six, and on such as are better, at seven or eight hundred weight, some speak of nine, and a good soil, with a run of favourable years, may yield such a produce, or even more, but it ought not to be looked upon as general. The expense on an acre of Hops may be estimated at about 30l., including rent, taxes, &c. Taking then 7 C. to be the average produce, the planters must evidently be losers when they sell for four guineas. Or taking 30l. as a standard, the price of Hops should vary according to the following table.

Quantity.	Price.
2 C. on an acre,	15 l. the hundred weight.
3	10
4	7 10 s.
5	6
6	5
7	4 5 8½
8	3 15
9	3 6 8
10	3
11	2 14 6½
12	2 10
13	2 6 12½
14	2 2 10½
15	2
16	1 17 6
17	1 15 3½
18	1 13 4
19	1 11 7
20	1 10 0

Neglecting small fractions in two or three instances. Whatever the grower gains more than this is profit. The average price of Hops has been estimated in different places, and by several persons in the same places at three guineas, at 4l. at 4l. 10s., at 5l. and at 6l. 2s. or 3s. The average of the prices given in the table above is 3l. 17s. 11½d. nearly.

Savings might certainly be made in poles; in cultivating only on proper soils, as hinted above, where a less quantity of manure is wanted than on such as are congenial to this crop; or in the vicinity of great towns where manure may be had in great plenty; by an attention to the quality, operation and effect of different manures, with the best time of laying them on; by uniting the business of malster to that of hop-grower, by which means the malt-office may save the expense of building an oast, or kiln for drying them; and by other attentions of which the hop-planter ought to be the best judge. The tythe of Hops should be regulated; where the expense to the cultivator is so prodigious, nothing can be more reasonable.

[8] Ibid. 2. 162. [9] Ibid. 2. 54. & 77.

In

In Suffex, brimſtone is uſed in drying Hops: it is thought there to be a well-grounded opinion, that this is a very proper fuel, ſince the inflammable principle with which it abounds, by ſuddenly paſſing through the Hops, quickly diſſipates the moiſture, by which means the Hops are brought off with a better colour, and with much leſs fuel than in the ordinary way [b].

I do not know whether this is practiſed in the other countries where Hops are grown, but I rather ſuſpect that brimſtone is uſed more to gratify the eye than for any good purpoſe. Almoſt every thing, in manufactures as in common life, is ſacrificed to appearance.

Though in very favourable ſoils, Hops may be continued on the ſame ſpot at pleaſure, yet it is generally adviſeable to break up the hop-yard entirely in twenty or thirty years; and then the ground is in high order for almoſt any crops for ſome years after, particularly for Potatoes, of which an immenſe burden may be produced from ſuch ground.]

DESCRIPTION, *&c.*

This grows naturally in the Spaniſh Weſt-Indies, from whence is has been introduced into the Britiſh colonies of America, where ſome of the plants are preſerved by way of curioſity. It riſes with a ſoft woody ſtem to the height of twenty-four feet, dividing into many branches, which abound with a milky juice, and have ſcars on their bark, where the leaves have fallen off. The branches are garniſhed with heart-ſhaped leaves; thoſe which are biggeſt are eleven inches long, and nine inches broad in the middle, indented on their edges, having a prominent midrib, with ſeveral tranſverſe veins from that to the ſides, which are alternate; theſe ſtand upon long ſlender foot-ſtalks. The male flowers come out from between the leaves, upon peduncles which are three inches long; they are formed into a cloſe ſpike, or katkin, forming a column, lying over each other like the ſcales of fiſh.

It is ſimple, and either terminating or axillary. The female flowers are ſolitary, and very near the ament. The leaves are alternate, and accompanied by caducous ſtipules; the petiole is glandular above; the younger leaves are involuted [a].

Browne makes this tree of the ſame genus with the Mangeneel (Manchineel or Hippomane). The branches are divided alike in both; and the leaves, which ſtand in the ſame manner, reflecting a little backwards from the direction of the foot-ſtalks, are diſpoſed pretty thick at the extremities of the branches, and have one gland only on each foot-ſtalk; whereas in the Manchineel there are two. This is full of a thick tranſparent juice, that of milk, both acrid; and the flowers, notwithſtanding they differ in ſome degree, agree in the formation of the ſtyle and ſtigma, as well as in the diſpoſition of the anthers; though the number of theſe be not the ſame in both. In this the fruit is regularly divided into cells: in that the nut or ſhell is harder, and the diviſions not ſo regular; yet they are longitudinal, adjoining, in a number proportioned to the diviſions of the ſtigma, and generally both regular and many in the younger germs, but ſome abortive as the fruit increaſes.

The fruit is very curious in its ſtructure; and the tree, when it grows well, is very ſpreading and ſhady [b]. It riſes to the height of thirty-five or forty feet, and ſometimes caſts a ſhade of ſixty feet diameter. But from the quickneſs of its vegetation, its parts are of ſo looſe a texture, that a loud clap of thunder, or a ſudden guſt of wind, frequently cauſes the largeſt boughs to ſnap aſunder. Nor is its trunk of any uſe, except for fire-wood [c].

Linneus ſays that the wood is fit for joiſts and ſpars and that the juice, when it gets into the eyes, brings on blindneſs after the eighth day [d].

The ſeeds, according to Hernandez, when roaſted, purge both upwards and downwards. Browne taſted one of them, and it appeared at firſt to be both mild and pleaſant; but it ſoon began to warm and ſcald both his palate and throat; which induced him to look upon it as an improper purgative.

This tree was introduced here before 1733, by William Houſtoun, M. D. [e].

PROPAGATION AND CULTURE.

It is propagated by ſeeds, which ſhould be ſown early in the ſpring, in pots filled with light rich earth, and plunged into a hot-bed of tanner's bark. If the ſeeds are freſh, the plants will appear in about five or ſix weeks after the ſeeds are ſown. As the plants will advance very faſt, where due care is taken of them, they ſhould have a large ſhare of freſh air admitted to them in warm weather, otherwiſe they will draw up too weak. When the plants are about two inches high, they ſhould be tranſplanted each into a ſeparate ſmall pot filled with light rich earth, and plunged again into the hot-bed of tanner's bark, being careful to ſhade them from the heat of the ſun, until they have taken new root; after which time they muſt have free air admitted to them, by raiſing the glaſſes in proportion to the warmth of the ſeaſon, and ſhould be frequently, but gently, watered. When the plants have filled theſe ſmall pots with their roots, they muſt be ſhaken out of them, and their roots trimmed, and then placed in larger pots, which ſhould be filled with the like rich earth, and plunged again into the hot-bed, where they ſhould remain till michaelmas, provided the plants have room, without touching the glaſſes, at which time they muſt be removed into the bark-ſtove, and plunged in the warmeſt part thereof: during the winter ſeaſon they muſt be ſparingly watered, for as the plants have ſucculent ſtalks, much moiſture will rot them; they muſt alſo be kept very warm, otherwiſe they will not live in this country. In ſummer they muſt have a large ſhare of freſh air in warm weather, but they muſt not be removed into the open air, for they are too tender to live abroad in the warmeſt part of the year in this country.

[b] Young's Ann. 22. 299.

* Juſſieu gen. [a] Browne. [b] Long. jam. 3. 844.
[c] Diſſ. alt. ſuria. [d] Hort. kew. from Mill. dict. vol. 2. 1739.

This plant is now pretty common in the Engliſh gardens, where there are collections of tender plants preſerved, ſome of which are grown to the height of twelve or fourteen feet, and many of them have produced flowers, but there has not been any of their fruit produced as yet in England.

As theſe plants have ample leaves, which are of a beautiful green colour, they afford an agreeable variety among other tender exotic plants in the ſtove; for where they are kept warm, and duly refreſhed with water, they retain their leaves all the year in verdure.

[It is much cultivated in Jamaica, for its beauty, and the fine ſhade it yields. It loves a deep rich ſoil, and thrives beſt near water[1].

HYACINTHO AFFINIS. See *Agapanthus* & *Hemanthus*.]

HYACINTHUS. *(of Pliny. Τακινθος of Theophraſtus and Diſcorides. Fabled to have ſprung from the blood of Hyacinthus, when he was accidentally ſlain by Apollo with a quoit; or from that of Ajax. DESCRIPTIONS, *&c.*

1. Root a roundiſh bulb, the ſize of a nutmeg. Scape from ſix inches to a foot in height, upright, round, ſmooth and ſolid, bowed down when it begins to flower. Leaves four, ſix or ſometimes more, only half the length of the ſcape, and about half an inch broad, keeled, hollow, ſmooth, ſhining, graſs green, flaccid, bending downwards, ending in an acute point. Flowers in a long raceme or ſpike, from eight to twelve, often more, all pointing one way, pedicelled, pendulous, ſweet-ſmelling, of a blue or violet colour, varying to white and fleſh-coloured, ſix-parted to the very baſe. Bractes two to each flower, lanceolate or awl-ſhaped, and nearly upright. This part was little obſerved before the time of Linnæus; Ray, however, remarks it here, and calls it *ligula*: he ſays there are two to each flower, of a violet-colour, longer than the pedicel, one larger than the other. Filaments adhering to the ſegments of the corollas, every other of them almoſt to the anthers: the three longeſt are equal to the tube of the corolla. Anthers upright, incumbent, ſomewhat arrow-ſhaped. Germ conical whiriſh. Style at top of a bluciſh colour. Stigma villoſe, moiſtened with a drop of liquor, according to Linnæus, and having club-ſhaped glands, according to De Necker. The honied pores, which Linnæus gives as the eſſential character of the genus, are not diſcoverable in this ſpecies. The valves of the capſule are ovate, and terminate in a ſhort point. Seeds numerous, of a fine blue colour, with a poliſhed ſurface [a].

The abſence of the nectariferous pores, the very deep diviſions of the corolla, almoſt forming ſix diſtinct petals, and the ſtructure of the other parts of the fructification induce Dr. Withering to wiſh that Linnæus had arranged this plant under the genus Scilla. The corolla ſhrivelling and not falling off, and the ends of the petals being rolled back, ſeem to conſtitute the only obſervable differences. Dr. Stokes alſo thinks it has more of the habit and even ſtructure of Scilla than of Hiacinthus. The drooping of the flowers diſtinguiſhes it from Scilla campanulata, a plant often found in our gardens, and flowering at the ſame time [b].

Native of France, Flanders, Switzerland, Italy, Spain, Perſia. It adorns our woods, coppices, and hedge-rows, with its flowers in the ſpring months. Mr. Curtis remarks that the ſeeds are not ripened till the end of the year; and, that on being ſown, they did not vegetate till the ſecond year.

The fanciful term of non ſcriptus was applied to this plant by Dodonæus, becauſe it has not the Ai, Ai on the petals, and therefore is not the Hiacinthus poeticus. Our old botaniſts name it Anglicus and Engliſh Hyacinth from its extreme commonneſs in many parts of our Iſland. Gerarde calls it blue Harebels or Engliſh Jacint; and it is the azur'd Harebell of our Poet in his Cymbeline [c]. In French it is *Jacinte des bois*; and in German, *Niederländiſche*, or *Engliſche Hyacinthe*.

Dr. Withering ſays that the freſh roots are poiſonous. According to Gerarde, they are "full of a ſlimy "gleweſh juice, which will ſerve to ſet feathers upon "arrowes inſteed of glew, or to paſte bookes with: "whereof is made the beſt ſtarche, next unto that of "Wake robin rootes."

Engliſh Hyacinth with blue flowers is very abundant in many places. Carnation and white are not ſo common. Gerarde found them by Colcheſter in Eſſex, by Southfleet near Graveſend, and near Canterbury in Kent, about Bath in Somerſetſhire, and Warrington in Lancaſhire: With white flowers it was alſo remarked by Ray in Scadbury Park, Kent; and by Dr. Stokes near Worceſter. In the incloſures about Streatham and other places in Surry.

2. This agrees with the firſt ſort in habit and appearance, but it is ſmaller, and differs in having the leaves more linear or leſs lanceolate, and more erect; the raceme is more nodding; the corollas fleſh coloured, not blue, rounder, with the ſides of the petals leſs ſpreading, flat at the baſe, not marked with a raiſed line on the back, and leſs rolled back (though ſtill reflex), than in that. The piſtil is ſhorter than the ſtamens: and the two bractes are of a deeper carnation [d]. The corolla ſwells out at the baſe in this, which it does not by any means in the preceding [e].

Native of Spain. Cultivated in 1759, by Mr. Miller [f]; who looks upon it as a variety of the firſt, differing principally in having the flowers of a bluiſh peach colour. Ray alſo obſerves that it is not very unlike the preceding, and that Caſpar Bauhin did not ſeparate them. Parkinſon makes them one, under the title of Engliſh Hares-bels, or Spaniſh Iacinth.

Mr. Miller's third ſort, which he abſurdly calls *H. utrinque floribus*, ſeems to be a variety of this. He ſays] it has blue flowers, diſpoſed on every ſide the ſtalk, which riſes about nine inches high, that the thyrſe of flowers is large when the roots are ſtrong, that it is a Native of Spain and Italy, and that it was formerly preſerved in gardens, but having been neglected for the fine varieties of the Eaſtern Hyacinths, it is now ſeldom ſeen but in old Gardens. [This is the caſe with many of our old favourites, which are caſt out daily to make room for new comers, inſomuch that many of the plants which were moſt known in the time of Caſpar Bauhin are now ſtrangers to us.

[a] Curt. lond. Ray hiſt. With. Stokes. Relh.
[b] Curtis & Stokes. [c] Act 4. ſcene 2.
[d] Linn. ſpec. [e] Linn ſyſt. [f] Hort. Kew.

3. Bulb ovate-conical, ſolid, covered with brown ſkins. Scape ſingle, a foot high, ſmooth. Leaves channelled, ſheathing the ſcape at the baſe, ſhorter than the ſcape, ſharp at the end. Flowers in a raceme, all pointing the ſame way, drooping a little; each on a ſhort peduncle, with an awl-ſhaped bracte at the baſe. Corolla of a dull greeniſh red colour [s.] When the flowers firſt appear, of a light blue, but fading to a worn out purple colour, according to Miller. [In Gerarde they are deſcribed as of a very duſky colour, as it were mixt with purple yellow and green, and as having no ſmell. In Parkinſon, who calls it Spaniſh dunne-coloured Jacinth, as of a purpliſh yellow colour, with ſome white and green as it were mixed among it. Ray obſerves, that plants which he raiſed from ſeed of the ſame root, varied in the colour of their flowers, ſome being duſky, and others almoſt green.

They are tubular at the baſe; the three outer ſegments ovate-linear, ſeparated almoſt to the bottom, and recurved, the three inner united into a tube, ſpreading a little at top. Filaments inſerted into the baſe of the corolla [h]. Capſule globular-three-cornered, produced at the baſe into a ſhort, conical peduncle, of a leathery-cruſtaceous ſubſtance, opening only at top. Seeds about ten in each cell, ſuborbiculate, bracted, flat on both ſides, ſurrounded with a retuſe rim, very dark coloured, and ſhining a little [i].

Native of Spain near Aranjuez, and of Barbary, about Fez and Morocco. Parkinſon ſays the African plant is in all reſpects greater than the Spaniſh.

With us it flowers in june, and from its flowering later than the other Hyacinths had the name of *ſerotinus* given it by Cluſius. Mr. Miller ſays it flowers early in the ſpring, which muſt be a miſtake with reſpect to England; though in Spain Cavanilles affirms that he has found it in flower on the 20th of april.

Mr. Miller cultivated it in 1759 [k].

4. This is of the ſame ſtature with the next ſpecies, but the corolla is green, with the three outer ſegments, which are placed alternately with the three inner, double their length, and ending in a very narrow point. Native of the Cape [l.]

5. This has a ſmaller flower; the petals are cut half their length, and are reflex at the brim; the lower part is cilindrical, a little ſwelling at the baſe, and of a deeper blue.

[The root, according to Cluſius, is the ſize of a ſmall olive, covered with a brown ſkin. Leaves five or ſix, longer and narrower than in the firſt ſort, ſtriated and keeled, lying moſtly on the ground. Scape ſlender, a long ſpan in height, round, ſmooth, glaucous, having ſix or ſeven flowers at top (Ray ſays, ſometimes twelve or more), nodding on pedicels half an inch in length; they are bright blue, ſmaller than thoſe of the firſt ſort, without any ſcent. Moſt of them, ſays Parkinſon, have white ſtripes and edges; and they vary to pure white, and a fine delayed (pale) red colour, with deeper-coloured veins running along the three outer ſegments.] Mr. Miller ſays, it was formerly called Coventry blue Hyacinth by the gardeners.

Native of Spain, [Italy and Ruſſia.—Flowering in april and may. Cultivated by Miller in 1759 [m].

6. This is one of the ſpecies found at the Cape of Good Hope by Thunberg, with ſeveral others, of which we have no deſcriptions. See n. 11, 16, 17, 18.

7. The Garden or Oriental Hyacinth has a large coated bulb, viſcid, and of a ſweetiſh taſte, from the bottom of which ſpring the roots, which are long, round fibres, of a middling thickneſs; from the midle of it a ſingle naked ſtem or ſcape; and from the top ſix, ſeven or more leaves. The leaves are broadiſh, keeled, pale green at bottom, but of a darker green towards the end. The ſcape is a long ſpan in height, ſmooth, roundiſh, pale green below, but tinged with brown towards the top: from the middle of this to the top come out the flowers one above another, not pointing the ſame way, as in the Harebell, but ſtanding on different ſides of the ſtalk; there, four, or five to twelve or more in number, each nodding on pedicels, half an inch in length, uſually of a very dark green colour, and having a pair of ſmall bractes at the baſe; the corolla is near an inch in length, almoſt cylindrical except at the baſe, where it ſwells or bellies out, and at the top the ſegments are turned back a little. Theſe flowers have a very ſweet ſmell, and are much valued for the variety of their colours, as pure white, white tinged with blue, all ſhades of blue from theſe to the dark violet, and all ſhades of red purple from the faint bluſh to the deep red; they are alſo ſometimes yellow. Culture and great attention have alſo brought the plants to be very ſtrong, and the flowers to be very large and double.

The Garden Hyacinth is a native of the Levant. It is very abundant about Aleppo and Bagdat, where it flowers in february [n]. Lepechin found it not only with purple, but with yellow flowers in Ruſſia [o]. With us it flowers in march and april; and was cultivated by Gerarde in 1596 [p]. Probably earlier; ſince neither he nor Parkinſon ſpeak of the Hyacinth as a flower then new in cultivation.

Gerarde figures only two varieties, the blue ſingle, and what he calls the double, but which is only many-flowered, and alſo the blue or ſky-coloured; but he mentions alſo the purple and the white.

Parkinſon, in 1629, has eight Oriental Hyacinths.

1. The white winter Orientall Jacinth.
2. The purple ditto.
3. The greateſt or Zumbul.
4. The ordinary (common) Orientall Jacinth, of different colours and ſhades.
5. The buſhy ſtalked Orientall Jacinth.
   And three Double ones, viz.
6. The bleake Orientall Jacinth, once double. Green at firſt, but of a blueiſh white when open, retaining ſome ſhew of greenneſs, with the brims of the petals white.
7. The fair (handſome) double blue, or purple.
8. The pure white double.

Johnſon, in his edition of Gerarde's herbal, 1633, has ten, viz.

1. Blue Orientall Jacinth: figured in f. 4. both in flower and ſeed.
2. Many-flowered. f. 5.—blue.
3. The other many-flowered, white. f. 6.
4. Reddiſh purple. f. 7.
5. White. f. 8.
6. Winter Jacinth. f. 9.
7. Leafy-ſtalked. f. 10.
   And three Double ones, viz.
8. Greeniſh-flowered.
9. Blue.
10. Milk White.—Only one of theſe is figured f. 11.

Parkinſon and Johnſon had theſe three double flowers from Cluſius's Curæ poſteriores, and Beſler's Hortus Eyſtettenſis, in which latter work they are figured: and they were all that were then known.

I do not find more than theſe enumerated in Rea's Complete Florilege, publiſhed in 1702. And Mr. Miller ſays that] we formerly had no other varieties in the Engliſh gardens, but the ſingle and double white and blue flowering; that from the ſeeds of theſe there were a few others raiſed in England, and alſo by the Flemiſh gardeners, who came over annually with their flower-roots to vend in England; but that the gardeners in Holland have within the laſt fifty years raiſed ſo many fine varieties, as to render the former of little or no value.

Double flowers ſeem not to have been in much eſteem, long after the Hyacinth had attracted the notice of the floriſts. For though Swertius in his Florilegium, printed in 1620, has figured about forty varieties of this flower, yet he has not one that is double. And Peter, the grandfather of the preſent George Voorhelm, of Haarlem, cultivated the Hyacinth a conſiderable

[s] Cavanilles. [h] Ibid. [i] Gærtner.
[k] Hort. kew. [l] Linn. ſpec. [m] Hort. kew.
[n] Gron. orient. [o] Reich. in fyſt.
[p] Hort. kew.

ſiderable time, before he attached himſelf to double flowers. The beauty of this celebrated flower was then ſuppoſed to conſiſt in the regularity and equality of the petals, and the uniformity of the colours. The double Hyacinth was in no more eſteem then, than the double Tulip is now; and Peter Voorhelm was accuſtomed to throw them out of his collection, till having been ill, and not able to viſit his flowers till they were going off, there remained by accident a bulb with double flowers, which fixed his attention, not for any ſuperior excellence it poſſeſſed, for it was ſmall, and of no remarkable beauty, but probably becauſe it was alone. He cultivated it, however, and increaſed it by offſets. Floriſts appeared who were fond of it, and gave him a good price for it. This muſt have been probably towards the end of the laſt century. He then ſet himſelf to cultivate Hyacinths with double flowers with as much zeal as he had ſhewn before in caſting them out. The firſt double flower he raiſed was named *Mary*; this variety is loſt, as well as the two next that were produced. *The King of Great Britain*, which is now looked upon as the oldeſt double Hyacinth, appeared about the beginning of the preſent century; it was greatly preferred to all the flowers then known, and the price of it was conſiderably more than 1000 florins. From this time the greateſt attention has been paid at Haarlem to the raiſing and culture of this beautiful flower: and ſuch has been the rage for it, that from one to two thouſand Dutch florins have been given for a ſingle root; that is, from near one to two hundred pounds ſterling.

The Haerlem gardeners diſtinguiſh near 2000 Hyacinths by name, and generally publiſh catalogues of them from year to year. New varieties are annually produced, and whole acres together are covered with this flower in the circuit of that town alone [a].

They are diſtributed into claſſes from their colours; the principal of which are blue, red, purple and white, with ſome yellow; they are ſubdivided from the ſhades of each colour, as of the blues deep blue, violet blue, blue purple, porcelain blue, agate blue, ſky blue, french gray, &c.; of the reds deep or full red, roſe-coloured carnation, &c.: alſo from the mixtures of different colours or ſhades, as light blue with a deep blue or purple eye; light red with a deep red eye; white, with a roſe-coloured, blue, purple or yellow eye, white and red of different ſhades, and blue, violet or purple of different ſhades mixed; yellow with a purple eye, &c. Some alſo have their petals ſtripped with a paler or deeper colour: and all theſe varieties are found both in ſingle and double flowers; but the latter only are now much regarded among floriſts, unleſs it be for producing ſeeds, by which alone they can procure new varieties.

The principal properties of a fine double Hyacinth are the following.

1. The ſtalk ſhould be tall, ſtrong and upright. The flowers, or bells as the floriſts call them, ſhould be ſufficiently numerous, each ſuſpended by a ſhort ſtrong peduncle, in a horizontal poſition; the whole having a compact pyramidal form, with the crown or uppermoſt flower perfectly erect.

2. The flowers ſhould be large, and well filled with broad bold petals, appearing to the eye rather convex, than flat or hollow: they ſhould extend to about the middle of the ſcape or ſtalk.

3. The plain colours ſhould be clear and bright, and ſtrong are in general preferred to pale colours; ſuch as are mixed ſhould blend with elegance.

8. Leaves linear, very narrow, commonly three, ſhorter than a finger's length. Scape very ſhort, terminated by a corymb of purple flowers, cloven half way down. Three ſtamens the length of the corolla, and the other three half the length. Style the length of the corolla. Native of the Cape of Good Hope, in paſtures. Obſerved by Koenig [b].

9. Leaves very long, the width of the finger. Raceme long, round, with very numerous flowers. Pedicels the length of the flowers. Bractes minute, membranaceous, awnleſs. Flowers white, cut beyond the middle. Filaments broad-lanceolate, oppoſite to the ſegments of the corolla. Anthers blue [c].

Native of Italy. Obſerved by Capelier in gardens and fields about Rome.—Introduced in 1786, by Mr. John Græfer. It flowers here in may [d].

10. The tenth ſort has pretty large oval, bulbous roots, from which ariſe ſeveral leaves, which are about eight or nine inches long, and half an inch broad; they are incurved a little on their ſides, and end in obtuſe points; theſe embrace each other at their baſe; out of the middle of theſe, the ſtalk which ſuſtains the flowers ariſes; it is naked below, but the upper parts are garniſhed with ſmall flowers growing in a ſpike; theſe have ovate pitcher-ſhaped petals, which are reflexed at their brim, and are of an aſh-coloured purple, or obſolete colour, ſeeming as if faded, but have an agreeable muſky ſcent: theſe ſtalks do not riſe more than ſix inches high, ſo the flowers make no great appearance; but where they are in ſome quantity, they will perfume the air, to a conſiderable diſtance. This ſort flowers in april, and the ſeeds ripen in july.

Of this there are two varieties, one of which has the ſame coloured flowers with this here enumerated, on the lower part of the ſpike, but they are larger, and have more of the purple caſt, but the flowers on the upper part of the ſpike are yellow, and have a very grateful odour. The Duch gardeners title it Tibcadi Muſcari. As this is ſuppoſed to be only a ſeminal variety of the third, I have not enumerated it as diſtinct. There is another variety of this with very large yellow flowers, that has been raiſed from ſeeds in Holland, which the floriſts there ſell for a guinea a root.

[It is a native of the Levant: Linneus ſays beyond the Boſphorus, whence it was brought into Europe before 1554. It was cultivated here in 1597, according to Gerarde [e].

11. Flowers without leaves, yellow. Found at the Cape of Good Hope by Thunberg [f].]

12. The twelfth ſort has a large bulbous root, from which come out ſeveral plain leaves a foot long, and about half an inch broad at their baſe; they are ſmooth, and end in obtuſe points. The flower-ſtalks riſe near a foot and a half high; they are naked at the bottom for about ſeven or eight inches, above which the panicles of flowers begin, and terminate the ſtalks. The flowers ſtand upon peduncles which are more than an inch long, each ſuſtaining three, four, or five flowers, whoſe petals are cut into ſlender filaments like hairs; they are of a purpliſh blue colour, and having neither ſtamina nor germ, never produce ſeeds. It flowers in may, and, after the flowers are paſt, the ſtalks and leaves decay to the root, and new ones ariſe the following ſpring.

[Native of the South of Europe. Linneus ſuſpects it to be a variety of the next ſpecies. It was cultivated here in 1629, according to Parkinſon [g].]

13. Bulb as large as a middling onion, [ovate, ſolid and white, covered with a purpliſh ſkin.] Leaves five or ſix, a foot (or eighteen inches) long, and three quarters of an inch broad at the baſe, diminiſhing gradually to a blunt point; [linear, channelled, bright green.] The flower-ſtalk riſes about a foot (or eighteen inches) in height, [round, upright, ſmooth, glaucous green.] The lower half is naked, but the upper part [has a looſe raceme of flowers, frequently for a foot in length. The lower flowers are farther aſunder, before they flower they are upright, but whilſt they flower, and afterwards, they ſtand out horizontally, on pedicels half an inch in length; their colour is a yellowiſh green, with blue or purple at the end; theſe are fertile. The upper ones are ſmaller, barren, ſtand upright, form a corymb, and are blue or violet, as are alſo their long pedicels [h]. Parkinſon ſays, "the whole "ſtalke with the flowers upon it, doth ſomewhat reſemble a long purſe taſſel, and thereupon divers "gentlewomen have ſo named it."

Native

Native of the South of Europe, in corn fields.] Mr. Miller says he had both roots and seeds from Spain and Portugal. [John Bauhin and Ray both observed it near Geneva; and I found it at Chatelaine near that city in flower on the 21st of april, 1779.] It flowers with us the end of april and beginning of may. It varies with white and with blue flowers, but the purple is most common.

Gerard, who cultivated it in 1596, calls it Faire haired Iacint; Parkinson, Great purple Faire-haired Iacinth; and Mr. Curtis, Two-coloured or Tassel Hyacinth. It is distinguished more by its singularity than its beauty, and by the difference between the lower and the upper barren flowers.]

14. This sort grows naturally in the vineyards and arable fields in France, Italy, and Germany, and where it is once planted in a garden, it is not easily rooted out, for the roots multiply greatly, and if they are permitted to scatter their seeds, the ground will be filled with the roots. There are three varieties of this, one with blue, another with white, and a third with Ash-coloured flowers: the first has a small, round, bulbous root, from which come out many leaves about six inches long, which are narrow, and their edges are incurved, so as to be shaped like a gutter: between these arises the flower-stalk, which has a close spike of blue sessile flowers at the top: they smell like new starch, or the stones of plums when fresh.

[Mr. Miller probably intends by this the next species, with which it is frequently confounded.

The leaves are three lines wide, straight on account of their short petioles. The spike has from twenty to thirty flowers. The teeth of the corolla are white, and the uppermost are small [a].

According to Scopoli, it has the appearance of Anthericum autumnale, the leaves rolled into a cylinder, the raceme (or spike) an inch long, the flowers nodding, sweet-smelling, scarcely longer than their proper pedicels.

It differs from the next species, in having the leaves upright, the bunch of flowers smaller, the flowers themselves larger, rounder, of a paler and brighter blue.

Parkinson enumerates three varieties, the white, the bluish-coloured and the branched; the first is frequently imported with other bulbs from Holland; the last seems to be a curious variety, and was obtained, according to Clusius, from the white [b]. The grape Hyacinth was cultivated by Gerarde in 1596 [c]. He calls it Great Grape-flower. Parkinson, Skie-coloured Grape-flower. It is now seldom met with but in long-established gardens.

15. Bulb small. Leaves keeled, very narrow, a line or little more in breadth, cylindrical, on account of the weakness of their petioles loose and decumbent, rolled round and twisted in a variety of ways. Scape a span high, blue under the flowers, compressed at top, terminated by a close globular spike or raceme of from forty to fifty flowers, of a very dark blue, with a three-cornered white mouth; they are imbricated downwards, have very short peduncles, a sweetish smell, somewhat like new starch, or plums, or Iris graminea, and have generally a single very short bracte at the base of each; the upper ones are barren [d]. They sometimes vary to white, according to Haller.

Native of the South of Europe, in corn fields. I gathered it in flower near Geneva, april the 8th, 1779. It was cultivated by Gerarde in 1596 [e]. He calls it Blew Grape-flower; and Parkinson, drake blew Grape-flower. Mr. Curtis names it Starch Hyacinth. This is much more common in our gardens than the botryoides, and flowers in april and may [f].

Mr. Miller's racemosus seems to be the Muscari; and his botryoides this species.

16, 17. Found at the Cape of Good Hope by Chevalier Thunberg, along with the revolutus, *n.* 6. corymbosus, *n.* 8. and convallarioides, *n.* 11.]

PROPAGATION AND CULTURE.

1. The first sort, being common in many parts of England, is seldom admitted into gardens.

2. The second also is in very few gardens.

3, 5. The case is the same with the third and fifth sorts. Since so many fine flowers have been raised from the seeds of the Eastern Hyacinth, these have been almost totally neglected.

Such as are desirous to preserve them need not be at much trouble about it, for their roots propagate in great plenty in any soil or situation, and require no other care, but to take up their roots every second or third year, soon after their leaves decay, and to plant them again in autumn: for if they are permitted to remain longer in the ground, their roots will multiply so much as to render their flowers very small and weak. They may all be increased either by seeds, or offsets from the old bulbs; the latter method only is practised with the above sorts.

The Garden or Eastern Hyacinth.

The Eastern Hyacinth is propagated by seeds or offsets from the old bulbs; the former method has been but little practised in England till lately, but in Holland and Flanders it has been followed for many years, whereby they have obtained a very great variety of the most beautiful flowers of this sort: and it is owing to the industry of the florists in those countries, that the lovers of gardening are so agreeably entertained, not only with the curious variety of this, but of most other bulbous rooted flowers.

The method of raising these flowers from seed is as follows: having provided yourself with some good seed (which should be saved from either semi-double, or such single flowers as are large, and have good properties) you must have a parcel of square shallow boxes or pots, with holes in their bottoms to let off moisture, which must be filled with fresh light sandy soil, laying the surface very level; then sow your seeds thereon as equally as possible, covering them about half an inch thick with the same light earth; the time for this work is about the middle or latter end of august. These boxes, or pots, should be placed where they may enjoy the morning sun only until the latter end of september, at which time they should be removed into a warmer situation, and towards the end of october they should be placed under a common hot-bed frame, where they may remain during the winter and spring months, that they may be protected from hard frosts: though they should be exposed to the open air when the weather is mild, by taking off the glasses. In the latter end of february or the beginning of march, the young plants will begin to appear above ground, at which time they must be carefully screened from frosts, otherwise they will be soon destroyed when they are so young; but you must never cover them at that season but in the night, or in very bad weather; for when the plants are come up, if they are close covered, they will draw up very tall and slender, and thereby prevent the growth of their roots. About the middle of april, if the weather proves good, you may remove the boxes out of the frame, placing them in a warm situation, observing, if the season be dry, to refresh them now and then gently with a little water, as also to keep them very clear from weeds, which would soon overspread the tender plants, and destroy them, if permitted to remain.

Towards the beginning of may these boxes should be removed into a cooler situation; for the heat of the sun at that season would be too great for these tender plants, causing their blades to decay much sooner than they would naturally do, if they were screened from its violence. In this shady situation they should remain during the heat of summer, observing to keep them constantly clear from weeds; but you must not place them under the dripping of trees, &c. nor should you give them any water after their blades are decayed, for that would infallibly rot the roots. About the latter end of august you should sift a little light rich earth over the surface of the boxes, and then remove them again into a warmer situation, and treat them, during the winter, spring, and summer months, as was before

directed: and about the middle of auguſt following you ſhould prepare a bed of light rich ſandy ſoil, in proportion to the quantity of your ſeedling plants; and having leveiled the ſurface very even, you ſhould take the earth from the boxes in which your plants were raiſed, into a ſieve, in order to get out all the roots, which by this time, (if they have grown well) will be about the thickneſs of a ſmall quill; theſe roots ſhould be placed upon the bed at about two or three inches aſunder, obſerving to ſet the bottom part of their roots downwards; then cover them over two inches thick with the ſame light earth; but as it will be impoſſible to get all the ſmall roots out of the earth in the boxes, you ſhould ſpread the earth upon another bed equally, and cover it over with light earth; by which method you will not loſe any of the roots, be they ever ſo ſmall.

Theſe beds muſt be arched over with hoops, and in very hard froſty weather they muſt be covered with mats, &c. to protect them from froſt; and in the ſpring, when the green leaves are above ground, if the weather ſhould be very dry, you muſt refreſh them with water; but do this ſparingly, for nothing is more injurious to theſe bulbs than too great quantities of moiſture. During the ſummer ſeaſon you muſt conſtantly keep the beds clear from weeds; but after the blades are decayed, you muſt never give them any water; and in autumn you ſhould ſtir the ſurface of the bed with a very ſhort hand-fork, being exceeding careful not to thruſt it ſo deep as to touch the roots, which, if hurt, are very ſubject to periſh ſoon after. Then ſift a little freſh, light, rich earth over the bed about an inch thick, or ſomewhat more, and in winter cover them again (as was before directed.) In this bed the roots may continue two years, obſerving to treat them, both in ſummer and winter, as before; then the third year the roots ſhould be carefully taken up a little before their leaves decay, laying the roots horizontally in the ground to ripen for three weeks, after which they may be kept out of the ground till the end of auguſt, when they ſhould be planted into new beds prepared as before, placing them at the diſtance of ſix inches aſunder; in theſe beds the roots may remain till they flower, during which time they ſhould be treated as before, with this difference only, that inſtead of covering them with mats in the winter, the ſurface of the ground ſhould be covered with tanners bark.

When their flowers begin to ſhew themſelves, you ſhould mark all ſuch as appear to have good properties, by thruſting a ſmall ſtick down by each root; which roots, at the time for taking them up, ſhould be ſelected from the reſt, and planted by themſelves; though I would by no means adviſe the rejecting any of the other roots, until they have blown two years, before which you cannot aſcertain their value. When the green leaves of theſe plants begin to decay, their roots muſt be taken up, and a bed of light earth, in a ſhady ſituation, ſhould be raiſed into a ridge; the better to ſhoot off the moiſture, the roots ſhould be laid into the earth again in an horizontal poſition, leaving the green leaves hanging out of the ground from the roots, whereby the great moiſture contained in their very ſucculent leaves and flowers-ſtalks may be exhaled, and prevented from returning to the roots, which, when ſuffered ſo to do, is very often the cauſe of their rotting after they are out of the ground. In this ridge the roots ſhould remain until the leaves are quite dried off, when they muſt be taken up, and after being cleared of all manner of filth, which would be hurtful to them, they muſt be laid up in boxes, where they may be preſerved dry until ſeptember, which is the proper ſeaſon for planting them again; the method of doing this ſhall be hereafter mentioned, when we treat of the management of old roots.

I ſhall now proceed to the culture of ſuch Hyacinths as have either been obtained from Holland, or are of our own product from the ſeeds of ſuch flowers as were very beautiful, and worthy to be preſerved in collections of good flowers: and it has been the want of ſkill in the management of theſe noble flowers, which has occaſioned the ill ſucceſs moſt people have had with them in England, whereby they have been neglected, ſuppoſing their roots to degenerate after they have flowered in England, which is a great miſtake; for were the roots managed with the ſame art as has been practiſed in Holland, I am fully convinced they would thrive near as well in England as there, or elſewhere, as I have experienced; for from ſome hundreds of roots which I have received from Holland at two or three different times, I have had a very great increaſe of their roots, which were as large, and produced as many flowers upon their ſtems, as the ſame ſorts generally do in Holland.

The ſoil in which theſe flowers ſucceed beſt, is a light, ſandy, freſh, rich earth, which may be compoſed after the following manner: take half freſh earth from a common, or paſture land, which is chiefly of a ſandy loam; this ſhould be off the ſurface, and not taken above eight or nine inches deep at moſt; and if you take the turf, or green ſward with it, it will ſtill be better, provided you have time to let it rot before it is uſed; to this you ſhould add a fourth part of ſea-ſand, and the other fourth part of rotten cow dung; mix theſe well together, and caſt it into a heap, where it may remain until you uſe it, obſerving to turn it over once in three weeks or a month, that it may be well mixed. If this compoſt is made two years before it is uſed, it will be much the better; but if you are obliged to uſe it ſooner, then it ſhould be oftener turned, that the parts may the better unite.

This ſoil ſhould be laid two feet deep on the beds which are deſigned for Hyacinths, and if you lay a little rotten cow dung, or tanners bark, at the bottom, which may be within reach of the fibres, but ſhould by no means touch the bulb, it will be better. If the ſoil is very wet where theſe beds are made, you ſhould raiſe them ten or twelve inches above the ſurface of the ground; but if it be dry, they need not be raiſed above three or four inches.

The manner of preparing the beds is as follows: Firſt, take all the former old earth out of the bed to the depth you intend, which ſhould be near three feet; then ſpread ſome rotten neats dung, or tan, in the bottom, about ſix inches thick, laying it very level; upon this you ſhould lay the above mentioned earth two feet thick, levelling it very even; then ſcore out the diſtances for the roots, which ſhould be eight inches ſquare, in ſtraight rows each way; after which, place your roots exactly in the ſquares, obſerving to ſet the bottom part downward; then cover the roots ſix inches deep with the ſame prepared earth, being very careful in doing this not to diſplace any of the roots; and if the tops of theſe beds are made a little rounding, to ſhoot off the wet, it will be of ſervice in moiſt ground, provided the middle of the beds be not made too high, which is a fault the other way.

The beſt ſeaſon for planting theſe roots is the middle or latter end of ſeptember, according to the earlineſs or lateneſs of the ſeaſon, or the weather when it happens; but I would adviſe you never to plant them when the ground is extremely dry, unleſs there be a proſpect of ſome rain ſoon after; for if the weather ſhould continue dry for a conſiderable time after, the roots will receive a mouldineſs, which will certainly deſtroy them. The beds will require no farther care until the froſt comes on very ſevere, at which time they ſhould have ſome rotten tan ſpread over them, about four inches thick; and if the alleys on each ſide of the bed are filled up, either with rotten tan, dung, or ſand, it will prevent the froſt from penetrating the ground on each ſide to the roots, and ſecure them from being deſtroyed; but when the winters prove very ſevere, it will alſo be proper to have ſome Peas-haulm, Straw, or ſuch like covering laid over them, which will keep out the froſt better than mats; and lying hollow, will admit the air to the ſurface of the ground, and alſo permit the exhalations to paſs off, whereby the earth will remain dry, and prevent the roots from rotting, which has often happened when the beds have been too cloſely covered. But you muſt obſerve to take off this light covering whenever the weather is mild, and only let it continue on in very hard froſts; for where the beds are covered with tan or ſea-coal aſhes, no-

common froſt can penetrate through, ſo the coverings are uſeleſs, except in very ſevere froſt; for a ſmall froſt cannot injure the roots before the green leaves appear above ground, which is ſeldom before the beginning of february, at which time the beds muſt be arched over with hoops, that they may be covered either with mats, canvas, or ſome other light covering, to prevent the froſt from injuring the buds as they ariſe above ground; but theſe coverings muſt be conſtantly taken off every day when the weather is mild, otherwiſe the flower-ſtems will be drawn up to a great height, and become very weak, and the foot-ſtalks of the flowers will be long and ſlender, and ſo rendered incapable of ſupporting the bells; which is a great diſadvantage to the flowers, for one of their greateſt beauties conſiſts in the regular diſpoſition of their bells. When theſe hoops are fixed over the beds, the rotten tan ſhould be moſt of it taken off them; in doing of which, great care ſhould be taken not to bruiſe or injure the leaves of the Hyacinths, which by that time will be breaking out of the ground with the flower-ſtem, therefore the tan ſhould be removed by the hands; or if any inſtrument is made uſe in the doing of it, there muſt be great caution how it is performed.

When the ſtems of the flowers are advanced to their height, before the flowers are expanded, you ſhould place a ſhort ſtick down by each root, to which, with a wire formed into a hoop, the ſtem of the flowers ſhould be faſtened, to ſupport them from falling; otherwiſe, when the bells are fully expanded, their weight will incline them to the ground, eſpecially if they are not ſcreened from the wind and rain.

During their ſeaſon of flowering they ſhould be covered in the heat of the day from the ſun, as alſo from all heavy rains; but they ſhould be permitted to receive all gentle ſhowers, as alſo the morning and evening ſun; but if the nights are froſty, they muſt be conſtantly defended therefrom. With this management you may continue your Hyacinths in beauty at leaſt one whole month, and ſometimes more, according to their ſtrength, or the favourableneſs of the ſeaſon.

When their flowers are quite decayed, and the tops of their leaves begin to change their colour, you muſt carefully raiſe the roots out of the ground with a narrow ſpade, or ſome other handy inſtrument; this is what the Dutch gardeners term lifting of them: in the doing of this, the inſtrument muſt be carefully thruſt down by the ſide of the root, being careful not to bruiſe or injure it, as alſo to put it below the bottom of the root; then by the forcing of this inſtrument on one ſide, the fibres of the root are raiſed and ſeparated from the ground. The deſign of this is to prevent their receiving any more nouriſhment from the ground: for by imbibing too much moiſture at this ſeaſon, the roots frequently rot after they are taken up: about a fortnight after this operation the roots ſhould be entirely taken out of the ground, and then carried to beds ſituated where the morning ſun only ſhines upon them; the earth of the beds ſhould be looſe and raiſed into a ſharp ridge, laying the roots into it in a horizontal poſition, with their leaves hanging out, by which means a great part of the moiſture contained in their thick ſucculent ſtalks and leaves will evaporate; which, if it were permitted to return back to the roots, would cauſe them to rot and decay after they are taken up, which has been the general defect of moſt of the Hyacinths in England.

In this poſition the roots ſhould remain until the green leaves are entirely decayed, which perhaps may be in three weeks time. This is what the Dutch gardeners term the ripening of their roots, becauſe by this method the roots become firm, and the outer cover is ſmooth, and of a bright purple colour; whereas thoſe roots which are permitted to remain undiſturbed, till the leaves and ſtalks are quite decayed, will be large, ſpongy, and their outer coats will be of a pale colour; for the ſtems of many of theſe flowers are very large, and contain a great quantity of moiſture, which, if ſuffered to return into the roots, will infallibly cauſe many of them to periſh. After they are ſo ripened, you muſt take them out of the ground, and wipe them clean with a ſoft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie ſingly, and be expoſed to the air, but they muſt be preſerved carefully from moiſture; nor ſhould they be ſuffered to remain where the ſun may ſhine upon them; in this manner they may be preſerved out of the ground until ſeptember, which is the ſeaſon for planting them again, at which time you muſt ſeparate all the ſtrong flowering roots, planting them in beds by themſelves, that they may make an equal appearance in their flowers; but the offſets and ſmaller roots ſhould be planted in another ſeparate bed for one year, in which time they will acquire ſtrength, and by the year ſucceeding will be as ſtrong as the older roots.

The ſingle and ſemi-double flowers ſhould be planted alſo in a bed by themſelves, where they ſhould be carefully ſheltered (as was directed before) from the froſt, until the flowers are blown; at which time their covering ſhould be entirely removed, and they ſuffered to receive the open air, but the flower-ſtalks ſhould be ſupported with ſticks; which, though the weather may ſoon deface the beauty of the flowers, yet is abſolutely neceſſary to promote their ſeeding; and when the ſeeds are quite ripe, you muſt cut off the veſſels and preſerve them, with the ſeeds therein, until the ſeaſon for ſowing it. But you muſt obſerve, that after theſe flowers have produced ſeeds, they ſeldom flower ſo well again, at leaſt not in two years after; ſo that the beſt method to obtain good ſeeds is, to plant new roots every year for that purpoſe. Although theſe roots are, by moſt perſons, taken up every year, yet if the beds are well prepared for them, they may remain two years in the ground unremoved, and the roots will increaſe more the ſecond year than the firſt, though the flowers are more liable to degenerate: therefore thoſe who cultivate theſe for ſale, take up their roots annually when they are large and ſaleable; but the offſets and ſmall roots, they uſually leave two years in the ground.

There are ſome perſons who let their Hyacinth roots remain three or four years unremoved, by which they have a much greater increaſe of roots, than when they are annually taken up; but the roots by this great increaſe are frequently degenerated, ſo as to produce ſingle flowers; therefore I ſhould adviſe the taking up of the roots every year, eſpecially thoſe of the moſt valuable kinds, which is the moſt certain method to preſerve them in their greateſt perfection, though the increaſe may not be ſo great; and if theſe roots are planted a fortnight or three weeks earlier in the autumn than is before directed, it will cauſe them to produce ſtronger flowers; and thoſe roots which are annually removed, will be rounder and firmer than ſuch as ſtand two years unremoved.

Obſerve that if the bulbs of double Hyacinths be planted ſooner than the middle of octobor, they will be apt to come up during the winter, and thus be injured by ſevere froſts; and if it be deferred later than the middle of november, the bulbs will begin to put out fibres, which will weaken them.

The beds ſhould be in a dry airy part of the garden, with a ſouthern expoſure ſheltered from the north and eaſt, ſix feet diſtant at leaſt from the fence, and made ſloping a little towards the ſun.

Florifts differ as to the proportion of the materials of the compoſt in which the bulbs are to be planted. Some inſtead of half freſh earth, recommend only one third, with the ſame quantity of rough ſea or river ſand, and the remaining third part to be one fourth old rotton cow-dung, and the reſt the earth of decayed leaves. Some put in tanners' bark, rotten wood or old ſawduſt. Others reprobate tan, as retaining an aſtringency which is pernicious to delicate bulbous flowers.

In uſing freſh earth from a paſture it is neceſſary to guard againſt the wire-worm, by minutely inſpecting the heap as it is turned over, and picking out this deſtructive creature, which is of a yellow colour, and about an inch in length.

Perſons who are nice about their flowers erect a covering or awning over them during the time of flowering, to keep off the rain without excluding the light, and to ſhelter them from cold winds, which are frequently

quently very injurious at the early ſeaſon when theſe delicate flowers are in bloom. This awning ſhould be of coarſe linen on a frame of wood, made to roll up eaſily, that in mild cloudy weather the flowers may have the full benefit of the ſun and air: and it ſhould not continue on more than a fortnight or three weeks, for it weakens the bulbs.

Hyacinths never require any water; moderate rains are ſufficient for them after planting and till they bloom; and when they have paſt their bloom heavy rains ſhould be kept from the bulbs by hoops covered with mats.

Such bulbs, as are four or five years old flower ſtrongeſt in England; and after this gradually decline: but in Holland the ſame bulb will produce bloom twelve or thirteen years together, nor is it ever known to die merely from age.

The Hyacinth ſucceeds beſt in ſituations near the ſea. In more inland parts the floriſt muſt introduce freſh bulbs annually to ſupply his deficiencies; and keep a reſerve in narrow deep pots to fill up the vacancies in his beds.

Single Hyacinths may be planted a week or two ſooner than the double ones, and thus will bloom two or three weeks earlier than the latter.

Upon theſe you muſt depend for ſeed, for the double ones rarely produce any. Save your ſeeds from thoſe plants which have ſtrong ſtraight ſtems, and a regular well-formed pyramid of flowers, which are ſemi-double: and do not gather it till it is perfectly black, when the pericarp will appear yellow on the outſide, and begin to open. Then cut off the ſtem, and place it in a dry, airy, cool place till the time of ſowing; which is either the end of October or the beginning of march. (Mr. Miller recommends auguſt.) By the ſixth year after ſowing, all the bulbs that ſurvive will have produced their bloom, and if one in five hundred ſhould deſerve to be recorded in the annals of the Floriſt, the cultivator may eſteem himſelf fortunate.]

The Grape-Hyacinths or Muſcari.

Theſe are hardy, will thrive in the open air, and require no other culture but to take up the roots every ſecond or third year, to ſeparate the bulbs; for ſome of them multiply faſt, and when the bunches of bulbs become large, they do not flower ſo ſtrong. They ſhould be taken up ſoon after their ſtalks and leaves decay, and ſpread on a mat in a dry ſhady room for a fortnight, to dry, after which they may be kept in boxes till Michaelmas, when they may be planted in the border of the flower-garden, and treated in the ſame way as the common Hyacinths.

They are all eaſily increaſed by offſets, which moſt of them ſend out in plenty; ſo that there is no occaſion to ſow the ſeeds, unleſs it be to gain new varieties.

[The botryoides and racemoſus, which are very much alike, being troubleſome from their great increaſe, and the former not flowering readily in an open border, it is a good method to plant the bulbs in moderately ſized pots, filled with light earth, and to plunge them in the borders to flower: in the autumn they ſhould be taken out, and the offſets thrown away. The latter is much the moſt common in our gardens, and is frequently miſtaken for the botryoides[a].

DESCRIPTIONS, *&c.*

1. This has a ſpreading woody root, which produces ſeveral ſoft, pithy, woody ſtems, from three to four feet high; they are four-cornered when young, and have a green bark, but as they grow older they become taper, and have a light-brown bark. Leaves at each joint oppoſite, three inches long, and two broad near the baſe, pointed, ſerrate; they are deep green above, and pale underneath, with many tranſverſe veins; the petioles are about an inch long. Flowers terminating, in a cyme. Corolla ſmall, white, having an agreeable odour.

[The flowers have ſometimes eight ſtamens only according to Du Roi.

The calyx is ſaſtened to the pericarp, which is a ſmall capſule, almoſt hemiſpherical; marked with ten ſtreaks, flattiſh above, not opening by valves, but by a central hole between the ſtyles. Partition membranaceous, pervious at top when ripe. Seeds about twenty in each cell, compreſſed like a lens, netted-veined, brown[d].

Linnæus had deſcribed the capſule as opening between the horns formed by the two permanent ſtyles; we are at a loſs to know why in his firſt manuſſa he corrected this, and affirmed that the capſule is what he terms *circumciſſa*, or cut round horizontally into two hemiſpheres. Gærtner however ſuggeſts, that although in all his ſpecimens the capſules opened by a hole at top, yet in ſome it may be otherwiſe, and they may

[a] Curtis.

[b] Withering, 4 p. 334. and Bulliard. [c] Gærtner.

ſplit

split in half horizontally: of this we have an instance in Heuchera.

Native of Virginia and Canada. Introduced in 1736, by Peter Collinson [a].]

The flowers appear towards the end of july, and in auguſt, but ſeldom perfect their ſeeds in England.

[2. This has a ſomewhat ſhrubby ſtem, branched, and growing to the height of about five feet: the leaves are broad, heart-ſhaped, ſerrated, and ſharp-pointed: they are foot-ſtalked and ſtand oppoſite, and the lower ſurface is downy and of a ſilvery appearance.

Gathered in Carolina by T. Walter, Eſq. and in Florida by Mr. J. Bartram [b].

3. Root fibrous, much branched, whitiſh. Stems ſeveral growing together, erect, ſhrubby, branched, round, with a ſmooth brown bark. Branches oppoſite, each pair croſſing the others, round, ſmooth, leafy, green with dark purple ſpots, flowering at the top. Leaves oppoſite, ſpreading and curved backwards, obtuſely pointed, entire towards their baſe, bright green, pale beneath: foot-ſtalks ſhort and thick, ſmooth, pale, channelled above. Cymes terminating, the ſize and figure of the common Guilder-Roſe, and like that almoſt entirely compoſed of radiated abortive flowers, of a beautiful roſe-colour, inodorous, green when young as well as in decay. Flower-ſtalks variouſly ſubdivided, ſmooth, ſometimes hairy: partial ones of a deep roſe-colour, roundiſh. Bractes none, except a few leaves about the baſe of the cyme, reſembling thoſe on the branches, but ſmaller. Calyx in a luxuriant ſtate of deformity, very large, compoſed of four (rarely three or five) ſpreading, unequal, obovate leaves, which are entire, ſmooth, roſe-coloured, ſlightly ribbed and permanent. Petals generally four, nearly equal, ſmall, obovate, concave, the colour of the calyx, fading. Filaments eight, ſometimes ſix or ten, as long as the corolla, ſpreading, awl-ſhaped, red. Anthers didymous, grayiſh with yellow pollen. Germ wanting. Styles two or three, (rarely one) nipple-ſhaped, ſtanding cloſe together, purple, half as long as the ſtamens. Stigmas blunt.

At the diviſions of the cyme are ſometimes found a few more complete five-cleft flowers, having a ſmall five-toothed calyx, three ſpreading ſtyles, and an inferior germ conſiſting of three cells; but theſe flowers wither away without coming to maturity. If the fruit ſhould prove a capſule with many ſeeds, the plant will belong to this genus; but if it ſhould be a berry, with a ſingle ſeed when ripe, it muſt be referred to the genus Viburnum; there is every appearance however of its being an Hydrangea.

It is much valued on account of the great profuſion of its very elegant flowers, which are monſtrous in the ſame manner as the Viburnum Opulus or European Guilder-Roſe.

Its native place is unknown. It is commonly cultivated in the gardens of China and Japan, whence it was introduced at Kew by Sir Joſeph Banks, Bart. in 1790 [c].

Loureiro ſays, that on diſſecting the germ, and viewing it with the microſcope, it appeared to be many-ſeeded, which confirms the idea of its being an Hydrangea.]

PROPAGATION AND CULTURE.

1. This is eaſily increaſed by parting the roots at the end of october, which is alſo the beſt time to tranſplant them. It ſhould have a moiſt ſoil, for it grows naturally in marſhy places; and requires no other culture, but to keep the plants clean from weeds, and to dig the ground between them every winter. If in ſevere froſts the ſtalks are killed, they will put out new ones the following ſpring.

[3. This beautiful plant being very eaſily increaſed by cuttings, has been pretty generally diffuſed within the compaſs of a few years. The ſoil that it thrives beſt in is a good rich loam. Some trials have been made with it to ſtand abroad; and it is hardy enough in a ſheltered ſituation and warm ſoil to endure moſt of our winters; but it does not flower ſo well in the open air as in a greenhouſe. The Garden Hydrangea therefore muſt be conſidered rather as a greenhouſe plant than a hardy one; and ſuperfluous plants only ventured in the open borders of the flower-garden.

The ſecond ſort has not yet been introduced among us.

SPECIES.

1. Hydraſtis canadenſis. *Canadian Yellow-root.*
Lin. ſpec. 784. *Reich.* 2. 674.]
Warnera canadenſis. *Mill. dict.—fig.* 190. *t.* 285.
Hydrophyllum verum canadenſium. *Lin. ſpec. ed.* 1. 146.

DESCRIPTION, *&c.*

The root is compoſed of thick fleſhy tubers, of a deep yellow colour within, but covered by a brown ſkin, ſending out fibres from ſeveral parts in the ſpring. It ſends up one or two ſtalks about nine inches high, at their firſt appearance of a light green, but afterwards changing to a purpliſh colour, and hairy towards the top. Each ſtalk has one or two leaves, the lower petioled, but the upper embracing; they are ſix or ſeven inches in diameter, and are deeply cut into three, four, or five lobes, which are irregularly ſerrate: they are of a light green in the ſpring, but change afterwards to a deep green, with ſome dark ſpots or marks and after the flower is decayed turn to a purpliſh colour. The ſtalk is terminated by one flower, which is white, and of very ſhort duration, ſeldom continuing above three or four hours after it is expanded. The fruit is red and ſucculent; [a compound berry like the Raſpberry and Mulberry; not at all like the Strawberry in ſtructure.

According to Linneus, this plant reſembles the Hydrophyllum. Leaves on each ſtalk two, petioled, emarginate at the baſe, palmate, ſerrate, the lobes having a ſmall lobe on each ſide of them.

Juſſieu ſays it has the fruit and habit of a Rubus, and is allied to Podophyllum.

Native of Canada. It was cultivated in 1759, by Mr. Miller, and flowers in may and june [a].]

PROPAGATION AND CULTURE.

This plant not increaſing much, is rather uncommon in the Engliſh gardens; it delights in great ſhade and moiſture; and when planted in dry ground, or much expoſed to the ſun, it rarely lives through one ſummer. In a moiſt loamy ſoil and ſhady ſituation, if it be left undiſturbed three or four years, it will flouriſh.

DESCRIPTION, *&c.*

Root of many long, thick, white fibres. Leaves at each joint of the ſtalk, ſix or eight together, floating, roundiſh, kidney-ſhaped, fleſhy, ſmooth, thick, perfectly entire, almoſt tranſparent, reddiſh underneath, marked with a few circular, and many tranſverſe veins; they are about an inch and half in diameter, and when dry, on removing the outer ſkin, a moſt beautiful cloſe net-work of veins is ſeen. Leaf-ſtalks from three to ſix or ſeven inches long, round, ſmooth, thick, tranſparent, having numerous croſs bars. Sheaths in plants of both ſexes numerous, next the root, ovate, tranſparent; in the male plant there is alſo a pair about the middle of the flower-ſtalk, containing the tender unopened bloſſoms as in a bladder. Flower-ſtalks the ſame length with the leaf-ſtalks, upright; in the male producing three or four flowers, in the female only one. Corolla white, with a yellow bottom, a little wrinkled and tender. Calyx yellowiſh. Stamens ſometimes more than nine, as far as twelve. Anthers almoſt linear, two-celled. The nectary conſiſts of three yellow glands, crowning the germ.

This plant increaſes by runners, furniſhed with pendulous gems, ſupported on long foot-ſtalks. Theſe gems conſiſt of two ſtipulaceous ſcales, folded together, within which are curiouſly enveloped the embryo leaves of the future plant.

Native of many parts of Europe, in deep ditches, and ſlow ſtreams, with a muddy bottom, multiplying itſelf greatly by runners which ſhoot out to a great length, and at the joints drop down long roots, which penetrate deep into the mud. It flowers from june through the autumn*.

ß. Ray found it with a double flower ſmelling very ſweet, in a ditch by the ſide of Audrey cauſeway, cloſe by the great wooden bridge, in the iſle of Ely, plentifully †.

* Curtis, Lightf. Woodw. in With. Pollich, Linn. fuec.

HYDROCOTYLE. (*From* Ὕδωρ, *water, and* κοτυλη, *a ſmall cavity, veſſel or cup. Becauſe it grows in water, and the leaves are hollow; or the leaves being hollow contain water.*)

Nat. order of *Umbellatæ* or *Umbelliferæ*.

GENERIC CHARACTER.

CAL. *Umbel* ſimple.
Involucre commonly four-leaved, ſmall.
Perianth ſcarcely any.
COR. *univerſal* uniform in figure, not in ſituation: *Florets* all fertile.
Proper five-petalled: *Petals* ovate, acute, ſpreading, entire.
STAM. *Filaments* five, awl-ſhaped, ſhorter than the corolla. *Anthers* very ſmall.
PIST. *Germ* upright, compreſſed, orbiculate, inferior, peltate. *Styles* two, awl-ſhaped, very ſhort. *Stigmas* ſimple.
PER. none. *Fruit* orbiculate, compreſſed, tranſverſely bipartite.
SEEDS two, ſemiorbiculate, compreſſed.

ESSENTIAL CHARACTER.

Umbel ſimple, with a four-leaved involucre. *Pet.* entire. *Seeds* ſemiorbiculate-compreſſed.

Lin. syst. 272. *suppl.* 177.
Leaves five-parted goosed.

14. Hydrocotyle erecta.
Lin. syst. 272. *suppl.* 177.
Leaves cordate crenate, scapes few-flowered the length of the petioles.

15. Hydrocotyle moschata.
Forst. flor. austral. n. 135.
Leaves kidney form seven-lobed serrate villose, umbels many-flowered.

DESCRIPTIONS, &c.

1. Roots perennial, capillary, whitish. Stem creeping, round, smooth, striking root at the joints. Leaves orbicular, smooth, glossy, bright green, about an inch in diameter, waved, scalloped or somewhat lobed and notched on the edge, the center a little depressed, and marked with a white dot; the veins form a kind of net-work on both surfaces. Leaf-stalks about two inches long, upright, round, smooth, naked below, above beset with bristly, horizontal, distant hairs. Common peduncles single, axillary, from the base of the leaf-stalks, little more than an inch in length, upright, round, slender, naked or slightly hairy, terminated by two umbels or glomerules, one springing out of each other, each containing from four or five to six and nine florets, which are very small, reddish white or rose-colour, on very short pedicels. There are two roundish, membranous white stipules at the base of each peduncle, and a very minute narrow tapering leaflet is placed under each floret. Seeds of a pale brown colour [a]. Linneus remarks, that this plant has a simple umbel proliferous from the centre, and the two styles distant.

Native of most parts of Europe in marshes, also in Japan, and Jamaica, but not common. It flowers with us from may or june through july and august. The flowers being very small, and hidden by the leaves, are not much remarked, though they are abundant in their season; but the plant is easily known by the petiole of the leaf being inserted into the middle of it, a circumstance uncommon in European plants.

Gerarde calls this plant Water Penny-wort, Sheep-killing Penny-grasse, Penny-rot; in the north country, he says, it is called White-rot, to distinguish it from the Red-rot or Drosera; in Norfolk Flowkwoort (from its being supposed to occasion the Flukes in the liver of rotten sheep:) and by the husbandmen Sheep's-bane, because it killeth sheep that do eat thereof. This however is a vulgar error; for the rot in sheep is owing to their feeding in wet grounds; and perhaps to an insect (Fasciola hepatica) which from its shape is called a Fluke (or Flounder), and abounds in such situations, adhering to stones and plants, as well as in the livers and biliary ducts of sheep affected with the rot. This plant, together with Drosera or Sundew, and Pinguicula or Butterwort, is common in marshy places, and therefore the disorder has been attributed to these; but it is pretty certain that neither sheep nor any other quadruped feed on these plants.

In German it is called *Wassernabel, Sumpfnabel.* In Dutch, *Waternavel.* In French, *Hydrocotile commune, le Goblet, l'Ecuelle d'eau, l'herbe des Patagons.* In Spanish, *Sombrera de agua.*

β. The Italian floating Hydrocotyle has very slender simple fibres collected into a head, issuing from the joints of the stems, and fastening themselves into the mud. Stems horizontal, thick, even, fleshy, tinged with brownish red horizontal, jointed, floating. A single leaf comes out from each joint, on petioles a span long or more, curved inwards, thick at the base, fleshy, growing thinner at the top; the leaves are kidney-form, crenate-lobed or repand, with five large lobes, the middle one small, the two or three others with three-lobed notches; in front they are cut to the very center with a scarcely gaping sinus, as in H. americana. All of them are floating. Flowers from five to ten, small, collected into a head. Seeds compressed, semiorbiculate. The peduncles are three inches long, and issue from the joints of the stem.

The leaves are not peltate and emarginate, as in the common sort, but kidney-form and subbilobate, the stems thick, and the petioles very fleshy. It seems to approach nearer to H. americana [b].

Native of Italy.

2. Roots filiform, capillary, branched, whitish. Leaves radical, peltate, orbiculate, crenate-gashed, smooth, veined, on smooth round petioles, from two to five inches, and often in watery places a foot long. Peduncles also radical, the length of the petioles, round. Flowers in umbels, hermaphrodite. Involucre scaly, with ovate minute leaflets. Umbel simple; pedicels numerous, erect, one-flowered. Corolla acute, reflex, white. Styles contiguous at the base, the length of the petals. Fruit roundish, compressed, striated [c].

According to Linneus it is very like the common sort, and has been confounded with it; but it differs in having the scape twice as long as the leaves, and more than twenty florets in a simple umbel.

Native of Jamaica, in marshes, of several parts of the continent of America, and also of Cochinchina; if the plant which these authors describe be the same.

3. This has the appearance and size of the first. The leaves are cut in front to the very centre with a sinus that scarcely gapes, and are divided at the edge into nine obsolete lobes, each of which has three smaller notches. Umbel five-flowered [d]. This description seems to accord with Columna's plant, (t. 3.) and that may perhaps be the same with this, or a variety of it.

Native both of North and South America, and the East Indies.

4. Native of Hispaniola [e].

5. This differs from the fourth species in having the toothlets or notches round the leaves equal, the substance also of the leaves is twice as thick, and they are almost hoary, and there are several together at each joint of the stalk, whereas in that they are single [f].

Native of the East Indies, Japan, the Cape of Good Hope, Jamaica, &c, Introduced here in 1774, by Mr. Francis Masson [g].

6. This is of the same size with the foregoing sorts. Stem creeping. Leaves even, blunt, flat, often two at a joint. Scapes the length of the leaf. Umbel many-flowered.—Native of China [h].

7. Root fibrous. Leaves petioled, undivided, quite entire, resembling those of the sweet Violet (Viola odorata), mucronate, tomentose, both at the roots, and about the extremities of the stems, which are prostrate, and have flowers at the ends with the leaves. Peduncles several, filiform, shorter than the leaves, one flowered. Flowers small.—Native of the Cape of Good Hope.

[a] Curtis. Withering. [b] Cyrillo. [c] Swartz. [d] Linn. spec. [e] Swartz. [f] Linn. spec. [g] Hort. kew. [h] Linn. spec.

8. Stems creeping. Leaves alternate, three-nerved, quite entire, acute, petioled: ſtipules linear, acuminate, flowers axillary, peduncled.—This alſo is a native of the Cape of Good Hope.

9. Found at the Cape of Good Hope by Thunberg [1]. Of this we have no deſcription.

10. This is like the preceeding, but the leaves are much longer; the peduncles more ſlender and alſo longer.—Found at the Cape of Good Hope by Thunberg [2].

11. Root cauleſcent, branched on the ſurface of the earth. The whole plant hoary tomentoſe. Stems an inch long, ſcarcely branched. Leaves alternate, petioled, gaſhed and ſeven-toothed. Peduncles lateral next the the lower leaves, and of the ſame length with them. Receptacles of the flowers very dark purple. Petals white [3].

The central flower being fertile (having ſix ſtamens and a piſtil), and being ſurrounded by barren flowers, Linneus made a diſtinct genus of it, placed it in the order Monoecia of the claſs Polygamia, and named it *Solandra*, from the amiable and learned D. C. Solander, L. L. D., who found it at the Cape of Good Hope; in the Supplement, however, and in the 14th edition of the Syſtema it is removed into this genus, with which it certainly agrees in habit. Gærtner thus deſcribes the fructification: Umbel pedicelled. Involucre four-leaved, linear, the length of the fruit, tomentoſe on the outſide. Florets four or ſix, barren, peduncled in the circuit, and a ſingle one in the centre becoming a ſeſſile fruit; which is ovate, gibbous, compreſſed on the ſide, twin, whitiſh. Seeds ſemiovate, turgidly lenticular, with five ſharp ribs, and in the intervals between theſe netted with tranſverſe nerves.

12. This is very like the preceding, but differs in having linear leaves, narrower towards the baſe, with three equal teeth at the end; not ovate and five or ſeven-toothed, as in that; peduncles much ſhorter than the leaf, not equal in length; ſtem ſhorter, woolly, herbaceous, not woody and proſtrate. The central is certainly hermaphrodite in this.—Found at the Cape of Good Hope by Sparrmann [4].

13. Stem creeping, jointed. Leaves ſolitary or two together; the diviſions three-lobed and blunt, as in Ranunculus. Petioles frequently the length of the finger. Scapes cauline, an inch long. Umbel ſimple Petals white.—Found in Mexico by Mutis.

14. Leaves ſharply toothed on the ſides, an inch in length; petioles radical, a ſpan long, hairy at the top. Scapes radical, the length of the plant, erect as is the whole plant, not creeping, and having a few flowers at the top.—Native of Jamaica [5].

15. Native of New Zealand [6].

   Campanula americana ſpinoſa & hirſuta, flore patulo & ſeſſili cæruleo. *Houſt. Mſs.*
   Stem ſpiny, leaves oblong hirſute, flowers three-ſtyled axillary.

DESCRIPTIONS, *&c.*

1. Stems upright, a foot high with alternate branches. Leaves lanceolate, ſeſſile, ſomewhat waved, viſcid. Spikes axillary, ſpreading. Flowers terminating, ſubſeſſile, few, cluſtered [7]. Capſule acuminate, with a groove on each ſide, membranaceous, very thin ſubdiaphanous. Partition ſimple, very narrow. Receptacle very large, fungoſe, hollowed with a groove into which the partition is inſerted, divided as it were into two hemiſpheres. Seeds ovate, attenuated towards the umbilicus, very obſcurely grooved, pale brownith red [8]. When the flowers are ſix-cleft and have ſix ſtamens, there are three ſtyles, and the capſule is three-celled and three-valved, with a three-ſided partition [9].

Native of South America.

2. Stem herbaceous, annual, one foot high upright, almoſt ſimple. Leaves lanceolate-linear, quite entire, ſmooth, ſeſſile, ſcattered. Flowers blue, on one-flowered peduncles. Calyx inferior. Corolla bell-ſhaped, with a ſhort tube, the ſegments nearly equal to the calyx. Filaments placed on the tube, ſhorter than the limb. Styles upright, ſhorter than the ſtamens. Seeds roundiſh, ſurrounding two ovate columns, adhering to the bottom of the capſule, free at top, as in Gentiana. The corolla is not properly wheel-ſhaped, but wheel-bell-ſhaped.

Native of Canton in China, in moiſt places.

3. Stem herbaceous, half a foot high, even, upright, branched. Leaves lanceolate, alternate, petioled, ſmooth, quite entire, ſpreading. Racemes erect, one from each axil of the leaves, ſimple, erect, the length of the leaves. Flowers alternate, on pedicels the length of the flowers [10].

It is thus deſcribed under the name of *Steris* in the firſt Mantiſſa. Appearance that of a ſmall Capſicum. Stem herbaceous, very much branched and even. Leaves alternate, petioled, oval-oblong, quite entire, ſharpiſh, even. Peduncles oppoſite to the leaves, axillary or terminating, ſubdivided or one-flowered. Corolla blue, the ſame ſize as that of Capſicum.

Native of the Eaſt Indies.

4. Native of the Weſt Indies [11].

SPECIES.

1. Hydrophylax maritima.
Lin. syst. 160. *suppl.* 126.

DESCRIPTION, &c.

It has the appearance of Arenaria rubra maritima, but is larger. Root simple, filiform, blood-red, long, fleshy, sweet. Stem creeping, filiform, smooth, coloured, jointed, sheathed with blunt membranaceous permanent sheaths, very long. Leaves opposite, spreading, ovate, acute, quite entire, approximating, fleshy, shining, roughened with very small, whitish, pellucid callusses; petioles short, membranaceous, margined, sheathing the stem, permanent; when the leaves fall these become permanent sheaths of the stalks; flowers axillary, subsessile, usually two together, but not opposite, erect; corolla pale blue; anthers blue.—Found by Koenig in driving sand on the sea shore near Guduluhr in the East Indies[a].

Leaves lobate-angular.]

DESCRIPTIONS, &c.

1. The root is composed of many strong fleshy fibres, which spread wide on every side: from this arise many leaves on foot-stalks five or six inches long, jagged into three, five or seven lobes, almost to the midrib; they are indented on their edges, having several veins running from the midrib to the sides, and are of a lucid green. The flowers rise with foot-stalks from the root, having one or two small leaves of the same shape with the lower; they are in loose clusters hanging down, of a dirty white, and making no great figure. [Capsule marked on each side with a shallow groove, and sprinkled all over with small white bristles. Receptacle globular, free, filling the whole cavity of the capsule, at first herbaceous and fleshy, divided into little cells equal in number with the nascent germs, afterwards membranaceous and spongy, rufescent, splitting in two with the capsule. Seeds regularly four, but often fewer, nestling in the receptacle, irregularly ovate and angular, elegantly netted with very minute excavations, yellowish white[b]. It flowers here in may and june, and the seeds sometimes ripen in august.

Native of Virginia and Carolina, on moist spongy ground. It was cultivated in 1739, by Mr. Miller.[c]] He supposes that Morinus gave it the title of Water-leaf, because in spring water stands in the cavities of the leaf, and not from its growing in water, as Tournefort conjectures.

[2. This has all the same structure with the preceding, and differs only in the leaves, which have the same shape with those of the Acer or Maple, half-five-lobed, smooth, with the lobes acute, slightly toothed, and having a sinus at the petiole, as in the leaves of Maple.

Native of Canada[d]. Cultivated by Mr. Miller in 1759. It flowers in may[c].]

PROPAGATION AND CULTURE.

These plants are very hardy in respect to cold, but they should be planted in a moist rich soil and shady situation: in a warm dry soil they will not prosper, unless they be constantly watered in dry weather. They may be increased by parting the roots in autumn; for if they are not well rooted before spring, they will require abundance of water.

DESCRIPTION, *&c.*

This is a very large ſpreading tree in the Weſt Indies, where it grows in great plenty; it has a large ſtem, covered with a ruſſet bark, which divides into many ſpreading branches, garniſhed with ſmooth ſtiff leaves, which ſtand by pairs, their baſe joining at the foot-ſtalk, to which they ſtand oblique, one ſide being much broader than the other, the two outer ſides being rounded, and their inſide ſtraight, ſo that they reſemble a pair of ſheep-ſhears; they are pointed at the top, and ſtand alternately on the ſtalk. The flowers are produced in looſe ſpikes at the end of the branches, ſome of the ſhort ligneous foot-ſtalks ſupporting two, and others three flowers, which are compoſed of five yellow petals ſtriped with purple; the petals are ſhort and ſpread open; the ſtamina are much longer, and of a purpliſh colour; theſe flowers are ſucceeded by thick, fleſhy, brown pods, ſhaped like thoſe of the Garden Bean; they are ſix inches long, and two inches and a half broad, of a purpliſh brown colour, and a ligneous conſiſtence, with a large ſuture on both edges; they contain three or four roundiſh compreſſed ſeeds, divided by tranſverſe partitions, [and incloſed in a whitiſh ſubſtance of fine filaments, as ſweet as honey. The Indians eat this ſubſtance with great avidity, though it is apt to purge when freſh gathered; but it loſes this quality as it grows old.

Between the principal roots of the tree exudes a fine tranſparent reſin, yelloviſh or red, which is collected in large lumps, is called gum *Anime*, and makes the fineſt varniſh that is known, ſuperior even to the Chineſe *lacca:* for this latter uſe it is diſſolved in the higheſt rectified ſpirits of wine. It burns readily, and with a clear flame, emitting a grateful and fragrant ſmell, for which reaſon it is ſometimes ordered by way of fumigation in the chambers of perſons labouring with aſthmas or ſuffocative catarrhs. Its vapours not only ſtrengthen the head, but all parts of the body affected with cold. Some apply it outwardly, diſſolved in oil or ſpirits of wine, to ſtrengthen the nerves. An oil may be diſtilled from it, prevalent in palſies, cramps and contractions of the ſinews. The ſolution in ſpirits has been thought not inferior to Guaiacum in venereal caſes. A decoction of the leaves expels flatulencies, and gives eaſe in colichy pains, by gently opening the bowels; and the inward bark is an excellent vermifuge in ſubſtance or decoction.

The wild bees are fond of building their neſts in this tree, which grows to a conſiderable ſize, and is looked upon as excellent timber; but it muſt be very old before it is cut, otherwiſe the heart will be but ſmall[a].

It is in great requeſt for wheel-work in the ſugar-mills, particularly for cogs to the wheels, being extremely hard and tough, it is ſo heavy that a foot cube weighs about a hundred pounds, and it will take a fine poliſh[b].

Native of the Weſt Indian iſlands, and the continent of America. Cultivated here in 1739[c].]

PROPAGATION AND CULTURE.

It is eaſily raiſed from the ſeeds if they are freſh; theſe muſt be ſown in pots, and plunged into a hot-bed of tanners bark: there ſhould be but one ſeed put into each pot, or if there be more, when the plants appear, they ſhould be all drawn out to one ſoon after they come up, before their roots entangle, when it will be hazardous doing it; for if great care be not taken, the plant intended to be left may be drawn out with the other. As the roots of this plant are but ſlender, ſo they are very difficult to tranſplant; for unleſs a ball of earth is preſerved to their roots, they ſeldom ſurvive their removal, therefore they muſt be ſeldom tranſplanted from one pot to another. The plants muſt conſtantly remain in the tan-bed in the ſtove, and ſhould be treated the ſame way with other tender plants of the ſame country, giving but little water to them, eſpecially in the winter. When theſe plants firſt appear, they make conſiderable progreſs for two or three months, after which time they are at a ſtand perhaps a whole year without ſhooting, being in their growth very like the Anacardium, or Caſhew Nut, and very difficult to preſerve long in this country.

Orobanches ſpecies æthiopica. *Pluk. mant.* 142.

DESCRIPTION, *&c.*

Stem half a foot high, quite ſimple, woody, thick, cloſely imbricated with leaves, or rather ovate ſcales, convex on the outſide, ſmooth, blunt. Spike terminating, denſe, fleſhy, villoſe, the length of the ſtem, and three times as broad, imbricated with bractes and flowers. Bractes (one to each flower) ovate-oblong, hirſute on the outſide, the ſame length with the tube of the flowers, which are ſeſſile. The whole plant reſembles the Orobanche in ſtature, but it is blood red. The ſeven-leaved calyx, and corolla deſtitute of a lower lip, are ſufficient reaſons for the removal of this plant from the genus Orobanche.—It is a native of the Cape of Good Hope, and is paraſitical at the roots of ſhrubs[a].]

DESCRIPTIONS, *&c.*

1. Common black Henbane has long fleſhy roots, which ſtrike deep into the ground, and are branched. Bottom leaves ſoft, deeply ſtalhed on their edges, and ſpreading on the ground. The ſtalks, which do not riſe till the ſecond ſpring, have leaves of the ſame ſhape, but ſmaller, and claſping, and are about two feet high: on the upper part are flowers ſtanding on one ſide in a double row, ſitting cloſe to the ſtalk alternately.

[The whole plant is covered with unctuous fetid hairs. The corolla is yellow, or rather pale yelloviſh brown, beautifully netted with purple veins, and a dark purple eye or baſe: the ſhape is irregular, gradually tapering into the tube, with five prominent ribs on the outſide; the upper ſegment is the largeſt, the reſt gradually diminiſhing downwards; the upper inciſions are ſhallow, the lowermoſt extending half way to the baſe, and much wider than the reſt. Calyx a little diſtended on the under ſide, woolly at the baſe with long ſoft hairs, matted with thoſe of the flowers next above and below. Filaments white, with ſoft hairs below; the uppermoſt ſhorteſt, thoſe below gradually increaſing in length. Anthers and ſtyle of a fine deep purple. The capſules do not ſplit, as moſt others do, into two or more valves, but are covered with a lid, that rain, as Linneus expreſſes it, may not ſpoil the ſeeds. This lid, though it may eaſily be ſeparated with a knife, yet adheres ſo ſtrongly to the body of the capſule, that the ſeeds more frequently eſcape by the perforations of inſects, than from the falling of the lid. The calyx becomes rigid, and the capſules continue on the dead plant till the plants of the next year are in flower, when, the leaves being fallen off, the fruit appears in bunches pointing one way, in two rows from one ſide of the ſtem and branches. Seeds very abundant, gray, excavated and angular[a].

The whole plant has a ſtrong and peculiar odour, ariſing from the viſcid hairs with which it is covered, greatly affecting the head of ſome perſons, as ſoon as they come within its atmoſphere.

The root, herb, and ſeeds, taken internally, are reputed poiſonous, and well atteſted inſtances of their bad effects are recorded. Madneſs, convulſions, and death are the general conſequence. Dr. Smith ſays, he has often eaten the ſeeds with impunity[b] (and I have done the ſame, in ſmall quantities). Lightfoot affirms, that a few of the ſeeds have been known to deprive a man of his reaſon and limbs; relying probably on the relation of Haller, that one of his fellow pupils under Boerhaave at Leyden, in the year 1725, having eaten Aconite, Apocynum, and Belladonna with impunity, was at length taken in by the ſeeds of Henbane; loſt his reaſon and the uſe of one ſide, but his life was ſaved by Boerhaave. The ſeeds however are certainly not poiſonous.

Linneus affirms, that the roots have been frequently eaten for Parſneps, and have produced delirium and not unfrequently death.]

Mr. Miller informs us, that a mixture of theſe roots having been imported with Gentian, has been attended with very bad effects.

[Other relations of the narcotic[c] and poiſonous effects of the ſeveral parts of Henbane may be met with in almoſt all the authors who have treated of this naufeous plant.

Linneus ſays, it is not touched by any quadruped, except perhaps the goat, and that animal is not fond of it. Sheep, it is ſaid, will ſometimes eat it when young. There is a ſort of bug (cimex hyoſcyami) very common on it. Chryſomela hyoſcyami alſo feeds upon it. According to Linneus, the roots ſcattered about a houſe will drive away mice[d].

Henbane has been uſed medicinally from time immemorial; and there is no doubt of its being an uſeful

[a] Withering, Stokes in With. Pollich, Linn. ſuec. Lightf.
[b] Withering. [c] Fl. ſuec.

medicine

medicine under proper management. The Edinburgh college order the expreſſed juice of the plant to be evaporated to an extract; and perhaps in this ſtate it may be advantageouſly joined with opium, where the effects of the medicine are deſirable, and coſtiveneſs is to be avoided. The doſe is from half a ſcruple to half a dram[a]. Villars ſays, the extract may be given ſafely in a doſe of two or three grains, increaſing the quantity gradually; but that it ought to be prepared from the plant juſt going into flower, and in balneo mariæ; for it has neither odour nor activity, if the plant be young, or if the extract be made with an open ſtrong fire. He has adminiſtered it internally in epilepſy and convulſions, and found that it put off the fits, and diminiſhed their violence, but did not effect a cure. Stoerck and others after him have recommended it not only in the above diſorders, but in mania, hæmoptoe, the dry cough, but univerſally wherever an anodyne is wanting to quiet the nervous irritations: beginning with a ſingle grain of the extract, and increaſing the doſe gradually to five grains; ſome more daring practitioners proceed as far as fifteen grains; but in general perhaps it is more adviſeable to continue the uſe of the medicine longer than to give it in very large doſes. It has been even adminiſtered in a cataract, to the quantity of two grains, mixed with mercurius dulcis. The leaves bruiſed and fried have been applied with effect to the piles, and in muſcular ſpaſms. Like other narcotics they aſſiſt in ſoftening indurations of the glands. An oil expreſſed from the ſeeds is uſed outwardly as an anodyne: and the common people ſometimes ſmoke them for the tooth-ach; or put a piece of the root boiled in milk at the root of the tooth.] The roots alſo cut in pieces and ſtrung like beads, are uſed for anodyne necklaces to hang about childrens' necks, to prevent fits, and cauſe the teeth to breed eaſily. Some give a decoction of Henbane in clyſters to aſſwage the pains of the inteſtines, but this is dangerous[b]. In general it is a medicine not to be trifled with, or taken without good advice.

Henbane is a native of moſt parts of Europe, in waſte places, particularly near towns and villages, whence Linneus remarks that it aſſociates with mankind, like the magpie, and ſome other birds. It is generally known by its peculiar fetid odour. The Engliſh name Henbane is probably derived from a notion of its being noxious to poultry; but whether this notion be well founded or not, I have not had any opportunity of knowing.

In German it is *Bilſenkraut*. In Dutch, *Bilſenkruid*. In Daniſh, *Bulme*. *Honſebane*, &c. In Swediſh, *Bolmort*, *Honſabale*. In French, *la Juſquiame*. In Italian, *Giuſquiamo*, *Fava porcina*. In Spaniſh, *Beleno*, *Veleno*. In Portugueze, *Miemendro*, *Velenho*, *Toſciamo*. In Ruſſian, *Belena*.

A variety of this was found by Profeſſor John Martyn, near the Caſtle at Cambridge, about the year 1729, with the corolla and anthers of a pure brimſtone colour, without the leaſt tinge of purple. The ſeeds being ſown in the botanic garden at Cheliſea, produced the very ſame variety[c].

Henbane is a biennial plant, forming the root and lower leaves of the firſt ſeaſon, and the ſtem with the fructification the ſecond. It flowers in june.]

2. This riſes with a branching ſtalk two feet high. The lower leaves are regularly cut on both ſides into acute ſegments, which are oppoſite, but the upper leaves are entire. The flowers grow at the end of the ſtalk in bunches. They are of a worn-out red colour, and ſhaped like thoſe of the common ſort, but their tubes are ſwollen.

[The whole plant is ſmooth[d]. It reſembles common Henbane, but the ſtem-leaves are ovate, repand, more ſmooth above; the floral leaves ovate, ſeſſile, entire. Flowers on a very ſhort peduncle. Corolla bell-ſhaped, red, beautifully netted with dark veins[e].

Native of Egypt, of Syria near Aleppo, according to Rauwolff, and of the iſland of Crete or Candia, according to Cluſius. It is an annual plant, flowering in july, and was cultivated by Mr. Miller in 1731.

This ſpecies was left out in the twelfth, thirteenth, and fourteenth editions of Syſtema Vegetabilium, but is reſtored by Reichard, Retzius and others; unleſs it be the ſame with H. muticus, n. 5. and H. Datura of Forſkall[f].

3. White Henbane reſembles the Black in moſt circumſtances, but the leaves are more rounded or obtuſe, petioled, ſinuate, very ſoft, bearded with white hairs, as is alſo the ſtem. Flowers ſewer, the lower ones on longer peduncles, but the upper flowers have very ſhort ones. Calyx green, five-toothed, hairy. Throat of the corolla longer than in the firſt ſort; limb revolute, five-cleft, with unequal ſegments[g]. Capſule clothed with the calyx, membranaceous, knobbed with the portuberant ſeeds, ovate, ventricoſe at bottom, marked with a depreſſed ſtreak on each ſide. Receptacle fungoſe, ſcrobiculate, ovate-oblong, plano-convex, fixed on both ſides to the partition. Seeds very numerous, ſmall, compreſſed a little, incurved or kidney-form, cloſely ſcrobiculate, whitiſh aſh-coloured[h].

Native of the South of Europe. Annual. Flowering in auguſt. Cultivated here in 1570[i].

The corolla varies with the baſe dark purple, or green. Hence Miller has made two ſpecies, *major* and *albus*;] the firſt having the flowers on ſhort peduncles, of a pale yellow colour, with very dark purple bottoms, and growing naturally in the iſlands of the Archipelago: this is H. major, albo ſimilis, umbilico floris atro-purpureo. *Tournef. cor.* The ſecond has the flower in larger bunches, ſitting very cloſe on the ends of the branches, of a greeniſh yellow colour, with green bottoms. This is the white Henbane of the South of Europe. H. major, albo ſimilis, umbilico floris virenti. *Juſſieu.*

4. This is a perennial plant (biennial), with weak ſtalks, which require a ſupport. Leaves roundiſh, acutely indented on their edges, and on pretty long foot-ſtalks. The flowers come out at each joint of the ſtalk; they are large, and of a bright yellow, with a dark purple bottom. The ſtyle is much longer than the corolla. [The ſtem is hairy, and about a foot high. The petioles are very hairy. Leaves lobed, toothletted. Peduncles at the ſide of the petioles, erect with the flower, but quite bent down when in fruit. The outer lobe of the corolla is larger than the reſt, and the lower ſinus is cut beyond the limb, as in the Teucriums, and there the purple ſtamens with the very long piſtil iſſue and hang down[k].

Native of Candia, and other parts of the Levant.] It flowers moſt part of the ſummer, and ſometimes ripens ſeeds in the autumn. [Cultivated in 1640, by Parkinſon[l].

Proſper Alpinus and others make two varieties of this, differing only in ſize and the ſhade of colour in the corolla.

5. Stem a foot high, the thickneſs of a finger, erect, roundiſh, ſubpubeſcent; branches axillary, ſhorter. Leaves alternate, obtuſely ſinuated; acute, even, quite entire, paliſh, with pubeſcent petioles. Floral leaves ſubpetioled, ovate or ovate-oblong, entire, one or two to a flower alternately. Raceme of flowers all directed one way, curved in at top. Calyx bell-funnel-form, with broadiſh ſegments, not at all ſpiny. Corolla a little longer than the calyx, but not broader, ſubcampanulate, the three upper ſegments broader, the two lower ſmaller, deeply ſeparated; the colour on the outſide at firſt green, then whitiſh; on the inſide very dark purple, with the two loweſt ſegments whitiſh; but finally the whole corolla becomes white and unſpoted. Stamens declining, purple, a little longer than the corolla. Piſtil longer, declining. Native of Egypt and Arabia. Biennial[m].]

Miller deſcribes his minor as having a ſmaller ſtalk than the preceding, with joints farther diſtant; the

[l] Hort. kew. [m] Linn. mant.

leaves roundish, and deeply indented in obtuse segments, ſtanding upon pretty long foot-ſtalks; the flowers coming out ſingly from the ſide of the ſtalks, at a good diſtance from each other; of a yellow colour, with dark bottoms. It was brought from the Levant by Tournefort.

6. [This is an annual plant, a hand in height. Stem oblique, brittle, undivided, having long hairs. Lower leaves entire, upper oblong, toothed, alternate, ſparingly hairy, on petioles of the ſame length with themſelves. Peduncles ſhort on the outmoſt ſtem, each from the axil of two oppoſite leaves. Calyxes turbinate, ten-angled, almoſt the length of the corolla, and broader than its tube, ſpiny at top. Corolla yellow, with a dark throat, divided on the lower ſide beyond the limb. Stamens declining [1].

Gouan ſays, that the root-leaves in the wild plants are always bipinnatifid, with the ſegments ſharply toothed: but that it occurs alſo with lanceolate leaves, if the ſeeds be ſown very late, or be cultivated in a poor lean ſoil.

Native of Perſia. Cultivated in 1691 by Compton, Biſhop of London, at Fulham. It flowers in july [2].

7. Root perennial. Stems a foot high, ſimple, erect, round, rough-haired. Leaves alternate, petioled, cordate, lurid-green, veined, rough-haired underneath, the upper ones gradually larger. Flowers in bundles, terminating, pedunculed. Calyxes very ſhort, five-toothed, rough-haired. Corollas purpliſh, funnel-form, upright. Stamens a little ſhorter than the corolla, converging. Style the ſame length with the corolla. Stigma capitate, emarginate, whitiſh. It flowers early in ſpring. Native of Siberia [3].

It was introduced here in 1777, by Meſſrs. Gordon and Græffer [4].

The deſcription is repeated in the appendix to Linneus's Species plantarum, p. 1668. under Pulmonaria hirta.

8. Root perennial, tranſverſe, knobbed, thick, irregular, branched, flexuoſe, the thickneſs of the human thumb. Stem herbaceous, annual, upright, round, ſmooth, (ſcarcely more than a foot high, according to Linneus and Jacquin, but even three feet in height, according to Scopoli), the thickneſs of the human finger, trifid and bifid, with dichotomous branches, as in Atropa Belladonna. (Branches only two, according to Linneus, ſpreading, and entirely ſimple: or, as Jacquin ſays, ſubtrichotomous, with a groove running down from the leaves.) Leaves ovate and oblong, the length of the human finger; the lower quite entire; the upper frequently moderately ſinuate or repand. (According to Linneus, petioled, naked, ſomewhat wrinkled, ſpreading; on the ſtem alternate, ſolitary; under the forkings in threes, two of which approximate; on the branches alternate, but two together on the ſame tooth or baſe, one of which is a little leſs than the other. According to Jacquin they are ſubovate or lanceolate, entire except the lower ones, which in gardens at leaſt are ſinuate-toothed in front, veined, wrinkled, decurrent; the lower ones oppoſite, the reſt ſcattered.) Peduncles one-flowered, pendulous, from the axils; weak, two inches long. Calyx ſmooth, five-toothed, permanent, wider than the fruit, and as it were inflated: (bell-ſhaped, five-cleft, awnleſs. *Linn.*) Corolla of the ſame ſhape and colour as in Atropa Belladonna: (three times the length of the calyx, bell-ſhaped, ſlightly five-cleft, blunt on the outſide ſtriguinous, with a few pale ſtreaks, within yellow. *Linn.*—oblong, large, five-toothed, narrowing at the baſe into a ſhort tube, yellowiſh purple, deciduous. *Jacqu.*) Stamens attenuated, villoſe, (approximating to the ſtyle, bent down towards the lower ſide. *Linn.*—awl-ſhaped, unequal, upright, hirſute, ſhorter than the petal. *Jacqu.*) Anthers two-celled, pale yellow, (oblong, incumbent, large. *Jacqu.*) Style deciduous, longer than the ſtamens; terminated by a capitate, ſubbifid, pulvinated ſtigma, having a three-cornered aperture at top. Germ ſeſſile, ſmooth, (ovate, blunt, ſitting on the receptacle, with five nectareous toothlets round the baſe of it. *Jacqu.*) Capſule ſmaller than the calyx, five lines in diameter, not eaſily opening; the lid marked with two cruciform lines; (falling with the peduncle and calyx, and after it has fallen, opening tranſverſely. *Jacqu.*—ſubglobular, coriaceous, rufeſcent, cut round almoſt in the middle. *Gærtn.*) Seeds in each cell from twenty to twenty-four, fixed to an orbiculate receptacle [5]; kidney-form, rather large, elegantly dotted very cloſely in rows, with little holes, and of a very pale yellow colour [6]. It differs from Atropa, which it very much reſembles in habit, in the calyx, ſtigma, and nectareous teeth of the receptacle, but principally in its capſular fruit.

Frequent in the woods about Idria in Friuli, flowering about the middle of april [7]. It flowers with us in may; and was introduced in 1780, by Mr. Daniel Grimwood [8].

Jacquin, thinking that this plant is generically diſtinct from Solanum, with which the old authors had placed it; from Atropa, wherein Scopoli had put it in the firſt edition of his Flora Carniolica, and from Hyoſcyamus, made a new genus of it under the name of *Scopolia*, from Giov. Ant. Scopoli, phyſician at Idria, and afterwards profeſſor at Pavia: but he with ſingular modeſty declined the honour in the following words. "Veruntamen merita mea in re herbaria non ea eſſe "fateor, quæ me viris illis adnumerare queant, quo- "rum cognomina novis plantarum generibus data "fuerunt. Alii ſunt his honoribus longe digniores." Had only ſuch received this honour, the names of plants of this ſort would have been very few. Modern botaniſts, however, have agreed to conſider this plant as a ſpecies of Hyoſcyamus; and it has been reſerved to Dr. Smith to name a plant from this amiable and ſkilful naturaliſt.]

PROPAGATION AND CULTURE.

All theſe are biennial plants, which periſh ſoon after they have perfected their ſeeds. They flower in june and july, and their ſeeds ripen in the autumn, which, if permitted to ſcatter, will produce plenty of the plants the following ſpring; or if the ſeeds are ſown at that ſeaſon, they will ſucceed much better than in the ſpring; for when they are ſown in ſpring, the plants ſeldom come up the ſame year. They are all hardy except the ſecond ſort, and require no other culture but to keep them clean from weeds, and thin the plants where they are too cloſe. The ſecond ſort ſhould have a warm ſituation and a dry ſoil, in which it will live much better through the winter than in rich ground.

The fourth ſort is a perennial plant. If the ſeeds are ſown in pots as ſoon as they are ripe, and placed under a hot-bed frame in winter, the plants will come up in the ſpring; but if they are kept out of the ground till the ſpring, they rarely ſucceed. This ſort will continue ſeveral years, if it be kept in pots and ſheltered in winter, for it will not live in the open air at that ſeaſon, but only requires to be protected from froſt; therefore if theſe plants are placed under a common hot-bed frame in winter, where they may enjoy as much free air as poſſible in mild weather, they will thrive better than when they are more tenderly treated. This ſort may be eaſily propagated by cuttings, which, if planted in a ſhady border during any of the ſummer months, will take root in a month or ſix weeks, and may be afterwards planted in pots, and treated like the old plants.

GENERIC CHARACTER.

CAL. *common* cylindric-angular, conſiſting of about eight leaves, permanent; *ſcales* lanceolate, erect, acute, ſlightly keeled, equal; calycled at the baſe with fewer, very ſhort, cloſe ſcales.

COR. *Compound*, ſubimbricate, uniform; compoſed of many hermaphrodite corollets.

Proper one-petalled, ligulate, linear, truncate, five-toothed.

STAM. *Filaments* five, capillary, very ſhort. *Anther* cylindrical, tubular.

PIST. *Germ* oblong. *Style* filiform, the length of the ſtamens. *Stigmas* two, reflex.

PER. none. The common calyx cloſe or ſpreading.

SEED ſolitary, oblong, membranaceous, ſtreaked on one ſide along the middle, almoſt the length of the calyx.

ESSENTIAL CHARACTER.

Cal. almoſt equal. *Down* hairy and calycled. *Recept.* naked.

DESCRIPTIONS, &c.

1. Root perennial, ſingle, cylindrical, thick, woody, fetid. Leaves radical, ſmooth, pinnatifid or runcinate, cut into ſeveral triangular ſegments, which are almoſt equal and regular, ſometimes having a few teeth on the hinder ſide, terminated as well as the ſegments themſelves by a herbaceous ſpinule; nerve hairy. From the centre of theſe ſpring from ſix to ten ſimple, naked flowering-ſtalks or ſcapes, a little longer than the leaves, each terminated by a middle-ſized flower, yellow above, and red beneath. Calyx calycled, having five or ſix ſcales at the baſe, leſs by half than the others, which are a little open, ſmooth, and eight in number; each of theſe has two florets. Seeds naked yellowiſh, ſomewhat villoſe. Receptacle villoſe, flat. The whole plant has a diſagreeable ſmell. It has much reſemblance to Dandelion, but the flower is ſmaller, and of a deeper yellow colour [a].

Native of the mountains of Italy, Dauphiné, Carniola and Switzerland.—Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in July [b].

2. The peduncles and rachis of the leaves farinaceous; the lobes imbricately reflexed, toothed on both ſides, even. Seeds membranaceous, with a ſimple ſeſſile egret [c]. Allioni remarks, that the ſeeds in Hyoſeris are crowned, ſometimes with a down, ſometimes with awns or ſcales, but that the outſide ſeeds are naked in moſt of the ſpecies: in this, however, they are all crowned with down.

Native of the South of France, the county of Nice on hills near the coaſt, and of Spain. It was cultivated here in 1640 [d].

Allioni ſays it is an annual plant. By Linneus, and in the Kew catalogue it is marked as perennial.

3. This reſembles the preceding very much, but the leaves are thicker, ſomewhat fleſhy, lucid, and

[a] Linn. ſpec. Scop. Villars, Haller. [b] Hort. kew.
[c] Linn. ſpec. [d] Hort. kew.

more ſhortly toothed. Scapes purpliſh, longer than the leaves. Calyx angular. Marginal ſeeds ſcarcely downy[a].

According to Vahl, the wild plant, (which has a very different appearance from the cultivated one) is very ſmooth, a finger's length in height, with the ſcape a little longer than the leaves. The ſegments of theſe are fleſhy oblong, quite entire, or ſometimes but very ſeldom, having an angle or toothlet on the outſide, imbricated, covering the middle of the preceding ſegment, terminated by a whitiſh dagger-point. (In the cultivated plant theſe ſegments are diſtinct or remote from each other.) Calyx calycled; ſcales ovate, the inner ones lanceolate.

Native of the Levant. Introduced in 1770, by Monſ. Richard. It flowers from june to auguſt[b].

4. Leaves ſublyrate, naked, ſcarcely rugged, opaque, ſubciliate: ſegments ſubalternate, ſomewhat toothed, the end one three-lobed and angular. Scapes even, having a pellucid meal ſcattered over them, ſiſtulous, thickening towards the top, bending to one ſide. Calyx oblong, ſqueezed cloſe, hexangular, ſix-leaved or thereabouts; leaflets lanceolate, ſlightly keeled, equal; with as many leaflets on the outſide covering the baſe of the calyx. Seeds crowned with a rugged rim, and an awned down[c].

Native of Sicily, the county of Nice, Villafranca, &c. It is annual, according to Allioni.

5. The firſt root-leaves are ovate, the next lanceolate, the laſt lyrate, acute and ſmooth. Scapes three times as long as the leaves. Calyxes quite ſimple, not imbricated, compoſed of ten lanceolate leaflets. Corolla deep yellow. Seeds four-cornered, crowned with an entire membranaceous rim, and three or four long briſtles beſides. Native of Virginia[d].

6. This is an annual plant, native of Madeira, flowering in june and july. Introduced by Mr. Francis Maſſon in 1778[e].

7. Root annual, ſmall but woody, with a few rigid fibres. Leaves ſpreading in a circle, bluntly oval, tapering into the foot-ſtalk, toothed on the ſides, entire at the baſe and ſummit, when viewed with a glaſs ſlightly hairy, particularly at the margins. Stems ſeveral, ſix to nine inches high, naked, round, ſmooth, reddiſh and wiry at the bottom, green and hollow upwards, gradually ſwelling for ſome diſtance below the calyx, ſometimes ſimple, but oftener with one, ſometimes two branches; theſe are alſo rigid and reddiſh at the baſe, ſwelling upwards, and ſometimes again branched; before the flowers expand nodding, afterwards erect. Outer ſcales of the calyx ſmall, dry and withering; inner lanceolate, very acute. Corolla yellow. Seeds oval, ſtriated, crowded with the remains of the proper calyx[f]. The whole plant is ſmooth and upright. The florets are truncated, and have commonly five teeth; thoſe in the ray are tinged with purple underneath; they amount ſometimes to ſeventy-ſix in number in one flower. The calyx has about eleven ſmaller, and twenty-four larger ſcales. Receptacle naked. At the origin of the branches, and on the branches themſelves, are a few awl-ſhaped ſcales or ſtipules[g].

Native of moſt parts of Europe in paſtures and corn fields in a ſandy ſoil. In Britain not very common. About Hampton Court and in Teddington field; Walthamſtow, Eſſex; near Perſhore in Worceſterſhire; Dorſetſhire; near Norwich; near Gamlingay in Cambridgeſhire; Spratton in Northamptonſhire. About Forfar, and between Dundee and St. Andrew's in Scotland.

Gerarde calls it Male Swines Succorie; Parkinſon, Cluſius his leaſt Hawkeweede, Ray, Small Swines Succory or Hawkweed; Hudſon, Leaſt Hyoſeris or Swine's Succory; Dr. Withering, Small Swines-eye. It flowers in may and june.

8. Root annual. Stems branched, weak, and bending at each joint, whence ſpringe one ſeſſile, ſmooth, oblong, toothed leaf. Flower, yellow, ſmall, nodding; calyx ſmooth, firm, hard, angular, open when the ſeeds are ripe; the central ſeeds have a hard ſeſſile egret, of ſimple duſky hairs or briſtles[h]. Thoſe of the ray have only a rim.

Native of the South of Europe. Cultivated in 1683, by Mr. James Sutherland. It flowers in june[i].

9. This alſo is an annual plant. Villars ſuſpects it to be no more than a variety of the preceding; the calyx is villoſe, and leſs hard. It is a native of the South of Europe, and was introduced in 1773, by Monſ. Richard. It flowers in july and auguſt[k].

10. Root annual, round, fibrous, white within, brown without. Stems ſeveral, half a foot high, ſpreading ſomewhat hiſpid. Leaves oblong, narrower at the baſe, tooth-runcinate, hiſpid; ſtem-leaves alternate at the inſertion of the flowers. Flowers ſolitary, erect, terminating and axillary; peduncles gradually thickening towards the top, ſiſtuous, ſomewhat compreſſed. Common calyx compoſed of near twenty leaflets, with ſome ſhort ſcales at the baſe; when the ſeed is ripe, hiſpid, globular and reddiſh. Proper calyx of each floret very ſhort, ten-parted, permanent. Corollets ſhort, pale yellow, with the apex of the tube villoſe[l]. Receptacle flat, ſmooth, hollow-dotted. Seeds almoſt cylindrical, rugged, ferruginous; the inner ones longer, and almoſt ſtraight; the marginal ones ſhorter, bowed in, half involved in the calycine leaflets, both downy: down of the ray ſhort, compoſed of chaffy, toothletted leaflets, which are connate at the baſe, and almoſt equal, or of three only ſhortly awned; down of the diſk compoſed of ſeveral ſhort awl ſhaped leaflets, and five chaffy ones, ending in a very long toothletted awn[m].

Native of Candia, the county of Nice, and common about Madrid, flowering in may and june; with us in june and july. It was cultivated by Mr. Miller in 1739[n].

Cavanilles is of opinion that Hyoſeris cretica of Scopoli is H. Hedypnois of Linnæus, becauſe he has figured the fruit ſmooth, all the ſeeds with a down, and the flowers three times the ſize as they are in this ſpecies.

Lamarck and Cavanilles refer Hyoſeris minima and foetida to the genus Lapſana, becauſe the ſeeds are naked. Gærtner refers Hyoſeris radiata to Hedypnois: *vol.* 2. *p.* 373. The down of egret being uniform, unequal and ſeſſile. On the contrary he would refer Leontodon hirtum of Linnæus to this genus Hyoſeris. See Apargia hirta.

PROPAGATION AND CULTURE.

Theſe are all hardy plants, except the ſixth, and may eaſily be propagated from ſeeds, either ſown in the ſpring, or left to ſcatter of themſelves. The ſixth requires the protection of a green houſe. They moſtly require a dry ſoil.

HYPECOUM. (*From* ὑπηκοος, *reſono.* Tournefort *of Diſcorides*; Hypecoum *of Pliny.*)

Siliques erect, round, toruloſe.

DESCRIPTIONS, &c.

1. [Root ſimple, ſometimes biſid, long, but annual, having but few fibres. Leaves divided by many inciſures, ſomewhat reſembling thoſe of Fumitory, pale green, with a tinge of grayiſh or glaucous colour, ſpread on the ground. Stems ſeveral, ſlender, ſomewhat compreſſed [a], naked at bottom, but having two or three ſmall leaves at top, of the ſame ſhape and colour with the under ones: from among theſe leaves come out the peduncles, each ſuſtaining one ſmall yellow flower. [The fruit is a capſule ſhaped like a filique or pod, long, bowing, compreſſed and ancipital, jointed with tranſverſe knots, and grooved with longitudinal ſtreaks, many-celled: the cells in a ſingle longitudinal row, and ſcarcely ſeparating ſpontaneouſly. Seeds from ten to twenty, roundiſh, cut off as it were on one ſide, compreſſed like a lens, ſomewhat wrinkled, dotted in relievo, very dark brown, inſerted alternately into the outer and lower angles of the cells [b].

Native of the South of Europe; and cultivated before 1597, by Gerarde [c].] It flowers in june and july, and the ſeeds ripen in auguſt.

2. The ſecond ſort has ſlender ſtalks, which ſtand more erect, and the ſegments of the leaves are longer and much narrower than thoſe of the firſt; the flowers are ſmaller, and come out at the diviſions of the branches. This flowers and ſeeds at the ſame time with the firſt. [The flowers are yellow, like thoſe of greater Celandine, but leſs [d]. Native of the South of France. Cultivated here in 1640 [e]. Gerarde calls the firſt Horned Wild Cumin; and this Codded Wild Cumin.]

3. This has much the appearance of the ſecond ſort in leaf and flower, but the pods grow erect, and are writhed and twiſted about. It flowers and ſeeds at the ſame time with the others. Ammann received the ſeeds from Dauria, and Müller from Iſtria. [The latter cultivated it here before 1759. In Syſtema vegetabilium it is obſerved that the ſtamens appear to be tetradynamous.]

The juice of theſe plants is of a yellow colour, reſembling that of Celandine, and is affirmed to have the ſame effect as opium.

PROPAGATION AND CULTURE.

Theſe plants being all annual are propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, on a bed of light freſh earth, where they are to remain; for they ſeldom ſucceed if tranſplanted. When the plants come up, clear them from weeds, and thin them to the diſtance of ſix or eight inches.

When the ſeeds are ſown in the ſpring, and the ſeaſon proves dry, they will not grow the firſt year; but if the ground be kept clear from weeds, and not otherwiſe diſturbed, the plants will come up the following ſpring. The ſeeds will ſometimes lie even till the third ſpring. It is therefore beſt to ſow them in autumn in a warm border; for theſe will make ſtronger plants, more likely to perfect ſeeds than thoſe ſown in ſpring. The ſeeds, when ſown, ſhould be diveſted of their fungous covering, which adheres ſo cloſe that it prevents their growing till it is decayed. If the ſeeds be permitted to ſcatter, they will frequently come up of themſelves, without any care.

Theſe plants are ſeldom cultivated but by thoſe who are curious in botany; ſince, however, they require little trouble, they may have a place in large gardens for variety; and as they take but little room, they may be intermixed with other ſmall annual plants in large borders, where they will make a pretty appearance.

[HYPELATE. (*So named by Browne, from* ὑπὸ *and* ἐλάτη *a fir-tree.*)
Lin. gen. Schreb. n. 1588. *Browne, jam.* 208. *Swartz prodr.* 61.
Claſſ. 23. 1. Polygamia Monoecia.

GENERIC CHARACTER.

* HERMAPHRODITE FLOWERS.

CAL. *Perianth* five-leaved (ſeldom four-leaved): *leaflets* ovate, concave, ſpreading, deciduous: two leſs than the others.

COR. *Petals* five, ovate, a little leſs than the calyx, deciduous; with the nectariferous umbilicus about the germ.

STAM. *Filaments* eight, ſpreading, round the baſe of the germ, the length of the corolla. *Anthers* ovate-cordate.

PIST. *Germ* globular, ſuperior. *Style* ſhort, upright. *Stigma* bent down, three-fided, three grooved, acute.

PER. *Drupe* pulpy, roundiſh.

SEED. *Nut* oval, very ſmooth, with a ſingle kernel.

* *Male flowers, on the ſame tree, but on a diſtinct panicle.*

CAL. and COR. as in the Hermaphrodite.

Nectary alſo as in that; from the middle of this.

STAM. *Filaments* eight, converging at the baſe, from erect reflex and aſcending, broader at the baſe. *Anthers* ovate-cordate.

PIST. three-cornered rudiment of a germ. *Style* awl-ſhaped, very ſmall.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* five-petalled. *Stigma* bent down, three-cornered. *Drupe* one-ſeeded.

SPECIES.

1. Hypelate trifoliata.
Swartz prodr. 61. *Brown. jam.* 208. 1.
Cytiſus arboreus, foliis obtuſis, petiolis alatis. *Sloan. jam.* 2. 33. *Raii hiſt.* 3. 473.

DESCRIPTIONS, &c.

This ſhrubby tree has ſeveral trunks, each as big as the human leg, ſtraight, eight or nine feet high, covered with a ſmooth cinnamon-coloured bark. The branches riſing upright, are all round beſet with leaves, coming out at intervals of an inch, three always together, at the end of a green common foot-ſtalk, a little foliofe or flat, with extant narrow *ale*, each an inch long, half as broad near the farther end, where broadeſt, and round, beginning narrow, and augmenting to the extremity, of a yellowiſh green colour, very ſmooth, having one middle rib, and ſome tranſverſe ones [a].

Browne obſerves, that it is full of ſlender branches, and furniſhed with many leaves of the ſame texture and grain with thoſe of Lignum-vitæ, but remarkably different both in form and diſpoſition. He had never ſeen the fruit in a perfect ſtate.

Native of Jamaica, where it is very common in the low lands.

HYPERICOIDES. See *Aſcyrum* and *Hypericum.*]

HYPERICUM. (Τριφύλλιον *of Dioſcorides.* Τριφύλλινον, *Nicand. in alexiph.*—Hypericum *of Pliny.*—*From* ὑπὲρ, *ſupra, and* εἰκὼν, *imago Linn.* Androſæmum, *q.* ἀνδρὸς αἷμα, *becauſe it tinges the fingers with red.* Aſcyrum, *q.* ἀσκυρὸν, *not hard, very ſoft.*)

Claſſ. 18. 4. Polyadelphia Polyandria.

Nat. order of *Rotaceæ.—Hyperica*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted; *ſegments* ſubovate, concave, permanent.

COR. *Petals* five, oblong-ovate, obtuſe, ſpreading, wheel-ſhaped, according to the ſun's apparent motion.

STAM. *Filaments* numerous, capillary, united at the baſe in five or three bodies. *Anthers* ſmall.

PIST. *Germ* roundiſh. *Styles* three, (ſometimes one, two or five) ſimple, diſtant, the length of the ſtamens. *Stigmas* ſimple.

PER. *Capſule* roundiſh, with the ſame number of cells as there are ſtyles.

SEEDS very many, oblong.

OBS. Aſcyrum Tourn. *has five ſtyles, with ſimple ſeeds.*

Hypericum T. *has three ſtyles, with a membranaceous pericarp.*

Androſæmum T. *has three ſtyles, with a ſoft coloured pericarp.*

ESSENTIAL CHARACTER.

Cal. five-parted, inferior. *Pet.* five. *Filam.* many, connected at the baſe in three or five bundles. *Capſule* many-ſeeded.

Stamens longer than the corolla, calyxes coloured, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

[These are herbs, ſhrubs or underſhrubs, with cylindrical, ancipital or quadrangular ſtems. Leaves frequently with pellucid dots. Flowers ſometimes in cymes, but more frequently in corymbs, with the peduncles often trichotomous and three-flowered, terminating or axillary alſo [a]. Corolla yellow.

This numerous genus is divided by Linneus into four ſubordinate parts from the number of ſtyles. The predominating number however is three. Juſſieu remarks, that it might be ſplit into ſix genera. 1. Aſcyrum, (one to twelve) with five ſtyles, and a capſule with five cells; to which may be added Aublet's ſpecies from Guiana, t. 311, 312. turgid with a yellow reſinous juice, and hence allied to the Guttiferæ. 2. Hypericum properly ſo called, (14, &c.) with three ſtyles, hnd a three-celled capſule, with the pencils of filaments, ſcarcely united at the baſe. 3. Androſæmum, (13, &c.) with a ſoft pericarp reſembling a berry, almoſt one-celled, turgid with a blood-red juice. This diviſion has three ſtyles, and in other reſpects reſembles that immediately preceding. 4. Elodea of Adanſon, (48, &c.) with three ſtyles and a pericarp of three cells, the filaments united up to the middle, the diſk of the germ glandular, as are alſo the claws of the petals. 5. Knifa of Adanſon, (54, 55.) with two ſtyles, and a two-celled pericarp. 6. Komana of Adanſon, with one ſtyle, or five ſtyles ſo cloſely joined as to ſeem one. (56, 57.)

[a] Juſſieu. gen.

Whatever

Whatever may be thought of theſe diſtinctions, for dividing this natural genus; they will be of conſiderable uſe in diſtinguiſhing the numerous ſpecies.]

1. Warted St. John's-wort riſes with a ſlender ſhrubby ſtalk, in this country, about two feet high, but in its native ſoil it acquires the height of ſeven or eight feet, ſending out ſeveral weak branches of a red-diſh colour, and marked with ſcars where the leaves have fallen off. Leaves ſmall, oval, waved on their edges, and having ſeveral ſmall protuberancies on their under ſide: they ſit cloſe to the branches, half embracing them at the baſe. Flowers terminating, large, bright yellow. Stamens a little ſhorter than the petals. Capſules pyramidal, having a ſtrong ſmell of turpentine, and filled with ſmall brown ſeeds.

[Linnæus obſerves that the ſtems are quadrangular, with glandular dots in racemes ſcattered over them; the leaves flexuoſe with warted glands at the edge; the flowers ſolitary. Mr. Curtis however remarks, that the flowers are not always ſolitary, but frequently form a ſort of corymbus.]

This plant was diſcovered in Majorca by Dr. Thomas Penny, a phyſician of London who ſent it to Lobel and Cluſius, in the year 1580, under the name Myrto-Ciſtus, from the reſemblance of the leaves to Myrtle, and the gummy ſubſtance exuding from the plant as in Ciſtus. From that time the plant ſeems to have been known only from Cluſius, whoſe figure is very indifferent, till about the year 1714, when Mr. Salvadore, an apothecary of Barcelona, went to Majorca in ſearch of plants, found this in great plenty, and ſent dried ſamples of it to England and Holland, ſome of which having ripe ſeeds on them were ſown; and from theſe one plant was raiſed in the Chelſea garden, and another by Boerhaave at Leyden in 1717. From theſe many plants were raiſed by cuttings, and diſtributed to moſt of the curious gardens in Europe. It has a ſucceſſion of flowers great part of the year, which renders it valuable. [Gerarde calls it the Reverende D. Penny his Ciſtus; the title of Reverend is omitted by Johnſon, and therefore I conclude it was a miſtake.]

2. This riſes with an upright herbaceous ſtalk three feet and a half high, ſending out ſeveral ſmall branches at top, which come out oppoſite. Leaves oblong, oppoſite, half-ſtem-claſping. At the end of each branch is produced one pretty large flower, with a blunt calyx. Stamens equal in length with the petals. Styles ſo cloſely joined as to appear but one. Stigmas reflexed.

[Linnæus deſcribes it as ſhrubby, with quadrangular branches. Leaves ſmooth, like thoſe of Roſemary or Lavender. Flowers in a dichotomous terminating corymb, compoſed of three or ſeven flowers. Capſule ovate, the length of the calyx, which is bluntiſh and lanceolate. Styles five, very ſlender.—Reichard affirms that it has only three ſtyles.

Native of North America, where it was found by Bartram, and in Virginia by Kalm. It was cultivated by Miller before 1759.

3. This is an upright branching tree, eighteen feet in height. Leaves oppoſite, petioled, quite entire, rugged, acute, ſhining, marked with black dots, two or three inches in length. Racemes compound, terminating. Petals white, hirſute within, as in Gordonia Laſianthus. Nectareous glands five, ovate, the length of the germ, alternate with the pencils of ſtamens. Filaments five, divided at top into a pencil. Anthers globular. Fruit a berry, with a ſulvous ſtaining juice. Seeds numerous. It ſhould be diſtinguiſhed from Gordonia Laſianthus, which has alſo a hirſute corolla, but the leaves in this are oppoſite and quite entire.

Native of Cayenne [b].

4. This is a ſhrub three fathoms in height, upright and brachiate; with quadrangular branches. Leaves oppoſite, acuminate, quite entire, ſomewhat veined, ſhining, hoary underneath, a ſpan in length; on ſhort, round petioles, channelled above. Flowers terminating, panicled, on ſhort pedicels. Calycine leaflets five, ovate, acute, ſcarioſe at the edge, ſpreading. Filaments in five ſets, the baſe of which is a flat, upright, pencil-form column. Anthers roundiſh. Germ ovate, five-cornered. Styles five, upright, permanent. Fruit an ovate acuminate berry, ſlightly five-cornered, five-celled. Seeds numerous oblong, in a double row. The whole plant abounds in a viſcid tough ſaffron-coloured juice. It has diſtinct nectaries, like the preceding, alternate with the ſets of ſtamens, from which it is doubtful whether it be diſtinct [c].—Native of Mexico, and Braſil.]

5. The ſtalks of the large-flowering Tutſan are ſlender and incline downwards. Leaves ſmooth, placed in pairs. Flowers very large, bright yellow. Capſules pyramidal.

[Stems evergreen, branched, red, quadrangular. Leaves ovate-oblong, of a firm conſiſtence, blunt, quite entire, ſubſeſſile, three or four times as long as the internodes. Flowers terminating, peduncled, ſolitary. Calyx membranaceous, with ovate blunt leaflets, the length of the germ, twice as large in the ripe fruit. Corolla twice as long as the calyx. Stamens yellow, ſhorter than the corolla. Germ red. It has the habit of H. Androſæmum [d].

To this we may add from Ray that the ſtem is not more than a ſpan high, that the petals are bowed or arched inwards, and that the capſules are three times as large as any of the other ſpecies.

The ſtems are only tinged with red in places. The leaves on the young ſhoots are of a beautiful light green, of a regular ovate form, and half embrace the ſtem, on the older branches they are of a very dark green and glaucous on the back, rather ſubſeſſile, and frequently drawn out more in length. The flowering peduncle is upright, little more than half an inch in length, and has a pair of ovate bractes at its baſe hollowed like the bowl of a ſpoon: the fruiting peduncle is near an inch long, and arches downwards, ſo that the capſule hangs below the horizontal line; it is accompanied with the calyx at the baſe and the ſtyles at the top, and loſes its red colour.

Native of the country near Conſtantinople. Introduced in 1676, by Sir George Wheler, Bart. It flowers from june to ſeptember [e]: and ſome flowers ſtill remain this 28th day of october 1796, on which I am writing this article.

It is very hardy, and increaſes much by the creeping roots. Like the Periwinkle, it is a plant well adapted to cover a bank, or bare ſpots under trees, where few other plants will thrive [f].

6. The native country of this is not known. It was cultivated in 1764, by Mr. James Gordon; and flowers in july and auguſt [g].

7. Stem arboreſcent, with a ſmooth aſh-coloured bark. Branches ſcattered, round, ſmooth. Leaves ſeſſile, two or three inches long, ſcattered, coriaceous, broad-lanceolate, narrower at the baſe, obſcurely veined, very ſmooth. Peduncles one-flowered, an inch in length, angular, with three ſmall leaflets towards the top, of the ſame form with the branch-leaves. Calycine leaflets coriaceous, rounded, ſmooth, one-third of the length of the corolla, even. Petals entire. Germ five-cornered, ovate, acuminate, ſmooth. Styles reflex.—Found in the Eaſt Indies by Koenig [h].

8. This is a glaucous plant. Stem a foot high and more, upright, ſingle or branched; branches alternate, flexuoſe, one-flowered. Leaves thickiſh, with impreſſed dots on both ſides. Flowers panicled, on the branches ſolitary, terminating. Calyx ſcarcely divided beyond the middle; ſegments ovate, acuminate, ſurrounded at the baſe with leafy ſcales. Petals ovate, much more produced on one ſide, concave, coriaceous, with ſcales on each ſide at the claw, embracing the alternate petals. Filaments united at the baſe into five or more ſets. Anthers orbiculate, peltate. Styles the length of the ſtamens.—Found by Billardiere in dry ſpots, near the deſert of Syria [i].

9. This is a ſhrub with an aſh-coloured bark. Branches even, round; on each branchlet two pairs of leaves, the lower pair ſmaller. Leaves oppoſite, petioled, acuminate, even, quite entire. Peduncle op-

[a] Linn. [b] Linn. and Jacq. [c] Ibid. [d] Hort. kew. [e] Hort. kew. [f] Curtis. [g] Vahl. [h] Willard.

poſite,

poſite, by the ſide of the upper pair of leaves, ſpreading, the length of the leaf, bifid or trifid, many-flowered, ſubumbellled. Calycine ſegments lanceolate. Petals upright, ſpreading above the middle. Nectary of five ovate glands. Filaments ſhort, united at the baſe in five ſets, faſtened to the bottom of the petals, and ſhorter than they are. Germ ovate, five-cornered. Found in Guinea by Andr. Berlin[b].

10. This is a tree with the appearance of Bay. Leaves oppoſite, petioled, acute, quite entire, ſmooth, like thoſe of Bay, with tranſverſe veins. Panicle terminating, brachiate, the length of the leaf. Petals obovate, ſtraighter on one ſide, the length of the calyx. Five minute nectareous ſcales alternate with the ſtamens. Germ the length of the calyx. Berry ovate, with five ſwellings, and five cells. The tree abounds with a ſaffron-coloured viſcid juice[i].

Loureiro has deſcribed a plant which he found near Canton in China under this name, but differing very much in the deſcription. The ſtem is ſhrubby, manifold, three feet high, angular, diffuſed. Leaves broad-lanceolate, quite entire, ſcarcely tomentoſe, oppoſite, petioled. Flowers reddiſh-yellow, axillary and terminating, on few-flowered peduncles. Stamens in three elevated ſets, with as many large alternate glands at the baſe. Styles three. Capſule three-celled.

According to Linneus, it was found in New Granada by Mutis.

11. Branches round, purpliſh, flexuoſe-aſcending, ſpreading, weak, ſmooth. Leaves oppoſite, ſeſſile, acute, ferruginous underneath, horizontal, an inch long, double the length of the internodes. Flowers ſolitary at the ends of the branchlets. Calycine ſegments ovate, very blunt, ſmooth, half the length of the corolla, which is yellow, but reddiſh underneath. It differs from H. calycinum in having ſmaller leaves, not coriaceous, rolled back at the edge, in having the ſtem fruteſcent only at the baſe; and the branches looſe and ſpreading.—Native of Japan[m].

12. Stem a cubit and half high, round, ſmooth, ruſeſcent. Leaves pale green, paler underneath, an inch long and half an inch wide, roundiſh, oppoſite. Flowers terminating; calyx green, corolla pale yellow, five times as large as in common Hypericum; petals an inch long. Found in the Pyrenees by Burſer[k].—Native alſo of Siberia and Canada, according to Linneus, who remarks that the leaves are acute.

13. Root perennial, thick, woody, of a reddiſh colour, ſending out very long fibres. Stems ſuffruticoſe or underſhrubby, ancipital two-edged or ſlightly winged on oppoſite ſides, two feet high and more, branched towards the top, of a reddiſh colour and ſmooth. Branches brachiate or decuſſated, ſpreading. Leaves oppoſite, ſeſſile, ovate, entire, ſmooth, dark green, glaucous on the under ſide, netted with numerous projecting veins and nerves, which become through age ferruginous. On the ſtem they are two inches long, and an inch and a half broad at the baſe; thoſe on the branches are ſmaller, of different ſizes, and ſome of them approaching to lanceolate. Flowers ſmall for the ſize of the plant, diſpoſed in a cyme. Peduncles round, ſmooth, uſually two or three-flowered, but ſometimes one-flowered. Calyx deeply divided; ſegments ovate, ſlightly nerved, unequal, the three outer ſegments being commonly much larger than the two inner ones; they are upright and longer than the germ, but that advances above them as it ripens into a fruit, and then the ſegments of the calyx turn back to the peduncle. Petals ovate, obtuſe, nearly equal, a little longer than the calyx, ſpreading, concave, the tips bending a little inward, deciduous. Filaments more than forty, longer than the corolla. Anthers ſmall and roundiſh. Germ roundiſh, ſhining, yellowiſh. Styles the length of the germ, upright, permanent. Fruit an ovate capſule, aſſuming the appearance of a berry; at firſt yellowiſh green, then red or browniſh purple, and laſtly almoſt black when ripe[n].

The juice expreſſed from the leaves is claret-coloured. The leaves were formerly applied to freſh wounds, and hence the French name of *La toute ſeine*, and our Engliſh one of *Tutſan*. It is alſo called *Park-leaves*, from its being frequently found in parks. In Italian, Spaniſh, and Portugueze it is *Androſemo*; in German *Konradskraut*, or *ſtandenartige Johanniskraut*; in Dutch *Groobladig Hypericum*, or *Manſbloed*. It flowers from july to ſeptember.

Native of the ſouthern parts of Europe and Britain, in woods and moiſt hedges. With us, near London it is found about Hampſtead and Highgate; on Bacher heath and Harefield, Middleſex; in the Oak of Honour wood near Peckham Rye, and in ſeveral parts of Norwood, but ſparingly. In many parts of England it is more common; as in the Duke of Bridgewater's woods at Aſheridge, and near Berkhampſtead, Hertfordſhire; North Walſham and Field Dalling, Norfolk; in lanes at the foot of Malvern-hill, Worceſterſhire, and between Worceſter and Tewkeſbury; in Shotover plantations, Stokenchurch and Nettlebed woods, Oxfordſhire; near Pengwarry in Cornwall; rocky woods in Weſtmoreland; King's Cliff in Northamptonſhire. In Scotland alſo, as in the woods at Inverary, and at Loch-Ranſa, in the iſle of Arran.]

14. This riſes with many upright woody ſtalks about a foot high. Leaves ſmall, lanceolate, ſeſſile, oppoſite. Flowers terminating, three or four together. Petals oblong, bright yellow. Filaments unequal, ſome longer others ſhorter than the petals. Germ ovate. Styles longer than the ſtamens. It flowers from july to ſeptember.

[It differs from H. calycinum, not only in having three ſtyles, and the ſegments of the calyx acute, but in having higher ſtalks, ſmaller leaves reſembling thoſe of common Hypericum, only ſtill leſs, and the capſule round like that of Androſæmum, with three cells, whereas that is oblong with five cells[o].

Native of the Levant, and found by Sir George Wheler on mount Olympus.—Cultivated in 1706 in the botanic garden at Chelſea[p].

Loureiro deſcribes it as a tree ten feet high with ſpreading branches. Leaves ovate-lanceolate, quite entire, ſmooth, oppoſite. Flowers on hoary peduncles, one or two together, lateral and terminating. Calyxes acute. Petals quite entire. Stamens in three ſets. Capſule three-celled.—Native of Cochinchina, and of China about Canton.

15. Native of the Azores, where it was found by Mr. Francis Maſſon. Introduced in 1778. It flowers in auguſt.

16. Native of Madeira. Introduced in 1779 by Mr. Francis Maſſon. It flowers in auguſt[r].

17. Branches quadrangular at top, ſmooth with a purpliſh bark. Leaves petioled, two inches long and more, a little acuminate, veinleſs, coriaceous, quite entire, with a glaucous dew ſcattered over the upper ſurface. Raceme terminating, compound, a ſpan long. Peduncles compreſſed. Pedicels four or five at each joint of the partial peduncle, ſhort. Calyx five-leaved; leaflets ovate, ſmooth, quite entire, even, naked. Petals of the ſame length and form with the calyx. Filaments in three ſets, connected almoſt to the top; the ſets are ſquarroſe on the outſide with the diſtinct ſpreading tips of the filaments, which are covered with numerous anthers, and are even within. Germ three-cornered, ſmooth, ovate. It has the habit of H. guineenſe, but differs in the number of piſtils and in the inflorescence.

Native of the Eaſt Indies[s].

18. Stem upright, ſimple at bottom, ſmooth, as is the whole plant, four-cornered by means of a line running down from each ſide of the baſe of the leaf. Leaves ſeſſile, veinleſs, paler underneath, the lower ones narrower, the upper ones ovate-attenuated, without glands or dots. Peduncles terminating and at the diviſions, filiform, ſolitary, one-flowered, an inch long. Calycine leaflets lanceolate, quite entire, without glands, the length of the corolla. Stamens as long as the corolla.—Native of New Caledonia in the South Seas[t].

19. This is a ſmall tree or ſhrub with alternate

[b] Linn. ſuppl. [i] Ibid. [m] Thunberg. [n] Bauh. prodr. [o] Curtis, With. Lightf. [p] Ray. [r] Hort. kew. [s] Ibid. [t] Vahl. [u] Ibid.

branches. Leaves oppoſite, petioled, acute, naked, two inches long. Pedunclesaxillary, ſolitary, bifid; and terminating many flowered. Calycine ſegments roundiſh, lying over each other on one ſide, coriaceous. Petals obovate, ſtriated, longer than the calyx. Filaments three, broad, divided into many threads which are gradually higher from the outſide, the upper ones barren, the outer anther-bearing. Germ three-cornered. Styles broadiſh.—Brought from China by Bladh[a].

20. This is a middle-ſized tree, about ſixteen feet high, with aſcending branches, divided into very many duſky-red branchlets. Leaves lanceolate-ovate, blunt, quite entire, ſmooth, ſmall, oppoſite. Peduncles five-flowered or thereabouts, axillary. Calycine ſegments acute, entire. Petals ſcarlet, ovate-oblong, entire, ſpreading. Nectary of three large, reclining glands. Stamens about one hundred, in three ſets. Capſule ovate, coloured, three-celled, filled with many oblong, flattiſh ſeeds.—Native of Cochinchina, in woods.

The wood of this tree is red, heavy, hard and tough; and is uſed for making oars and yards of veſſels. The juice of the flowers dyes of a golden colour[b].

21. Stature and ſtamens of Gordonia Laſianthus. Stem four-cornered, blunt. Stipules none. Leaves like thoſe of Lemon, petioled, acute, obſcurely tomentoſe underneath. Corymb brachiate. Sets of ſtamens oblong, very handſome.—Native of Braſil[c].

Here we have inadvertently two different plants under the ſame name; this and n. 10.]

22. Canary St. John's-wort riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing into branches at top. Leaves oblong, ſet by pairs cloſe to the branches, having a ſtrong odour, but leſs than thoſe of the hircinum. Flowers terminating in cluſters, very like thoſe of hircinum. Stamens longer than the petals.—Native of the Canary iſlands. [Cultivated in 1699, by the Dutcheſs of Beaufort. It flowers from july to ſeptember.

23. Native of North America. Cultivated in 1762 by Mr. James Gordon. It flowers in july and auguſt[d].]

24. This riſes with ſhrubby ſtalks about three feet high, ſending out ſmall oppoſite branches at each joint. Leaves oblong, ovate, placed by pairs, ſeſſile, and having a rank goatiſh ſmell. Flowers in terminating bunches. Petals oval. Stamens longer than the petals, and ſtyles longer than the ſtamens. Capſule ovate. [Native of the South of Europe. Cultivated here in 1640. It flowers from july to ſeptember.

There are two varieties of it in the gardens, one larger, which is the common one; the other ſmaller[e].

25. This is a ſhrub a ſpan high, very much branched, and brachiate; the branchlets are compreſſed. Leaves like thoſe of knot-graſs (Polygonum), ovate, very ſmall, acuminate, veinleſs, ſeſſile, longer than the joints of the branches. Flowers commonly in pairs on the branchlets. A nectariferous oblong ſcalelet, within the claw of each petal. It has the appearance of a ſand plant, and is a native of Egypt[f]. Introduced in 1787, by Monſ. Thouin[g].

26. Roots in old plants hard, woody, and more than half a foot in length; in young plants a tuft of yelloviſh fibres three or four inches long. Stems from ſix inches to a foot in height, ſome upright, others aſcending, pale green, a line in thickneſs, with a ſmall wing deſcending from one leaf to another. Leaves oppoſite, an inch or fifteen lines in length, and two lines in breadth, pale green, crenate like Ptarmica or Sneezewort, ſeſſile, with two very pointed earlets at bottom, two lines long, cut more deeply than the reſt of the leaf. From the upper axils ſpring little branches, with leaves like the others, but ſhorter and wider. Theſe flowering-branches form a cyme like that of common St John's-wort. Petals eight or nine lines long, and three lines wide, round at top. Stamens ſhorter than the petals. Calyx three lines long, toothed on the edge. Capſule ruſſet-coloured, three lines long, five-celled. Seeds brown. The whole plant has a reſinous ſmell. It varies much in ſize, as does alſo the flower, the petals being ſometimes ten lines in length. The leaves are bitter and a little viſcid.—Native of the Levant[h].

27. Stems ſhrubby, when old wrinkled by the falling of the bark, herbaceous, rufeſcent, having raiſed dots ſcattered over them, whence they are rugged. Leaves oppoſite, oval-lanceolate, even, quite entire. Flowers ſmall, in terminating corymbs. The ſcars or raiſed dots on the ſtem are longer than in H. balearicum, the leaves have no apparent glands, and there being only three ſtyles in the flowers, this is diſtinct from that.—Native of Arabia and Barbary.

28. Root perennial. Stems at bottom woody, round, filiform, creeping; putting out roots at the joints. Leaves quite entire, oppoſite, rather crowded. Flowers terminating, three, the middle one ſeſſile. Calyx and bractes having brown dots ſcattered along the edge, but not ſerrate.

Native of the Levant, where it was found by Tournefort. Haſſelquiſt alſo diſcovered this in Paleſtine, and the preceding in Arabia[i].

29. Stems ſtraight, purpliſh. Leaves commonly revolute, whence they appear narrow like thoſe of Roſemary. There are very many primordial leaflets of the branchlets from the axils. Panicle ſmall, terminating. Flowers of the firſt and ſecond dichotomy ſeſſile; the reſt terminating, pedunculed; ſeldom more than ſeven. Stamens not longer than the petals.

Native of North America[k]. Cultivated in 1758 by Mr. Miller. It flowers from june to auguſt[l].

30. Native of Spain, where it was found by Tournefort, and of Portugal.

31. This has the appearance of Leſſer Centaury. Stems herbaceous, round, branched, ſmooth. Leaves linear or ſublanceolate, quite entire, ſmooth. Panicle dichotomous, with pedicelled flowers, which are very ſmall, the ſize of thoſe of Spurge. Pericarp twice as long as the calyx, conical, red.

Native of North America. Kalm obſerved it in Canada[m].—Introduced in 1770 by Samuel Martin, M. D. It flowers from july to ſeptember[n].

32. Stem upright, as it were ſhrubby. Leaves cordate-ovate, with pellucid dots, an inch and half long. Petals pale red. Filaments nine, connate in three ſets. Nectaries three, alternate with the ſtamens, obtuſe, thick, gibbous without, concave within.

Native of North America[o]. It was found by Miſs Colden, daughter of the Hon. Cadwallader Colden, in 1753, and ſhe named it Gardenia; it was alſo found the year following by Dr. Garden, about a mile from New-York. It is deſcribed by both, in the firſt article of the ſecond volume of Eſſays and Obſervations Phyſical and Literary, read before a ſociety in Edinburgh, and publiſhed by them in 1756, octavo.

33. Stems a foot high, ſimple, rugged with warts from the fallen leaves, perennial. Leaves ſeſſile, oppoſite, blunt, veinleſs, even. Corymb terminating, dichotomous, ſeſſile, not longer than the leaves. Petals linear.—Found by Mutis in New Granada[p].

34. Native of North America, where it was found by Samuel Martin, M. D. Introduced in 1772. It flowers in july[q].

35. This is a large ſhrub with divaricating branches, the laſt leafy and tomentoſe. Leaves quite entire, incumbent, perforated, black-dotted at the edge. Panicle rounded. Bractes and calyxes awl-ſhaped[r].

Native of the iſland of Teneriffe. Introduced in 1788, by Mr. Francis Maſſon. It flowers moſt part of the ſummer[s].

36. Square-ſtalked St. John's-wort is ſufficiently diſtinguiſhed from the other ſpecies by that circumſtance which has given occaſion to the trivial name.

The root is perennial, ſomewhat creeping and fibrous. Stems from a foot to eighteen inches in height, upright, branched, ſmooth, reddiſh, ſquare from having

[a] Retz. [b] Loureiro. [c] Linn. ſpec. [d] Hort. kew. [e] Ibid. [f] Linn. ſpec. [g] Hort. kew.

[o] Linn. mant. [p] Linn. ſuppl. [q] Hort. kew. [r] Linn. ſuppl. [s] Hort. kew.

four little membranes or wings running down them. Branches decuſſately oppoſite. Leaves blunt, ſmooth, deep green but paler underneath, ſtrongly marked with ſeven or nine ribs, having a net-work of veins, with tranſparent glands in the interſtices, but not very numerous; diſcernible when viewed with a glaſs in a ſtrong light; the edge, eſpecially on the under ſide, dotted with black glands: the lower ones ſeſſile, oppoſite; the upper growing together. Flowers ſmall, terminating in cloſe panicles: branchlets deep red or blood colour: peduncles very ſhort: bractes ſubulate, in pairs. Calycine ſegments deeply divided, lanceolate ſpreading, ribbed, entire except at the end where they are ſometimes a little toothed; they have no glands. Petals finely grooved, concave, marked with lines and dots, filled with a purple liquor, which ſtains paper with a muddy purple permanent ſtain. Filaments ſcarcely divided into ſets or bundles. Anthers roundiſh, yellow, having a black gland between the lobes. Germ obovate. Styles ſpreading, awl-ſhaped, yellow. Stigmas very ſmall, purple. Capſule brown. Seeds oblong, ſomewhat ſhining [5].

Native of moſt parts of Europe, in moiſt hedges, ſhady places, wet meadows, by rivulets and in bogs; flowering in july.

37. Root perennial, woody, brown. The whole plant is ſprinkled over with ſmall black glands, and is quite free from hairs. Stems ſeveral, about two feet high, woody, upright, ſmooth, round or nearly ſo, alternately two-edged, much branched. Branches oppoſite, nearly upright, two-edged. Leaves decuſſately oppoſite, ſeſſile, oblong-ovate, yelloviſh green, with ſeven or five ſemitranſparent lines, and ſeveral black dots near the edges on the under ſide; the ſemitranſparent dots numerous. Peduncles from the axils of the upper leaves, two-edged, ſupporting many flowers in a buſhy panicle. Calycine ſegments lanceolate, acuminate, ſtriated, entire, without glands, about half the length of the petals. Petals ſtriated, ſet near the edges, and ſometimes over the whole ſurface with very dark-purple glands, one of the ſides entire, the other irregularly notched. Filaments thirty or more, ſcarcely united into three ſets or bundles. Anthers two-celled, each of the cells roundiſh, with a ſmall, globular, black gland between them. Germ ſubovate. Style divaricating. Stigmas dark red or crimſon [6].

Common in woods, thickets, hedges and dry banks, flowering from july to ſeptember.

Although in the preſent practice St. John's-wort is not much regarded, yet its ſenſible qualities, and the repeated teſtimonies of its virtues, entitle it, as Dr. Cullen obſerves, to farther trials. To the taſte it is aſtringent and bitter, and its effects ſeem to be chiefly diuretic. From poſſeſſing properties which have been generally called balſamic, it has been uſed as a vulnerary in external wounds and internal hæmorrhages, for the former purpoſe the tops of the plant with the flowers are infuſed in oil, and for the latter an infuſion of the plant is made in the manner of tea. It has likewiſe been given in ulcerations of the kidnies, and has even been ſuppoſed to poſſeſs virtues as a febrifuge. The leaves given in ſubſtance are ſaid to deſtroy worms. The ſemitranſparent dots on the leaves are the receptacles of an eſſential oil. The flowers tinge ſpirits and oils of a fine purple colour, which is probably derived from the little glands upon the anthers and edges of the petals. The dried plant boiled with alum dyes wool of a yellow colour.

The common people in France and Germany gather it with great ceremony on St. John's day, and hang it in their windows, as a charm againſt ſtorm, thunder, and evil ſpirits; miſtaking the meaning of ſome medical writers, who have fancifully given this plant the name of *Fuga Dæmonum*, from a ſuppoſition that it was good in maniacal and hypochondriacal diſorders. In Scotland alſo it is carried about as a charm againſt witchcraft and enchantment; and they fancy it cures ropy milk, which they ſuppoſe to be under ſome malignant influence, by milking afreſh upon the herb. Kine, goats, and ſheep eat it, but horſes and ſwine refuſe it [7].

38. Stems ſeveral from two to three feet high, upright, ſprinkled with black dots. Leaves large, embracing the ſtem, ovate, very thin and ſkinny at the edge, with black dots underneath. Claycine leaflets very blunt, yellow green, marked with ſhort black lines. Petals large, very entire, yellow, with black lines above, and a few black dots on the edge underneath [8].

In habit, ſize, and colour it nearly agrees with perforatum, but differs eſſentially in having no pellucid dots apparent on the leaves, and in the calycine leaflets being elliptical and obtuſe. The latter indeed, and even the bractes, are ſprinkled with pellucid dots and lines; and the petals as well as the edges of the leaves are marked with opaque purple as in that; but the ſtem of this is in the upper part almoſt quadrangular; and it may be known even before it comes out of the ground, by the much more vivid red of the young ſhoots. It is not, as Leers ſuſpects, the ſame with H. perfoliatum of Linneus.

Native of Germany, Dauphiné, and England; probably of other countries, but unnoticed. Firſt diſcovered in England in july 1797, by Dr. John Steward of Worceſter, growing plentifully about Sapey in that county, and aſcertained by the Rev. Mr. Douglas to be H. dubium of Leers. Luton, Bedfordſhire, Mr. Vaux. Dr. Smith found it in auguſt 1795 about Col. Johnes's at Hafod, Cardiganſhire, and in Mr. Knight's woods at Downton Caſtle, near Ludlow. It flowers in july and auguſt [9].

39. Root perennial, yelloviſh, fibrous. Stems numerous, about half a foot in length, procumbent, round or ſomewhat flatted, ſcarce preceptibly two-edged, ſmooth, reddiſh, branched at top. Leaves oppoſite, oblong-ovate, obtuſe, entire, dotted on the edge with black, with ſemitranſparent dots on the ſurface not diſtinguiſhable but with a glaſs and a ſtrong light. Peduncles axillary and terminating, ſolitary or ſometimes in pairs. Bractes none. Calycine ſegments large, unequal, ovate-oblong, the edge turned back and ſerrate as it were with dark-purple glands, terminating in a red point. Petals oblong, blunt at the end, a little longer than the calyx, dotted on the edge with glands, having a tinge of red on the outſide. Filaments ſeldom more than twenty, in three diſtinct ſets, five or ſix in each. Anthers very ſmall, without glands. Germ roundiſh. Styles ſimple, ſpreading, the length of the ſtamens. Stigmas ſometimes tinged with red. Capſule oblong-ovate, membranaceous, of a very bright red colour before it is ripe.

It is the leaſt of our wild Hypericums, ſcarcely inferior to any in beauty and delicacy; and is not unfrequent in gravelly paſtures, in fields that have long lain untilled, on heaths, eſpecially where the ſoil is moiſt and clayed, and ſometimes in woods: flowering from june to auguſt.

It varies with leaves growing by threes. Scopoli fancies it, but ſurely without grounds, to be a monſtrous variety of H. perforatum [10].

40. Leaves very minute, half ſtem-claſping, curled at the baſe, whence the trivial name.—Native of Calabria, Sicily, and Greece [11].

41. Stem next the root woody, very ſmooth and even, ſlender, quite ſimple except that it is ſometimes branched at the baſe; the branches a foot long, nearly as high as the ſtem. Leaves ſeſſile, remote, revolute. Peduncles at top, filiform, few, ſpreading, oppoſite, commonly three-flowered. Calycine leaflets lanceolate, with a few briſtle-ſhaped toothlets glandular at the tip. Corollas ſmall, a little longer than the calyx. Filaments ſhorter than the petals.—Found by Vahl on heaths near Bayonne and in Navarre [12].

42. Stem upright, round, ſmooth, about eighteen inches high, very little branched and naked for a conſiderable diſtance under the flowers. Leaves few, in pairs, ſeſſile, ovate, the upper ones ovate-lanceolate, with ſeven ribs, and a net-work of veins, the edges ſet with black dots: the upper leaves have numerous, minute,

[5] Curtis, Withering, Woodw. Mſs.
[6] Curtis, Withering, Lightfoot.
[7] Curtis, With. Lightf. [8] Leers. [9] Engl. Bot.
[10] Curtis, With. Lightf. [11] Linn. mant. [12] Vahl.

circular,

circular, transparent dots, visible to the naked eye: but the lowermoſt are dotted only towards the baſe. Flowers in ſhort, branched, terminating or axillary panicles, few together. Bractes, peduncles, and calyxes beſet with ſtrong hairs, each terminated by a black gland. Calyx divided almoſt to the baſe, into lanceolate, pointed ſegments[a]. Petals ſometimes dotted towards the top. Stamens in three ſets. Anthers with a black ſpot or glandule near the baſe[a].

Native of many parts of Europe, in woods and thickets in high ſituations. In Britain, in Charlton wood, Kent; and near Croydon in Surry. Bath hills near Bungay, Suffolk. Stokenchurch, Henley and Maple-Durham, Oxfordſhire. Perſhore and Bredonhill, Worceſterſhire. Frequent in the Weſt of England. In Angleſea, Wales. Near Ingleton, Carrmel-weil, and Furneſs Fells in the North, and in Scotland, but not common.

43. Root perennial. Stem upright, ſimple, ſmooth, round, about a foot high, tinged with purple. Leaves oblong-lanceolate, ſeſſile, blunt, very ſmooth, entire; theſe with the calyx and petals have black dots ſcattered over them on both ſides. Flowers terminating, few, without ſmell. Calycine leaflets lanceolate, acuminate, green, with long glandular ſoft hairs about the edge. Petals obovate, very blunt, flat, ſtriated, very minutely, ſharply and unequally ſerrate at top, ſome of the ſerratures being terminated by a hair. Filaments, anthers, and ſtyles yellow as well as the corolla. Germ ovate, ſmooth, pale yellow. Stigmas browniſh. Capſule ovate, brown, ſmooth, acuminate, with a glaſs appearing to have numerous pellucid glands ſcattered over it. Seeds yellowiſh.

Native of Auſtria, where it was found by Mygind and Boujart; in paſtures by wood ſides, flowering in june, and perfecting ſeeds in july and auguſt[b].

44. Branches obſcurely four-cornered, ſmooth, dichotomous. Leaves ſeſſile, ſmooth, nerved above, marked with very fine lines along the nerves, dotted on both ſides, ſharp at both ends. Peduncles from the extreme axils, three-flowered; ſolitary in the diviſions. Calyx half the length of the corolla, with brown glands at the edge. Corolla pale yellow with brown dots[c].

Native of Madeira. Mr. Francis Maſſon. Introduced in 1777. It flowers from may to auguſt[d].

45. Root perennial, fibrous; fibres brown, rigid, ſomewhat woody. Stems a foot and half to three feet high, upright, ſolid, reddiſh, round, hairy or downy, generally ſimple but ſometimes branched, much leſs ſo however than common St. John's-wort. Leaves decuſſately oppoſite, oblong, obtuſe, ſeſſile, hoary on each ſide, ſeven-ribbed, minute tranſparent dots all over the ſurface, edge finely ciliated. Thoſe of the ſtem are ovate, broader than in H. perforatum; thoſe of the branches are lanceolate. Sometimes the larger leaves have nine ribs. Rudiments of branches conſiſting of four leaves forming a croſs are generally obſerved in the axils of the leaves; theſe however are ſometimes wanting, and ſometimes are drawn out into branches. Flowers terminating, in an oblong panicle forming a kind of ſpike. The floral leaves have glandular ſerratures at the edges. Calycine ſegments lanceolate, with two grooves, and about twelve ſerratures at the edge, each tip with a gland. Petals oblong-ovate, blunt, ſpreading, with ſix or eight ribs, and a few black glands at the end. Stamens about twenty-four (twenty to thirty), obſcurely divided into three bundles, very fine, ſtraight, yellow, ſhorter than the corolla. Anthers roundiſh, double, without glands. Germ ovate. Styles ſpreading, the length of the ſtamens, yellow turning blackiſh by age. Stigmas crimſon.

It differs from common St. John's-wort in being taller, having the ſtem perfectly round and hoary, and the edge of the calyx beſet with black glands. It is alſo more apt to grow in woods and coppices, though it is frequently met with in hedges[e]. Linneus ſays, that the flowers cloſe in the night, which thoſe of H. perforatum do not. It flowers from june to auguſt.

46. Stem round. Leaves ſeſſile. Flowers in terminating, biſid racemes. Stamens in three ſets or bundles[f].

Native of the South of Europe. Introduced in 1772, by Monſ. Richard. It flowers from july to ſeptember[g]. Ray obſerved it about Montpellier, and in the inſland of Malta, where water had ſtagnated during winter.

47. This is a native of Italy, and was introduced in 1785 by Mr. John Græfer. It flowers in may and june[h].

48. Stems round, and nearly proſtrate among wet moſs and graſs, throwing out long fibrous perennial roots from the firſt three or four joints; its ſubſtance is ſpongy, and its upper part downy. Flowering branches aſcending, five or ſix inches high. Leaves oppoſite, covering the ſtem, almoſt orbicular, blunt ſometimes emarginate, entire, with five or ſeven ribs or nerves, clothed eſpecially on the back with down compoſed of fine ſhort jointed hairs; the dots on them are not viſible but with a glaſs and held againſt a ſtrong light. The panicle, terminating at firſt, becomes lateral by the protruſion of the ſtem beyond it, and is dichotomous, rarely producing more than from five to ten flowers, which appear in july and auguſt, and ſeldom expand except in bright ſunſhine. Floral leaves oval-lanceolate, minute, reddiſh, edged with red glands, a pair beneath each diviſion. Calyx divided about half way, fringed alſo with red glands, about one-fourth of the length of the corolla. Petals yellow or reddiſh yellow, twiſted ſpirally or ſometimes merely folded up, marked with eight greeniſh lines or ribs, and having three ſmall greeniſh glands on the inner ſide of the claws at the baſe of the germ. Stamens in three ſets, divided about half way down into from three to five filaments.

This, as Linneus obſerves, is very nearly related to his H. tomentoſum; which however differs from elodes in having oblong leaves, the veins of which ſpring from the midrib, and not from the baſe, a much larger and more compound panicle, the calyx and ſtamens more deeply divided, the former bearing black or purple glands.

Beſides England, this ſpecies has not been obſerved as a native, except in the northern part of France. With us it is not uncommon in bogs; as on Hayes common in Kent, Derſingham moor near Lynn[i], and other bogs in Norfolk, Gamlingay bogs in Cambridgeſhire, Birmingham heath, in Cornwall, &c.

49. The whole plant is ſmooth. Stems from one to two feet high, upright, round, often red, thinly branched, the joints remote: branches oppoſite, ſhort, ſlender and like the ſtem. Leaves in diſtant pairs, triangularly-cordate or obtuſely ovate, ſhining, embracing, nearly horizontal, deep green above, glaucous beneath, with numerous ſemitranſparent dots, particularly near the edge and top, more ſolid to the touch than in the other ſpecies, and frequently of a bright red colour towards the bottom; thoſe on the branches three times ſmaller than the ſtem-leaves, and thoſe on the peduncles lanceolate. Flowering branches or peduncles round, ſlender, axillary, with from one to three flowers at top. Bractes none. Calyx very ſhort, deeply divided; ſegments ovate, ſtriated, ſerrated, and edged with little glands of a blackiſh red colour. Petals oblong-ovate, ſlightly ſtriated; on the under ſide tinged with bright orange, ſlightly ſerrated, and edged with the ſame dark-coloured glands. Filaments in three ſets, from twelve to eighteen in each, ſhining, yellow. Anthers roundiſh, two-celled, with bright ſcarlet pollen. Germ ovate. Styles the length of the germ, ſpreading. Stigmas ſmall, roundiſh. Capſule ſomewhat conical, brown. Seeds oblong, brown[k].

Native of moſt parts of Europe in woods, on heaths, banks and in hedges, eſpecially in a clayey ſoil: flowering in june and july.

[a] Woodw. Mſs. Stokes in Withe. [b] Lightfoot. [c] Jacquin. [d] Vahl. [e] Hort. kew. [f] Curtis, Withe. Lightf.

[g] Linn. [h] Hort. kew. [i] Ibid. [k] Eng. bot. Woodw. Mſs. Withe. Curtis, Woodw. Mſs. Withe.

50. This is a very ſmall plant. Stems two or three, round, ſimple, five or ſix inches long, proſtrate. Leaves thick, ſolid, round, ruſſet or glaucous underneath without nerves. Flowers three or five, terminating, large; petals oblong, toothed at the end, and often turned back. Calyx ſmooth, with blunt rounded ſegments. Stamens from forty to forty-five.

The leaves differ from thoſe of all the other ſpecies in being thick and fleſhy, though very hard, and uniform throughout.

Native of Dauphiné near the Grande-Chartreuſe [1].

51. Root with capillary fibres. Stem ſmooth, ſeldom branched, panicled at top, a foot high. Branches either few from the root, or ſeveral from the upper part of the ſtem, capillary, oppoſite, upright, like the ſtem. Leaves oppoſite, ſubcordate, blunt, ſmooth, reflex and waved a little on the edge; nerved, paler and dotted underneath; upright, often complicated, ſhorter than the internodes, the upper and lower ſmaller. Flowers ſmall, peduncled, ſolitary and terminating in the axils of the panicle. Bractes oppoſite, lanceolate, acuminate, entire, ſmooth, under each branch of the panicle. Peduncles capillary, one-flowered, upright. Calyx divided almoſt to the baſe; ſegments oblong, acute, erect, permanent. Petals oblong, the ſame length with the calyx. Filaments in ſeveral ſets, connected only at bottom, capillary, a little ſhorter than the corolla, yellowiſh; anthers round. Styles diſtant, the length of the corolla; ſtigmas blunt. Capſule oblong, acute, ſmooth.—It differs from H. quadrangulum in being many-times ſmaller, and in having a weak ſtem decumbent at the baſe:—from H. perforatum in the ſame circumſtances, and in having a quadrangular ſtem.

Native of Japan, and flowering there in june.

52. Stem upright, purple, ſmooth, ſimple or branched only at top. Branches oppoſite, ſubaſſtigiate, like the ſtem. Leaves, oppoſite, entire with a reflex margin, veined, ſmooth, preſſed almoſt cloſe to the ſtem: the lower longer, the upper ſhorter than the internodes. Flowers terminating, about three together. Peduncles and pedicels filiform, like the ſtem, leafy, faſtigiate. Calycine ſegments lanceolate, ſmooth, almoſt the length of the corolla: which is ſcarcely longer than the ſtamens.

Native of the mountains of Japan, flowering in auguſt [m].

53. Stem round, a long ſpan in height. Leaves glaucous, linear, narrow, like thoſe of Linaria, in fours [n]. Stipules commonly on each ſide ſolitary, or two to each leaf, of the ſame ſize and form with the leaves: hence when the leaves are oppoſite there are ſix at each joint, four of which are ſtipules [o]. Flowers terminating, in a looſe ſpike, on one-flowered peduncles. Peduncles and bractes full of large black glands. Petals large in proportion to the plant, marked with lines [p].

This is an elegant little evergreen, forming a pretty buſh, and flowering during moſt of the ſummer.

Native of the South of Europe and many parts of the Levant, the Crimea, &c [q]. It was cultivated here in 1640 [r].

54. Leaves glaucous, preſſed cloſe to the ſtem, ſcarcely conſpicuous.—Native of Virginia, in watery places [s].

55. Stem ſhrubby, four-cornered, hairy, branching like Horſe-tail. Leaves very ſmall, hairy, preſſed ſo cloſe to the ſtem as to be ſcarcely viſible. Flowers golden-coloured [t].

Native of Virginia and Carolina. Introduced in 1787 by Thomas Walter, Eſq.

56. Stem ſhrubby, ſmooth, with a brown wrinkled bark. Branches oppoſite, muricated by the fallen leaves, jointed; the lower joints ſhorter, obſcurely four-cornered; the upper ones alternately compreſſed, ancipital, dilated towards the top. Leaves oppoſite, ſeſſile, longer than the internodes, approximating, quite entire, veinleſs, even. Flowers terminating, ſolitary, the ſame ſize as in H. balearicum, on very ſhort peduncles. Corolla longer than the calyx. Germ ovate. Style ſemitrifid [u].—Native of Arabia.]

57. Root compoſed of many woody fibres ſtriking deep into the ground. Stems ſeveral, ſhrubby, near two feet high, covered with a purpliſh bark. Leaves ſtiff, ſmooth, about two inches long, and a quarter of an inch broad, oppoſite, ſeſſile, of a lucid green on their upper ſurface, and gray underneath, having many tranſverſe veins running from the midrib to the border. Flowers terminating in ſmall cluſters, each on a ſhort peduncle. Calycine ſegments divided almoſt to the bottom, obtuſe, deep purple. Petals large, obtuſe, bright yellow, concave. Germ ovate. Stigmas five, ſlender, bending on one ſide.

It continues in flower from march to ſeptember.—Native of China, whence the ſeeds were brought to Hugh Duke of Northumberland; the plants were raiſed at Stanwick in 1753, and communicated to the botanic garden at Cheſſea.

[*General Remarks.*

If the following remarks be attended to in conjunction with thoſe which were made at the head of the above deſcriptions, the inveſtigation of the numerous ſpecies will be facilitated.

1. All the ſpecies are perennial except the 31ſt.

2. The following are herbaceous—6. 8. 12. 31. 36. 39. 42. 48, 49, 50, 51, 52.

Moſt of the reſt are ſhrubby, or at leaſt ſuffruticoſe, or woody at the baſe.

The ſtem is Cylindrical in 8, 9, 10. 27, 28. 31, 32, 33. 37. 40, 41, 42, 43. 45, 46. 48, 49, 50. 52, 53.—Ancipital or two-edged in 13. 24, 25. 29. 39. 47.—Quadrangular in 1 to 6. 12. 14. 17, 18. 21. 36. 38. 44. 51. 55, 56.

4. The leaves are alternate only in the 7th and 8th ſpecies: in the reſt they are oppoſite.

5. The flowers are in Racemes or Panicles in 3, 4. 6. 8. 10. 17. 24. 29. 31. 34. 35. 36, 37, 38. 42. 45, 46. 48. 51.—In Cymes in 13 and 47.—Umbels in 9.—Corymbs in 21. 27. 33.—Solitary in 1, 2. 5. 7. 11. 18, 19. 36. 56.

6. Some of the ſpecies have Bractes or floral leaves, as 5. 7. 28. 36. 45. 48. 51. 53. and probably ſeveral others: many however have none.

7. Some ſpecies have five or three nectareous glands alternate with the ſtamens, as 3, 4. 9, 10. 20. 25. 32. Probably future obſervation will inform us that others alſo have theſe glands.

8. The fruit in moſt ſpecies is a Capſule; in 3, 4. 10. 13, however it is a Berry, or rather a berried Capſule; being a Berry rather in appearance than ſtructure.

9. Natives of Europe are 1. 13. 24. 36, 37, 38, 39, 40, 41, 42, 43. 45. 47, 48, 49. 50. 53. Of theſe 13. 36, 37, 38, 39. 42. 45. 48, 49, are natives of Britain. The reſt are found in the Eaſt Indies, America, Japan, &c.

10. Though our common St. John's-wort (n. 37.) be named Perforata by ſome old writers, and H. perforatum by Linnæus, from the remarkable veſicles appearing as pellucid dots in the leaves; yet we muſt remember that this ſpecies poſſeſſes the character in common with ſeveral others, though not ſo evidently to the naked eye. This circumſtance is ſaid to have given riſe to the generic name; the dots being like lenſes, through which the *icones* or images of objects may be diſcerned.

PROPAGATION AND CULTURE.

Of the numerous ſpecies above recited that have been introduced into culture in Europe, many are very hardy, and being perennial may eaſily be increaſed by parting the roots, as well as by letting the ſeeds ſcatter. Theſe hardy ſorts are 4, 5, 6. 13, 14. 22, 23, 24. 29. 31. 34. 36, 37, 38, 39. 42. 45. 48, 49. 53. 55. The reſt require the protection of a greenhouſe, but none are ſo tender as to need the aſſiſtance of a bark ſtove.]

[1] Villars. [m] Thunberg. [n] Haller. [o] Linn. [p] Haller. [q] Curtis. [r] Hort. kew. [s] Linn. ſyſt. and Clayton in Gron. virg. [t] Pluk. and Clayton in Gron. virg. Hort. kew. [u] Vahl.

1. Warted St. John's-wort requires no artificial heat. If the plants be placed in a dry airy glaſs caſe in winter, where they may be protected from froſt, and enjoy a good ſhare of freſh air in mild weather, they will thrive better than in a warmer ſituation; but they muſt by no means be placed in a damp air, for their ſhoots would ſoon grow mouldy and decay; nor ſhould they have much water during the winter. In ſummer they ſhould be expoſed to the open air, and in warm weather they ſhould be gently watered three times a week; and they ſhould have a looſe ſandy ſoil not over rich.

This is propagated by cuttings planted in june, in pots filled with light earth, and plunged into a very moderate hot-bed, ſhading them from the ſun, and refreſhing them with water. They will put out roots in ſix or ſeven weeks, when they ſhould be carefully taken up, and each planted in a ſeparate ſmall pot, placing them in the ſhade till they have taken new root; then they may be removed to a ſheltered ſituation where they may be remain till froſt comes, when they ſhould be put into a greenhouſe or glaſs-caſe.

It may alſo be increaſed by ſeeds ſown in autumn. See n. 15.

2. This and the other North American ſorts, ſeldom producing ripe ſeeds here, may be increaſed by parting the roots in autumn. It ſhould have a light ſoil and an open ſituation.

5. Garden Tutſan is eaſily propagated by parting the roots in october: theſe ſpread and increaſe very faſt, where it ſtands long unremoved.

13. Growing wild in woods is not often admitted into gardens; it may be increaſed by parting the roots, and loves ſhade with a ſtrong ſoil. [It is not unfrequently ſeen in plantations among other ſhrubs, where it is as ornamental as many others.]

14. This alſo is uſually propagated by parting the roots in ſeptember, becauſe the ſeeds ſeldom ripen in this country. It will live in the open air, in a warm ſituation and dry ſoil: but it will be proper to keep a plant or two in pots, to be ſheltered under a frame in winter, to guard againſt ſevere froſt.

If this be increaſed by ſeeds, they ſhould be ſown ſoon after they are ripe, in pots filled with light earth, and placed under a frame in winter; in ſpring the plants will appear, and when they are fit to remove may be planted in a warm border or in pots, and treated as the old plants.

20, 23, 24. Theſe are propagated by ſuckers, taken off in march juſt before they begin to ſhoot, and planted in a light dry ſoil: or by cuttings, planted at the ſame ſeaſon: or by ſeeds, ſown in auguſt or ſeptember, as ſoon as they are ripe: but as they multiply faſt by ſuckers, the other methods are ſeldom practiſed.

[36, 37, 38, 39. 42. 45. 49. Theſe being wild plants are ſeldom cultivated in gardens, they are not however without their beauty, and may be increaſed by parting their roots or permitting their ſeeds to ſcatter.

53. Is propagated by cuttings, and may ſtand in the open air, with a reſerve of plants in caſe of very ſevere weather. It is however commonly conſidered as a greenhouſe plant.]

57. Chineſe Hypericum may be propagated by ſlips from the root, or by laying down the branches. If by ſlips, they ſhould be planted in the ſpring on a moderate hot-bed: the layers ſhould be made at the ſame time to take root by autumn, when they may be tranſplanted into pots, and ſheltered under a frame in winter: in ſpring, part of theſe may be ſet in a warm border, and the others continued in pots to be ſcreened in winter. Thoſe plants which ſtand abroad will not flower in winter, as thoſe do which are removed into ſhelter in autumn.

DESCRIPTION, *&c.*

Stems and branches ſlender. Leaves alternate, long, narrow, lanceolate, ſmooth, acuminate, marked with lines, ciliate, embracing. Some of the ſtems are erect, others decumbent, the latter throw out roots. Flowers in capitate bundles: each compoſed of a male flower, involved in a long ſharp bractæ, ciliate at the edge, and a female flower included in three bractes of the ſame form: they are axillary, and on a ſlender pedunculc.

This little plant is a native of Guiana, and grows three or four feet under water; it flowers in februaryª.

HYPNUM. (*Υπνος of Dioſcorides: ſaid to be from* ὑπνος, *ſleep.*)

Lin. gen. Schreb. n. 1656. *Hedw. fund.* 2. 94.

Nat. order of *Muſci* or *Moſſes.*

GENERIC CHARACTER.

CAPS. oblong. *Periſtomium* double: *outer* with ſixteen broadiſh teeth; *inner* membranaceous, equal, laciniated: ſegments broadiſh, with capillary ones interpoſed.

MALES gemmoceous on different plants.

Or thus,

Pedunccle from a lateral tubercle, fenced with ſcales: *capſule* outer fringed with ſixteen teeth.

Male a bud, generally on a different plant. *Withering.*

Hypnum is a very numerous genus of Moſſes. Some of the Linnean ſpecies have been ſeparated by Hedwig and others under diſtinct genera.

There are fifty ſpecies in the 14th edition of the Syſtema vegetabilium. Forty in Hudſon's Flora Anglica: and ſeventy in the Arrangement of Britiſh Plants by Dr. Withering, who to facilitate the inveſtigation of the ſpecies has thrown them into ſeven diviſions. Figures of them may be ſeen in Dillenius, Hedwig, Dickſon, who has diſcovered ſeveral new ſpecies, Engliſh Botany, Vaillant, Buxbaum, Moriſon, &c.

Leaves sinuate-lyrate, stem with scaly appendixes at top.

DESCRIPTIONS, *&c.*

1. Root perennial, almost fusiform, thickish, somewhat woody, sometimes divided, dark brown on the outside, white within, milky, putting up one, sometimes two or three stems, among abundance of radical leaves. Stem about a span high, straight, thickening towards the top, hollow, round, striated, hirsute, quite simple, always one flowered. Root-leaves lanceolate, entire with the edges repand-toothed, hirsute above and below, spotted with black but not always. Stem-leaves two or three, remote, sessile, lanceolate, repand-toothsetted, flat, hirsute, gradually smaller. Flower very large, from erect spreading. Calyx cylindrical rather than round, very irregular; scales bluntly lanceolate, hirsute, keeled, winged as it were on the sides with a broadish serrate membrane; some of the outer ones are wholly membranaceous without a keeled back, and these are pushed back within the grooves of the inner scales. Corollets very numerous, long, deep yellow, five-toothed, from erect spreading, with yellowish white villose hairs at the base. Seeds from an ovate base gradually attenuated, naked, with a sessile feathered down at top. Chaffs of the receptacle the length of the calyx, yellow and subserrate towards the top. The plant has no smell[a].

Allioni observes, that the calyx is thicker than in the next species, with which this has been confounded; the stem leafy, the leaves continually smaller and upright; the scales of the calyx not only bearded with black villose hairs, but jagged and ciliate on the edge: whereas in H. maculata the leaves are wider, and the root-leaves spread on the ground: the stem almost naked, often branched, and higher; the scales of the calyx not jagged.

According to Monf. Villars, the stem is solitary, two feet high, very thick and villose, with the leaves at the bottom, but naked or having a single leaf only, from the middle to the top, where it spreads out, becoming more villose on the outside, and more hollow within. Leaves oblong, villose, pointed and toothed, raised up and not lying on the ground, nor spotted. Calyx very large and villose, composed of large slatted scales, with the lateral membranes cut and jagged irregularly, like some species of Centaurea. Seeds very long, fusiform, crowned by a feathered stiped egret. Chaffs longer than the seeds, and almost as high as the hairs of the egret.

Native of the mountains of Carinthia, Dauphiné, and several parts of the Alps.

2. Root thick and long, abounding with milky juice, as does the rest of the plant. Leaves all radical, except the plant becomes luxuriant from cultivation; oblong, somewhat pointed, very irregularly toothed, rough spotted (as in the stem) with red or brown spots. Stem commonly simple, roughish, with one or two distant, lanceolate bractes, and terminated by one large flower. Outer scales of the calyx rough with black prominent bristles, intermixed with scattered white ones: the inner smooth, yellowish, half as long as the florets, hairy, composed of large scales. The flower opens at six in the morning, and closes at four in the afternoon. Seeds wrinkled. The stem, though generally simple, has sometimes a branch or two.

The leaves are boiled in Smoland and eaten like cabbage, though bitter they are eaten green by animals, particularly those which ruminate, greedily. The country people believe the plant to be a cure for tetters, and other cutaneous eruptions, possibly on account of its spotted leaves[b].

Native of many parts of Europe. In England not common. On Gogmagog hills, Newmarket heath, &c. in Cambridgeshire. Bernack heath, in Northamptonshire. About Malham Cove, Cartmell Wells, and near Settle in Yorkshire, &c. flowering in july, and perennial.

3. Root annual, the thickness of a crow quill, tapering, furnished with few fibres, pale brown. Root-leaves numerous, spread on the ground, about the length and breadth of the little finger, sinuate-toothed,

[a] Jacquin misc. [b] Engl. bot. Relh. With. Woodw. Mss.

a little

a little broader at top, ſmooth, but not perfectly ſo, the edges particularly being thin ſet with ſtiffiſh hairs; thoſe on the ſtem few, and very minute. Stems uſually ſeveral, about ſeven inches high, nearly upright, divided into two or three branches, round, almoſt naked, glaucous. Peduncles ſcaly, a little thickened under the flower. Flowers very ſmall. Calyx at firſt cylindrical; but, when the flowering is over becoming of an oblong conical ſhape, and large; the ſcales ſmooth, ovate-lanceolate, unequal, with red tips. Tube of the corollet with a few ſtiffiſh hairs at top; the border five toothed. Chaffs of the receptacle concave, ſhining, deciduous. Seeds ſublinear, tapering to a point at bottom, cheſtnut-coloured; viewed with a magnifier finely grooved and rough. Down unequal, ſtiffiſh [e].

The ſtem is ſometimes ſimple, in the autumn it is much branched and reclining. Leaves ſhining, and their teeth triangular, ſometimes edged with white hairs [d].

It may be diſtinguiſhed by the ſmallneſs of the flowers, not exceeding the ſize of a ſilver three-pence, while the heads containing the ſeeds are altogether as large in proportion to the ſize of the plant. The flowers are open from about nine in the morning till about one or two in the afternoon. It delights in a gravelly or ſandy ſoil, and expoſed ſituation, and flowers in june [e].

4. Root perennial, the thickneſs of the little finger, running deeply into the earth, generally ſimple, of a whitiſh colour, and milky within. Root-leaves ſpread on the ground, oblong-wedge ſhaped, waved or toothed, hairy, the hairs ſimple, upright, and proceeding from little prominent points. Stems often ſeveral, from one to two feet high, nearly upright, naked, inſtead of leaves having only ſhort, ovate, pointed, ciliate ſcales at the baſe of each branch; they are very ſmooth, glaucous, ſomewhat ſtriated, tough and ſolid; the ſcales are lanceolate, with a few white briſtly teeth at the baſe on each ſide. Peduncles long beſet with a few ſcales, a little thickened towards the top, one-flowered. Flower large, cloſing at three in the afternoon. Calyx not diſtended at the baſe; ſcales ovate or linear-lanceolate, pointed, ſmooth, reddiſh at top, with a row of ſhort, taper, dark purple briſtles along the upper part of the keel. Tube of the corollet hairy at top; border reddiſh green on the outſide, five-toothed. Seeds rough and finely grooved, reddiſh. Stipe of the down longer than the ſeed; down rather longer than the ſtipe. Chaffs linear, long, ſhining, membranous, concave, tapering and yellow towards the top.

It is diſtinguiſhed from Leontodon autumnale by the length of the root, whence it derives the trivial name; and is common on dry banks, heaths and paſtures, flowering from may to ſeptember; in the early part of ſummer it is a conſpicuous plant.

In barren ſoils it occurs of a much ſmaller ſize, five or ſix inches high, with an unbranched ſtem, or with one flower almoſt ſeſſile on the ſide [f].

Theſe plants are named Hawkweed in Engliſh, in common with many others; Dr. Withering calls them *Cat's-ears*.

5. Root downright, two or three inches long, annual, fibrous. Root-leaves decumbent, ſomewhat rugged. Stem naked, ſimple, one-flowered, or ſometimes divided into two or three one-flowered branchlets: towards the top are ſome ſmall, linear ſcales, preſſed cloſe to the ſtem, and mortified at the ſides. Stem a palm in height, ſmooth. Flower ſmall, equal. Calyx almoſt calyculate; ſcales unequal, acute, mortified at top. The flowers are open from eleven in the morning to two in the afternoon. Seeds in the circumference with a ſeſſile ſimple down; in the diſk they are on a very long ſtipe. Chaffs of the receptacle minute.

Native of Italy, near Naples, on volcanic ground, particularly the Solfatara; flowering from may to july [g].

Lour. cochinch. 200.
Stemless, hairy, scape one-flowered, capsules oblong.

DESCRIPTIONS, &c.

1. Leaves like those of Carex or Juncus pilosus. Scape shorter than the leaves, upright, hairy. Bractes two, awl-shaped, upright, between which is one sessile flower (sometimes two) the length of the bractes[a].

Hypoxis juncea or Rushy Hypoxis of Dr. Smith, found by Mr. John Fraser in boggy ground in Carolina, does not seem to be a different species, although the scapes are single-flowered, as in Smith's and Catesby's figures; whereas in those of Petiver and Plukenet, referred to by Linneus, two flowers are represented together. It is thus described by Dr. Smith.

Root tufted, with fleshy branched fibres. Leaves radical, several, rushy, a span long, erect, a little recurved at the top, linear, pointed, entire, keeled; channelled and bare on the upper side, hairy on the back; dilated and sheath-like at the base. Stems two or three, shorter than the leaves, upright, round, hairy, reddish above, each bearing one upright flower, in size and appearance like that of Ornithogalum luteum. Corolla externally green and hairy, with a red rib; internally concave, yellow, smooth, without veins or nerves. Stamens much shorter than the corolla: filaments cylindrical, three a little longer than the other three: anthers oblong, incumbent, cloven at the base, after discharging their pollen becoming shorter and almost round. Germ obconical, slender, scarcely perceptible till after flowering: style very short: stigma triangular, feathery.

Native of North America. Introduced in 1784, by Mr. William Young. It flowers in june[b].

2. Bulb roundish, fleshy, brown, putting out fibres from the side. Leaves radical, sheathing at the base, forming as it were a short stem, grassy, keeled, a span long, recurved, sharp, striated, somewhat hairy. Peduncles radical from the sheaths among the leaves, about flowering time short, but afterwards lengthened out, filiform, two-edged, few-flowered. Spathes two-leaved; leaves small, linear, pubescent. The three outer parts of the corolla lanceolate, acute, hairy on the outside, permanent; the three inner smooth, yellow, greenish on the outside, withering. Stamens alternate with the segments of the corolla, three longer, three shorter: anthers sagittate. Germ oblong: style awl-shaped: stigma blunt. Capsule oblong, three-cornered, crooked, rough with hairs, crowned with the permanent corolla. Seeds wrinkled, black[c].

Native of Jamaica, in sandy fields among the mountains. The roots came accidentally to Mr. Miller among some plants of Allspice[d]; and he cultivated them in 1755. It flowers most part of the year[e].

3. Root composed of capillary fibres in bundles. Leaves radical, many, entire, three-nerved, shorter than the scape, a span in length. Scape filiform, slightly angular, flexuose, upright, villose, a foot high. Flowers from the middle to the top of the scape, in spikes, alternate, remote, very many. Capsule and rachis very rough with hairs. Native of Japan; flowering in may and june[f].

4. Bulb globular. Leaves ensiform, subciliate, toothletted at the base, on the keel and about the edge. Scapes leafless, without bractes. Spathe hidden. Corolla yellow, green on the outside. Anthers bifid at the base. Native of the Cape of Good Hope, on sandy hills: found there by Thunberg[g]. Introduced in 1788, by Mr. Francis Masson[h].

5. This is a beautiful little bulbous plant, with a dark spot at the claws of the petals. It was first named Amaryllis capensis by Linneus, and is thus described in the Amoenitates Academicæ.—Leaves like those of Narcissus, the length of the scape, which is sheathed below the middle; the spathe permanent, acuminate, flat; petals lanceolate, black at the base within; filaments very short; anthers erect, shorter by half than the petals; style three-cornered, the length of the anthers, with three stigmas. Amaryllis capensis of Miller is different. Reichard refers to A. vernalis of Miller as the same with this; but Miller makes that to be a native of Spain and Portugal.

Native of the Cape of Good Hope, where it was observed by Thunberg[i]. It was introduced in 1788, by Mr. Francis Masson[k].

6. Leaves radical, loose, bending at the end. Scapes filiform, the height of the water. Flowers in some solitary, hermaphrodite; in others umbelled, male. Native of the Cape of Good Hope in watery ditches[l]. Introduced in 1787, by Mr. Francis Masson[m].

7. This also was found at the Cape of Good Hope by Thunberg[n]; and was introduced by Masson in 1788. It flowers in july[o].

8. Capsule small, narrower at the base so as to be almost club-shaped, knobbed with the protuberating seeds, villose, membranaceous, very thin, valveless, of a herbaceous colour on the outside, within smooth and coloured. Partitions very thin, fixed to the axis and walls of the capsule. Seeds two or three only in each cell, subglobular, black, small, rendered a little rugged by very minute raised dots, fixed to the inner angle of the cells in a single row. Embryo straight, the length of half the albumen[p].

It varies in size, and is a native of the Cape of Good Hope[q]. It was found there by Mr. Francis Masson; was introduced in 1774, and flowers most part of the summer.[r].

9. Native of the country about Aleppo.

10. Leaves several, a long span in length, keeled, like those of Juncus pilosus, hairy all over, but most conspicuously round the edge, pale green on both sides. Among the leaves, at bottom, spring out sessile oblong heads, bluntly three-cornered, at the top of which are the flowers. Petals pointed, plaited; three outer, broader, green, hairy; three inner narrower, smooth, yellowish green. Stamens inclosed within the corolla, which kept close, or opened very little. Seeds round, black, shining. It flowers at the end of june, and in july. Native of Carolina, whence it came in the earth with other plants, and was cultivated in the Eltham garden before 1732[s].

11. Bulb conical, large in proportion to the plant, truncated and margined beneath, and having linear converging scales at top. Leaves radical, somewhat fleshy, acute, longer than the scapes, a finger's length. Scapes several, very short, almost cylindrical, involved in scales at the base; branches or pedicels one-flowered. Corolla spreading, snow-white. Filaments shorter than the corolla. Anthers hastate, upright, longer than the filaments. Germ oblong. Styles three, membranaceous, adhering to the germ in a paramidal form. Native of the Cape of Good Hope, where it was found by Koenig[t].

12. Flower white and pretty. Found at the Cape of Good Hope by Thunberg.

13. This is a little plant, found also at the Cape by Thunberg[u].

14. This is an annual plant. Leaves awl-shaped, channelled, reflex, half a foot long, clustered. Scape round, slender, equal to the leaves. Corolla bell-shaped, equal, golden-coloured within, greenish on the outside, hairy. Capsule oblong, three-sided, hairy. Native of Cochinchina, on a sandy hill called Son Koung[x].

PROPAGATION AND CULTURE.

For the Cape sorts (4 to 8, 11, 12, 13.) see Albuca.

2. Trailing Hypoxis will not thrive well in England, unless the pots be plunged into a hot-bed of tanners'-

bark, and the air kept up to the heat assigned for Ananas. In this situation the plants will thrive, produce plenty of flowers, and perfect their seeds, which if suffered to scatter on the pots will produce plenty of young plants; or if they be sown in pots soon after they are ripe, and planted into the tan-bed, they will come up in about six weeks, and when they are fit to transplant may be treated in the same manner as the old plants [1].

2. Hyptis capitata.

Jacqu. collect. 1. 102. *Plum. cat.* 6. *ic.* 155. *t.* 163. *f.* 2. (Melissa.]

Leaves ovate, flowers in heads.

DESCRIPTIONS.

1. This is a shrub ten feet in height, with one or two upright stems, near an inch in diameter, smooth, brownish ash-coloured, round and woody; but the younger branches are four-cornered and harbaceous. Leaves opposite, petioled, long-lanceolate, acute, unequally serrate, smoothish, from three to six inches in length. Whorls on the younger branches at the leaves sessile, six-flowered. Corolla white, with the segments of the upper lip purple in the disk. Calyx a little hispid on the back, and at the edges of the segments. Anthers pale yellow. Native of St. Domingo.

2. Stems suffruticose, two or three feet high or more, becoming woody, commonly four-cornered, brown. Branches annual, herbaceous, subdivided, four-cornered, roughish, two feet long. Leaves opposite, petioled, ovate, but with a sharp base, veined, unequally serrate, acute, a little hairy on both sides when viewed with a glass, dark green; the lower ones wrinkled, the largest seven inches long. Peduncles, axillary, solitary, four-cornered, slender, from two to three inches long, bearing at the end numerous flowers collected closely into a semiglobular head, supported underneath by an involucre compoled of many lanceolate leaflets. The tube of the corolla is a little hairy on the outside, but most so on the back of the helmet. The whole petal is white, with sometimes a tinge of flesh-colour. Calyx green, and a little hispid. Anthers yellow. The whole plant is inodorous. Native of St. Domingo, flowering there in december and january [2].

Stem sharp, quadrangular.

DESCRIPTIONS, *&c.*

1. Height a foot and half. Stems first square, afterwards round, with small sessile leaves in pairs on their lower part, and seven or eight very narrow erect leaves or bractes, springing from the same joint: on the upper part flowers in whorls, the lower ones half an inch apart, the upper almost joined. Anthers twin. Seeds black. The whole plant has a strong aromatic scent. It flowers in july and august, and the seeds ripen in september. The roots will abide many years.

[Root woody, hard, the thickness of a finger. Stems very numerous, from a foot to eighteen inches high, shrubby, straight, not much branched, whilst tender square, but becoming round as they grow woody. Leaves numerous, narrow, smooth, entire, like those of Lavender, but much shorter, acute, dotted. Whorls of flowers from the bosoms of the leaves, on two many-flowered peduncles shorter than the leaf, directed one way, and continued into a spike. Corolla blue, varying to red and white [3].

[1] Mill. lg. [2] Jacquin. [3] Ray & Haller.

Native

Native of the South of Europe, and Siberia, Miller ſays the Levant. Cultivated in 1596 by Gerarde [b].

There are many varieties of Hyſſop; Ray enumerates nine from Parkinſon and others. Mr. Miller makes that with red flowers to be a diſtinct ſpecies, not growing ſo tall as the common ſort with blue flowers, branching more, the ſpikes of flowers much ſhorter, the whorls cloſer, having long narrow leaves under each, the corolla of a fine red colour. It is more tender, all the plants having been deſtroyed in the ſevere winter of 1739. That with white flowers does not differ from the blue in any other particular.

[Hairy Hyſſop, which Parkinſon calls Ruſſet Hyſſope, differs no otherwiſe than in the woollyneſs of the ſtem and leaves, giving them an aſh or ruſſet colour.

The leaves vary in colour as well as the flowers, ſome being white, ſtriped with white, or half green, half white. H. fol. niveis. *Park. parad.* 455.—Others with the leaves wholly yellow, or but a little green in them. H. aureus; yellow or golden Hyſſop of Parkinſon; which he ſays is of ſo pleaſant a colour, that it provokes many Gentlewomen to wear them in their heads and on their arms, with as much delight as many fine flowers can give. The leaves are alſo ſometime curled, or crampled at the edges, as Parkinſon ſpeaks, ſo that each leaf ſeemeth to be compoſed of many: or jagged and dented, foliis crenatis: or larger and broader, on more woody ſtalks. H. latifolia of Parkinſon [c].

Hyſſop alſo varies in the ſtem, which is ſometimes much higher than common;] hence H. altiſſimus of Miller, n. 3., which beſides having a much taller ſtem, has narrower leaves, the whorls farther aſunder, the ſpikes much longer, the flowers larger, and of a deeper blue, and the plant leſs odorous. [Sometimes it is lower; as in H. minor and humilior myrrhi folio of Tournefort, which has the leaves a little blunter and ſhorter than in the common ſort [d]: H. minor ſ. hiſpanica of Parkinſon; H. parva anguſtis foliis of Lobel; and H. ſurculis denſis, or double Hyſſope of Parkinſon, which is not only of lower growth, but is more branched, ſlenderer, and not ſo woody, leaning towards the ground, more thick ſet with leaves, which are of a darker green, and thicker conſiſtence. He recommends it as fit to border a knot of herbs or flowers, becauſe it will abide, and not grow too woody or great, nor be thin of leaves in any part, but may be kept cutting ſmooth and flat.

Although the flowers commonly are directed all one way, yet ſometimes they point two different ways; hence H. utrinque florifera of Dodonæus.

And laſtly, the ſcent is ſometimes ſtronger than common, approaching to that of Muſk: hence H. moſchata vel de Cililia, or muſked Hyſſope of Parkinſon.]

2. Root ſtrong, fibrous, perennial, ſending out many ſquare ſtalks, which divide into ſmaller branches. Leaves oblong, crenate. Flowers produced at each joint in ſmall cluſters; two peduncles ſpringing from the baſe of the leaves, about half an inch long, both inclining to one ſide of the ſtalk; each of theſe divides again into two ſmaller, and theſe each ſupport a cluſter of four or five flowers, with ſwelling tubulous calyxes. The tube of the corolla is longer than the calyx; the lips are oblique to it, being placed horizontally; the colour is blue. The flowers appear in June and July, and the ſeeds ripen in ſeptember.

It grows naturally in Siberia. The ſeeds were ſent to Mr. Miller from the imperial garden at Peterſburgh, and afterwards from Holland. [He cultivated it in 1759 [e].]

3. Root perennial. Stem upright, near four feet high. Leaves oblique heart-ſhaped, ſerrate, acute, on ſhort foot-ſtalks. Flowers yellow, in cloſe thick ſpikes four or five inches long. Upper lip of the corolla divided into two roundiſh ſegments; the two ſide ſegments of the lower lip erect, the middle one reflex, acutely ſerrate at the end. Seeds brown.

[Native of Virginia and Canada. Cultivated in 1692, in the Botanic Garden at Oxford [f].

[b] Hort. kew. [c] Theat. p. 2. [d] Gouan illuſtr. [e] Hort. kew. [f] Ibid.

Gouan remarks that it has the appearance of Galeopſis; that the ſtem is either green and very even, with ſmooth leaves; or hairy, tinged with purple, and hairy leaves; that the ſpikes are cylindrical, nearly as thick as the little finger, three inches long, very ſmooth and cloſe; that the bractes are large and cordate-ovate; and that there are from four to eight flowers to each bracte.]

There is a variety with purple ſtalks and flowers, the leaves on longer foot-ſtalks, and the ſpikes of flowers thicker.

PROPAGATION AND CULTURE.

1. Common Hyſſop with all its varieties may be propagated either by ſeeds or cuttings; if by ſeeds, they muſt be ſown in march, upon a bed of light ſandy ſoil, and when the plants come up, they ſhould be tranſplanted out to the places where they are to remain, placing them at leaſt a foot aſunder each way; but if they are deſigned to abide in thoſe places for a long time, two feet diſtance will be ſmall enough, for they grow pretty large, eſpecially if they are not frequently cut, to keep them within compaſs. If you would propagate them by cuttings, they ſhould be planted in april or may, in a border where they may be defended from the violent heat of the ſun; and being frequently watered, they will take root in about two months; after which, they may be tranſplanted where they are to continue, managing them as was before directed for the ſeedling plants.

They are very hardy plants, which will endure the cold of our winters in the open air, provided they are planted in a dry undunged ſoil; for when they are planted in a rich ſoil, they grow very luxuriant in ſummer, and are leſs able to reſiſt the cold in winter; ſo that when any of theſe plants grow out of the joints of old walls, as they frequently do, they will reſiſt the moſt ſevere froſt, and will be much more aromatic than thoſe which grow in a rich ſoil.

2, 3. Both theſe ſorts are alſo very hardy, and may be eaſily propagated by ſeeds ſown in autumn, for thoſe ſown in the ſpring often lie a year in the ground before they vegetate: when the plants come up, keep them clean from weeds, and thin them where they are too cloſe. The following autumn tranſplant them where they are to remain, and the roots will abide ſeveral years.

DESCRIPTIONS, &c.

1. [This is a very elegant upright shrub, seldom more than four or five feet high. Trunk round, thicker and knobbed where the branches come out, covered with an ash-coloured bark. Branches four or five from each joint towards the top, in whorls, spreading, stiff, round, grooved, brittle, hoary, subdivided, and forming altogether a near globular head. Leaves scattered, alternate, petioled, clustered towards the ends of the twigs, wedge-shaped, ovate, obtusely margined, quite entire, veinless, smooth, pale underneath, with very minute black dots. According to Jacquin, they are of different shapes between oblong and roundish, sometimes blunt, sometimes emarginate, but always with a little rigid point, rigid, narrowing into a very short petiole, and sometimes rolled back at the sides. Racemes terminating, commonly shorter than the leaves, about two inches long, solitary, erect, loose, simple, seven-flowered or thereabouts. Peduncles scattered, spreading, one-flowered. Flowers small, stiffish, white, smelling like Jasmine, and retaining their sweet scent several days. Tube of the corolla narrower at the base, dilated above; the five outer segments are spreading and oblong, the five inner inserted into the throat between the outer ones, roundish, crenulate, erect. Filaments from the base of the corolla, shorter than the tube: anthers ovate, white. Germ superior: style short, permanent: stigma blunt, purple. Berry roundish, smooth, the size of a large pea, of a reddish orange-colour, and containing an orange-coloured pulp. Seeds four, sometimes, but seldom, three or five, ovate, smooth, shining, cartilaginous, brownish yellow. The berries are eaten by small birds, and the seeds are strung for bracelets by the Caribees, whence the French in the islands call this shrub *Bois bracelets*, and Linneus gave it the trivial name of *armillaris*. The Spaniards call it *Barbasco* or *Verbascum*.

Native of South-America and the West-India islands; on the calcareous rocks of Jamaica, on the coast, flowering in february and march; in Curaçoa, Martinico, Carthagena, &c [a].

Cultivated by Mr. Miller in 1768 [b].

2. Native of the West-Indies [c].

3. This is a shrub three feet in height, with all the habit of the preceding. It differs in having the leaves lanceolate, acuminate, pungent, extremely stiff, and shorter. The peduncles are pendulous as in that, and one-flowered. Native of South-America. Jacquin observed it at the Havannah in mountain woods, flowering in january and february [c]. It was cultivated in 1729, by James Sherard, M.D. [a].

4. This is a shrub two feet in height, very much branched, of the same habit with the two preceding, but not so neat. Leaves extremely rigid, pungent like thorns, often twisted, subsessile, an inch long, most frequently four together in whorls at each joint. Peduncles one-flowered, solitary, terminating pendulous, shorter than the leaves. Flowers stiffish, and without any smell. Petals white, with all the segments convex, the outer ones spreading, the inner almost erect. Berries yellow.

Native of the island of St. Domingo, about Port au Prince, on the coast, flowering and fruiting in january [c].]

PROPAGATION AND CULTURE.

These plants must be kept in the bark stove, giving them little water in winter, and in warm weather plenty of fresh air. They are raised from seeds, procured from the countries where they grow naturally, and afterwards from cuttings; but it is with difficulty that these take root.

DESCRIPTION, *&c.*

Root annual, rigid, whitiſh and fibrous. Stems many, erect or procumbent, from a ſpan to a foot in height or more, ſomewhat rigid, beſet with ſhort rough hairs, angular, ſtriated, green, often tinged with purple; for ſomething more than one third of their height, they are cloathed with numerous leaves, which are linear or linear-lanceolate, waved at the margins, bluntiſh at the end, hairy on both ſurfaces, ſeſſile, and pointing upwards: the remainder of the ſtem is naked, and terminated by one flowering head. Several alternate branches, much ſhorter and more ſlender than the ſtem, ariſe among the upper leaves, each bearing alſo one head of flowers. Outer ſcales of the calyx ovate-lanceolate, obtuſe, with two or three teeth on each margin, hairy towards the baſe; inner lanceolate, toothed. Proper calyx of five briſtle-ſhaped ſegments. Corolla blue, ſometimes varying to white. Stigma club-ſhaped, purple[a]. Capſule membranaceous, very thin, pyramidal-ovate, two-celled: partition faſtened only to the walls of the capſule. Seeds ſlender, ovate-oblong, very ſmooth, ſhining, of a pale cheſtnut colour. It differs not only from Phyteuma, but from all the Campanaceous plants, by having the partition cloven at the axis[b].

Linnæus remarks that the leaves are obſcurely ſerrated. Leers affirms that the calyx has conſtantly twenty leaflets, in four rows, ſubſerrated, the outer ones gradually larger. The anthers are at firſt almoſt wholly united, but when the pollen is evacuated they ſpread, and are joined only at the baſe. The central florets are barren, with the ſtigma club-ſhaped, quite entire, having pollen ſcattered over it, and not villoſe: the capſules are on very ſhort pedicels, and never ripen. The lateral florets, in greater numbers, are fertile; theſe have alſo a club-ſhaped ſtigma, which becomes afterwards bifid: becauſe the anthers of theſe have evacuated their pollen before the ſtigma burſts, it ſeems probable that the fecundation is made by the anthers of the barren florets. The ſtyles of the barren florets are all upright: but thoſe of the fertile ones are bent down, for the eaſier reception of the pollen. In this curious account of the proceſs of fecundation in this plant, the botaniſt cannot but remark the affinity that it bears in this circumſtance to the genuine plants of the claſs Syngeneſia, where Linnæus placed it, and whence modern reformers have removed it. In its general appearance it ſo reſembles a Scabious as to be taken for one by unſkilful botaniſts.

It is common on dry ſandy grounds, heaths and hilly paſtures, flowering from june to auguſt. The whole plant is milky, and is ſometimes eaten by ſheep. Linnæus ſays, that bees are particularly fond of the flowers.

Ray calls it Rampions with Scabious-like heads, and Withering, Scabious Sheep's-bit.

It varies much in ſize, and on the ſea coaſt of Cornwall it is only about an inch high when full grown, and the whole plant is very hairy.

β. The younger Linnæus, in his Supplement, mentions a variety with perennial roots, the ſtem higher than in the common ſort, the heads of flowers larger. It varies with very ſmooth and very hairy leaves from the ſame root, ſome entire, and others ſerrate. Its native place is unknown; but the ſeeds were communicated by Monſ. Thouin. Villars affirms that the common Jaſione is perennial.

DESCRIPTIONS, &c.

1. Arabian Jaſmine riſes with a winding ſtalk to the height of fifteen or twenty feet, ſending out many ſmall branches. Leaves ſmooth, near three inches long and almoſt two broad, of a light green, on ſhort foot-ſtalks, and ending in acute points. The flowers are produced at the end of the branches, and alſo upon the ſide ſhoots, on ſhort peduncles, each generally ſuſtaining three flowers, the two lower oppoſite, and the middle one longer. Calyxes cylindrical, ſhort, cut almoſt to the bottom into eight narrow ſegments. Tube of the corolla narrow, about half an inch long, cut at the top into eight obtuſe ſegments, which ſpread out quite flat: theſe flowers are of a pure white, and have a moſt agreeable odour, ſomewhat like Orange flowers, but ſweeter; when fully blown they drop out of their cups upon being ſhaken, and frequently fall out in the night, changing ſoon to a purpliſh colour. The plants continue flowering great part of the year, when they are kept in a proper temperature of warmth.

[Reichard, from Fabricius, obſerves, that the calyx is frequently ten or twelve-cleft. Loureiro, that both that and the corolla, though often eight-cleft, yet vary with from ſix to ten ſegments. He deſcribes the ſtem as ſhrubby, four feet high, almoſt upright, knotty, rugged and branched: the lower leaves cordate, obtuſe; the upper ovate, and ſharpiſh; all of them quite entire, wrinkled and ſmooth: flowers four or thereabouts together, always luxuriant and barren.

This beautiful plant, ſo much eſteemed for its highly odoriferous flowers, is a native of the Eaſt Indies, and is much cultivated there, in China, and the Weſt Indies. There are ſeveral varieties of it in thoſe countries. We have it both with ſingle and double flowers, and alſo with large double flowers. The laſt, Mr. Miller ſays] grows naturally at Malabar, and having a moſt agreeable odour, the women there ſtring the flowers to hang round their necks, by way of ornament. It grew in the royal garden at Hampton Court, at the end of the laſt century, but being loſt there, was known in Europe only in the garden of the Grand Duke of Tuſcany, who would not ſuffer any cuttings or layers to be taken from his plants; till Mr. Miller received a plant of it from the Malabar coaſt, by Captain Quick.

This ſort was cultivated here in 1730[a].

Gærtner affirms, that there are two different plants, one a genuine ſpecies of Jaſmine, with ſpherical berries, of a yellow bay colour, a little larger than Juniper berries, and containing a ſingle ſeed, manifeſtly berried; the other approaching in the whole of its ſtructure to Nyctanthes, and a genuine ſpecies of that genus. This he deſcribes under the names of Nyctanthes Sambac, but without determining whether it be that ſpecies or not.

2. Glaucous-leaved Jaſmine is a ſhrub, with round, even, oppoſite branches. Leaves petioled, ſmooth and even. Peduncles terminating, three-cleft or three-flowered. Flowers larger than thoſe of common Jaſmine. Native of the Cape of Good Hope, where it was found by Thunberg[b]; and alſo by Maſſon. It was introduced here in 1774, and flowers in auguſt[c].

3. Found alſo at the Cape by Thunberg[d].

4. Azorian Jaſmine has longer, ſlender branches, which require ſupport, and may be trained twenty feet high. Leaves of a lucid green, and continuing all the year. Flowers terminating, in looſe bunches. Tubes long and narrow, with ſpreading ſegments. The corolla is of a clear white, and has a very agreeable ſcent. Native of the Azores; [of Madeira, according to the Kew Catalogue. Cultivated in 1731, in the royal garden at Hampton Court. It flowers from may to november[e].

5. Branches oppoſite, round, with an aſh-coloured bark; branchlets four-cornered, with lines running down from the baſe of the petioles, ſomewhat rough-haired. Petioles channelled, hairy on the edge. Leaflets veinleſs, three-nerved, ſmooth, the end one larger, all petioled. Peduncles villoſe, ſhorter than the leaf. Flowers pedicelled. Calyx bell-ſhaped, with ſix or ſeven ſmall blunt teeth. Tube of the corolla almoſt an inch and half long; ſegments ſix or ſeven, lanceolate, ſharp, three times ſhorter than the tube. Allied to the preceding, but differing in its angular villoſe branches. Native of the Cape of Good Hope.

6. Branches round, as are alſo the upper leaves, petiols, peduncles and calyxes cinereous-pubeſcent. Leaves on jointed petioles: on the branches ternate:

[a] Hort. kew. [b] Linn. ſuppl. [c] Hort. kew.
[d] Thunb. prodr. cap. [e] Hort. kew. & Mill. dict. ed. 1. n. 9.

the

the leaflets petioled, quite entire, ſmoothiſh except the midrib on both ſides, flat, nerved and ſlightly veined, the middle one two inches long, ovate, the lateral ones ſcarcely half an inch, oblong, on ſhorter petioles; on the flowering branchlets an inch long, oblong, pubeſcent. Panicle terminating, two inches long: peduncles trichotomous, faſtigiate; ſometimes ſolitary, oppoſite from the laſt axils, twice trifid. Bracte linear at the baſe of the peduncles, patulous at the tip. Calyxes five-cleft, obovate, abbreviated, plaited in five corners; ſegments blunt. Corolla an inch long, ſmooth, border only half the length of the tube; ſegments ſix, linear, blunt. Cultivated in Malabar, in the gardens of the idolaters. *Koenig.*

7. Branches round, ſmooth, as is the whole plant. Leaves on ſlexuoſe, perhaps cirrhoſe petioles: leaflets petioled, ovate-oblong, acuminate, obſcurely and ſimply veined, ſhining on both ſides, quite entire, paler underneath, the middle one two inches long, the ſide ones about half the ſize. Racemes oppoſite, ſpreading very much, three times as long as the leaf. Partial peduncles oppoſite, ſpreading very much, one-flowered or three-flowered. Flowers pedicelled. Bracte linear on each ſide at the baſe of the peduncles and pedicels. Cylyx bell-ſhaped, with five or ſix ovate, acute, minute teeth. Corolla an inch and half long; ſegments about ſeven, almoſt the length of the tube. Native of the Eaſt Indies.

8. This is a ſhrub, and ſeems to be climbing. Branches round, ſmooth. Leaflets petioled, two inches long, the ſide ones ſmaller, very ſmooth, obſcurely veined, attenuated. Petioles bent, channelled above, half an inch long. Peduncles ſolitary, oppoſite, ſmooth, the length of the general petiole, angular. Pedicels oppoſite, ſhort, undivided. Calyx bell-ſhaped, obſcurely five-toothed, ſmooth, with minute toothlets [r]. Native of the Society Iſles in the South Seas.

9. Native of the Friendly iſles, in the South Seas [s].]

10. Common Yellow Jaſmine has weak angular branches which require ſupport, and will riſe to the height of eight or ten feet, if planted againſt a wall or pale.

[The calyx is deeply five-cleft [b]. Berry ſuperior, oblong-ſphæroidal, very ſmooth, dark purple: ſkin very thin, diaphanous, pale, when ripe ſeparating ſpontaneouſly from the fleſh, which is ſucculent, coloured, and adheres ſo cloſely to the ſeeds, as to appertain rather to them than to the pericarp. Seeds regularly two, but one only uſually arriving at maturity, elliptic, flatted like a lens, faſtened to the bottom of the berry [t]. Native of the South of Europe and the Levant. Cultivated in 1597 by Gerarde [u].

Beſides the common name of Yellow Jaſmine, Parkinſon has thoſe of Shrubby Trefoil and Make-bate, which are now obſolete.]

11. Italian Yellow Jaſmine is ſo called becauſe the plants were annually brought from Italy by thoſe who came over with Orange trees. The flowers are generally larger than thoſe of the preceding, but have very little ſcent, and are ſeldom procured ſo early in the ſeaſon. [Simple leaves are frequently intermixt with the ternate. The calyx is ſcarcely five-cleft [l].

Its native country is not known. It was cultivated here in 1730, and flowers from july to ſeptember [m].]

12. Yellow Indian Jaſmine riſes with an upright woody ſtalk eight or ten feet high, covered with a brown bark, ſending out ſeveral branches, which want no ſupport. Leaflets of a lucid green, ovate and entire, continuing green all the year, the two ſide ones much leſs than the end one. The flowers are produced at the ends of the ſhoots in bunches; the corolla has a longer ſlender tube, and the ſegments are blunt and ſpreading; the whole is of a bright yellow colour, and has a moſt grateful odour. The flowers come out from july to october and november; and are frequently ſucceeded by oblong oval berries, which turn black when ripe, and have each two ſeeds. [Native of the iſland of Madeira. Cultivated in 1730 [x].

13. Stem ſhrubby, weak, climbing, round, ſmooth, branching. Leaflets uſually ſeven, broad lanceolate, quite entire, ſmooth, dark green, the end one larger and more pointed than the reſt. Peduncles few-flowered. Calycine ſegments capillary. Corolla white, odorous; tube long, cylindrical; border flat, ſhort, rounded. Anthers ſubſeſſile in the middle of the tube. Stigma above the tube, long, flattiſh, emarginate. Berry ſuperior, dicoccous. The border of the corolla is ſometimes only four-cleft [x].

We are not certain as to the native country of our common white Jaſmine. Linneus ſays India and Switzerland; but to the latter it is conſeſſedly exotic, although it be now accuſtomed to the climate, and grows ſpontaneouſly on the rocks, particularly about Chiavenna [y]. Probably it is wild in the Eaſt Indies.] Mr. Miller affirms, that it grows naturally in Malabar and ſeveral parts of India, yet has been long inured to our climate, ſo as to thrive and flower extremely well; but it never produces any fruit in England. Loureiro ſays, that it is wild about Canton in China. According to Parkinſon, it was thought to have been firſt brought to Spain out of Syria or thereabouts, and from Spain to us.—Gerarde cultivated this ſhrub, no leſs eſteemed for elegance than fragrance, in 1597 [z]. He ſays it was then common in moſt parts of England, being uſed for arbors, and to cover banquetting houſes in gardens; and that maſter Lyte would have it to grow wild among us, which however it did not, as far as he could underſtand.

The name of Jaſmine, has been corrupted into Jeſſamine, Gelſemine, Geſſemine, Jeſſima, Jeſſamy, and Geſſe.—In German it is Jaſmin, Jeſmin, Schaſmin, Schelſemine, Violreben. In Dutch, Jaſmyn. In Swediſh, Daniſh and French, Jaſmin. In Italian, Gelſomino. In Spaniſh Jazmin. In Portugueze, Jaſmim, Geſmim, Jaſmineiro. In Arabic, Jaſmin, Kajan.]

14. Spaniſh or Catalonian Jaſmine has much ſtronger branches than the Common White ſort, of which Linneus once ſuppoſed this to be only a variety. The leaflets are placed cloſer, and are of a lighter green, the ſide ones are obtuſe, but the odd one ends in an acute point. The flowers are axillary, on peduncles two inches long, each ſuſtaining three or four flowers, of a bluſh red on their outſide, but white within: the tube of the corolla is longer, the ſegments are obtuſe, twiſted at the mouth of the tube, and of a much thicker texture.

[Linneus remarks, that it reſembles the common ſort very much; but he gives the following diſtinctions: that the ſtem is ſtraight not ſcandent, the leaflets nearer to the ſtem more ovate, not ſmaller, the three outer ones confluent by the widened petiole, ſo that they cannot fall ſeparate.

It is a native of the Eaſt Indies; and Mr. Miller adds, of the iſland of Tobago, where the woods are full of it, and whence Mr. Robert Millar ſent him a great quantity. It appears from Parkinſon that it was cultivated here in 1629, when he ſays it was ſcarce made well acquainted with our Engliſh air. It came to us from Spain, and thence acquired the name of Spaniſh or Catalonian Jaſmine.

15. Stem ſhrubby, long, climbing, round, even, branched. Leaves unequally pinnate: leaflets an inch and half long, acuminate, quite entire, ſhining. Flowers pure white, but without ſmell, terminating, on many-flowered peduncles. Segments of the corolla oblong, blunt, uſually ſeven, but frequently five, ſix, or eight. Calycine ſegments as many, awl-ſhaped, erect. Berries two, ovate, with one arilled ſeed. It is allied to Nyctanthes glauca, (n. 2.) but has a habit approaching more to Jaſmine.—Native of Cochinchina, in hedges [z].

16. Branches obſcurely quadrangular, very ſmooth. Leaves two inches long, drawn into a very long point, extremely ſmooth, nerves vaniſhing above, almoſt

veinleſs

[r] Vahl. [s] Forſter. [b] Medicus. [t] Gaertner. [u] Hort. kew. [l] Willich & Medicus. [m] Hort. kew. [x] Hort. kew. [y] Loureiro, Haller. [z] Hort. kew. [a] Loureiro.

veinleſs and paler underneath. Petioles ſcarcely a quarter of an inch in length. Peduncles ſolitary, oppoſite, a little longer than the petioles, ſmooth, with two oppoſite, awl-ſhaped bractes in the middle. Calyx ſmooth, ſegments awl ſhaped, ſhorter by half than the tube of the corolla. Corolla an inch long, ſmooth with lanceolate ſegments.—Native of Java.

17. Shrubby, ſmooth. Branches round, climbing. Branchlets from each axil, ſolitary, oppoſite, quite ſimple, floriferous at top, the length of the leaves, ſpreading very much. Leaves petioled, extremely ſpreading, quite entire, flat, even, with the veins quite ſimple, two inches long and more. The leaves on the branchlets half an inch long, cordate-ovate. Panicle ſhort. Peduncles ſhort. Pedicels very ſhort. Bractes oppoſite at the baſe of the peduncles and calyx, linear, the length of the peduncles. Border of the calyx flat; ſegments ſix or ſeven, reflex, villoſe. Border of the corolla ſix or ſeven-cleft; clefts lanceolate, the length of the tube, which widens gradually [r].

Native of Bengal, climbing to the tops of trees, according to Koenig, who communicated it [r].]

PROPAGATION AND CULTURE.

1. The plants of Arabian Jaſmine are frequently imported from Italy by the Italian gardeners, who bring Orange trees for ſale; but theſe are always grafted upon ſtocks of the common Jaſmine, and not keeping pace in their growth with the ſtock, become very unſightly; beſides the ſtocks are very apt to ſhoot from the bottom, and if theſe ſhoots be not conſtantly rubbed off, they will ſtarve the graft. The beſt method therefore to obtain plants is by layers or cuttings. The former is the ſureſt method, for unleſs the cuttings be very carefully managed, they will not take root; and the ſtems being pliable may eaſily be brought down, and laid in pots filled with a ſoft loamy ſoil, plunged into a hot-bed of tan; if the branches be laid down in the ſpring, and carefully watered, they will put out roots by autumn, when they ſhould be cut from the old plants, and each tranſplanted into a ſeparate ſmall pot, and then plunged into the tan-bed, where they ſhould be ſhaded from the ſun till they have taken new root.

Cuttings may be planted from may to auguſt, in pots filled with the ſame earth, and plunged into a moderate hot-bed of tanner's bark. The pots ſhould be pretty large, to contain ten or twelve cuttings; they ſhould be cloſely covered with bell or hand-glaſſes to exclude the air, ſhaded from the ſun in the heat of the day, and gently refreſhed with water when the earth is dry: they will have taken root by auguſt, when they may be tranſplanted into ſeparate pots, and treated in the ſame way as the layers.

This plant may be preſerved in a moderate degree of warmth, but will thrive much better in the bark-ſtove, and produce a greater quantity of flowers; as the leaves continue all the year, it will make a fine appearance in the ſtove at all ſeaſons; and it will produce flowers great part of the year.

4. Azorian Jaſmine is pretty hardy, and requires only to be ſheltered from ſevere froſt. It is a green-houſe plant, but will live againſt a warm wall, if dung be laid to the roots, and a mat hung looſely over it in froſty weather. It is propagated in the ſame manner with n. 12. and requires the ſame management. It deſerves a place in every greenhouſe, for the leaves, being of a ſhining green, make a good appearance all the year; and the flowers, having a fine ſcent, and continuing long in ſucceſſion, render it very valuable.

10. Common Yellow Jaſmine was formerly more cultivated than now; for the flowers having no ſcent, few perſons regard them. It often produces ſo many ſuckers as to become troubleſome; and as it cannot be kept in order for ſtandards, it is ſeldom introduced into gardens at preſent. It is eaſily propagated by ſuckers or layers.

11. Italian or dwarf Yellow Jaſmine was brought over by the Italian gardeners with Orange trees. Theſe were grafted upon the common Yellow Jaſmine ſtocks. This is ſomewhat more tender than the preceding, but it will endure the cold of our ordinary winters, in a warm ſituation.

It may be propagated by laying down the tender branches; or by budding or inarching it upon the common Yellow ſort: the latter mode is preferable, as making hardier plants. It ſhould be planted againſt a warm wall, and in very ſevere winters will require to be ſheltered with mats. It muſt be dreſſed and pruned as the White Jaſmine, n. 13.

12. Yellow Indian Jaſmine is propagated either by ſeeds, or laying down the tender branches; if by ſeeds, which it ſometimes produces in England, make a moderate hot-bed in the ſpring, into which plunge ſome ſmall pots, filled with freſh light earth; and in a day or two after, when you find the earth in the pots warm, put your ſeeds therein; about four in each pot will be ſufficient, covering them about an inch thick with the ſame light earth, and obſerve to refreſh the pots with water as often as you ſhall perceive the earth dry; but do not give them too much at each time, which would be apt to rot the ſeeds.

In about ſix or eight weeks after ſowing, the plants will appear above ground, at which time it will be neceſſary to remove the pots into another freſh hot-bed, of a moderate temperature, in order to bring the plants forward; water them as often as is neceſſary, and in the great heat of the day the glaſſes ſhould be tilted pretty high, and ſhaded with mats, to prevent the plants from being ſcorched with heat. About the middle of may begin to harden them to the open air, by taking off the glaſſes when the weather is warm; but this muſt be done cautiouſly, for you ſhould not expoſe them to the open ſun in a very hot day at firſt, which would greatly injure them; but rather take off the glaſſes in warm cloudy weather at firſt, or in gentle ſhowers of rain, and ſo by degrees inure them to bear the ſun; and in june take the pots out of the hot-bed, and carry them to ſome well ſheltered ſituation, where they may remain until the beginning of october; at which time they muſt be carried into the green-houſe, obſerving to place them where they may enjoy as much free air as poſſible when the windows are opened, as alſo to be clear from the branches of other plants.

During the winter ſeaſon they will require to be often watered, but be careful not to give them too much at each time; and in march remove theſe plants each into a ſeparate pot, being careful not to take the earth from their roots; and if at this time you plunge them into a freſh moderate hot-bed, it will greatly facilitate their rooting again, and be of great ſervice to the plants; but when they are rooted, you muſt give them a great deal of air; for if you draw them too much, they will become weak in their ſtems, and incapable to ſupport their heads, which is a great defect in theſe trees.

You muſt alſo harden them to the open air, into which they ſhould be removed about the middle of may, obſerving, as was before directed, to place them in a ſituation that is defended from ſtrong winds, which are injurious to theſe plants, eſpecially while they are young. In winter houſe them as before, and continue the ſame care, with which they will thrive very faſt, and produce annually great quantities of flowers.

Theſe plants are pretty hardy, and will require no other care in winter, than only to defend them from hard froſts; nor do I know whether they would not live in the open air, if planted againſt a warm wall, ſince they are much hardier than the Spaniſh; but there is this difference between them, viz. theſe plants have large, thick, evergreen leaves, ſo that if they were covered with mats, as is directed for the Spaniſh Jaſmine, the leaves would rot and decay the ſhoots; but as theſe will only require to be covered in extreme froſt, if their roots are well mulched, and a mat or two looſely hung over them in ordinary froſts, it will be ſufficient; and theſe mats being either roolled up, or taken quite off in the day, there will be no great danger of their being hurt, which only can proceed from being too long cloſe covered.

In the ſpring theſe ſhould be pruned, when you ſhould

[r] Vahl. [r] Retz.

ſhould cut of all decayed branches; but you muſt not ſhorten any of the other branches, as is directed for the Spaniſh ſort, for the flowers of this kind are produced only at the extremity of the branches, which, if ſhortened, they would be cut off; and theſe growing of a more ligneous ſubſtance than the other, will not produce ſhoots ſtrong enough to flower the ſame year. If you would propagate this plant from layers, the ſhoots would be laid down in march; and if you give them a little cut at the joint, as is practiſed in laying Carnations, it will promote their rooting: obſerve to refreſh often with water, when the weather is dry; which, if carefully attended to, the plants will be rooted by the ſucceeding ſpring, fit to be tranſplanted, when they muſt be planted in pots filled with light earth, and managed as was before directed for the ſeedling plants.

This ſort is frequently propagated, by inarching the young ſhoots into ſtocks of the common yellow Jaſmine, but the plants ſo raiſed do not grow ſo ſtrong as thoſe which are upon their own ſtock; beſides, the common yellow Jaſmine is very apt to ſend out a great number of ſuckers from the root, which renders the plants unſightly; and if theſe ſuckers are not conſtantly taken off as they are produced, they will rob the plants of their nouriſhment.

13. Common white Jaſmine is eaſily propagated by laying down the branches, which will take root in one year, and may then be cut from the old plant, and planted where they are deſigned to remain: it may alſo be propagated by cuttings, which ſhould be planted early in the autumn, and if the winter ſhould prove ſevere, the ſurface of the ground between them ſhould be covered with tan, ſea-coal aſhes, or ſaw-duſt, which will prevent the froſt from penetrating deep into the ground, and thereby preſerve the cuttings; or where theſe are wanting, ſome Peas-haulm, or other light covering ſhould be laid over the cuttings in hard froſt; but theſe muſt be removed when the weather is mild, for they will keep off the air and occaſion damps, which often deſtroy them.

When theſe plants are removed, they ſhould be planted where they are deſigned to be continued, which ſhould be either againſt ſome wall, pale, or other fence, where the flexible branches may be ſupported; for although it is ſometimes planted as a ſtandard, and formed into a head, yet it will be very difficult to keep it in any handſome order; or if you do, you muſt cut off all the flowering branches; for the flowers are always produced at the extremity of the ſame year's ſhoots, which, if ſhortened before the flowers are blown, will entirely deprive the trees of flowers. *Theſe plants ſhould* be permitted to grow rude in the ſummer, for the reaſon before given; nor ſhould you prune and nail them until the middle or latter end of march, when the froſty weather is paſt; for if it ſhould prove ſharp froſty weather after their rude branches are pruned off, and the young ones are expoſed thereto, they are very often deſtroyed; and this plant being very backward in ſhooting, there will be no danger of hurting by late pruning.

There are two varieties of this with variegated leaves, one with white, and the other with yellow ſtripes, but the latter is the moſt common: theſe are propagated by budding them on the plain Jaſmine, and it often happens, that the buds do not take, but yet they have communicated their gilded miaſma to the plants; ſo that in a ſhort time after, many of the branches both above and below the places where the buds have been inſerted have been thoroughly tinctured, and the following year I have often found very diſtant branches, which had no other communication with thoſe which were budded than by the root, have been as compleatly tinged as any of the nearer branches, ſo that the juices muſt have deſcended into the root.

The two ſtriped ſorts ſhould be planted in a warm ſituation, eſpecially the white ſtriped; for they are much more tender than the plain, and are very ſubject to be deſtroyed by great froſts, if they are expoſed thereto; therefore the white ſtriped ſhould be planted to a ſouth or ſouth-weſt aſpect, and in very ſevere winters the branches ſhould be covered with mats or ſtraw, to prevent their being killed: the yellow ſtriped is not ſo tender, ſo may be planted againſt walls to eaſt or weſt aſpects; but theſe plants with variegated leaves, are not ſo much in eſteem as formerly.

14. This plant is propagated by budding or inarching it upon the common white Jaſmine, on which it takes very well, and is rendered hardier than thoſe which are upon their own ſtocks. But the plants of this kind being brought over from Italy every ſpring in ſo great plenty, they are ſeldom raiſed here: I ſhall therefore proceed to the management of ſuch plants as are uſually brought into England from the place above-mentioned, which are generally tied up in ſmall bunches, containing four plants, and their roots wrapped about with moſs, to preſerve them from drying; which, if it happen that the ſhip has a long paſſage, will often occaſion them to puſh out ſtrong ſhoots from their roots, which muſt always be taken off before they are planted, otherwiſe they will exhauſt the whole nouriſhment of the plant, and deſtroy the graft.

In the making choice of theſe plants, you ſhould carefully obſerve if their grafts are alive, and in good health: for if they are brown and ſhrunk, they will not puſh out, ſo that there will be only the ſtock left, which is of the common ſort.

When you receive theſe plants, you muſt clear the roots of the moſs, and all decayed branches ſhould be taken off; then place their roots into a pot or tub of water, which ſhould be ſet in the green-houſe, or ſome other room, where it may be ſcreened from the cold; in this ſituation they may continue two days, after which you muſt prune off all the dry roots, and cut down the branches within four inches of the place where they were grafted, and plant them into pots filled with freſh light earth; then plunge the pots into a moderate hot-bed of tanners bark, obſerving to water and ſhade them, as the heat of the ſeaſon may require. In about a month or ſix weeks after they will begin to ſhoot, when you muſt carefully rub off all ſuch as are produced from the ſtock below the graft, and you muſt now let them have a great ſhare of air, by raiſing the glaſſes in the heat of the day; and as the ſhoots extend, they ſhould be topped, to ſtrengthen them, and by degrees ſhould be hardened to endure the open air, into which they ſhould be removed the beginning of june, but muſt have a warm ſituation the firſt ſummer; for if they are too much expoſed to the winds, they will make but indifferent progreſs, being rendered ſomewhat tender by the hot-bed. If the ſummer proves warm, and the trees have ſucceeded well, they will produce ſome flowers in the autumn following, though they will be few in number, and not near ſo ſtrong as they will be the ſucceeding years, when the trees are ſtronger and have better roots.

Theſe plants are commonly preſerved in green-houſes, with Oranges, Myrtles, &c. and during the winter ſeaſon, will require to be frequently watered; which ſhould be performed ſparingly each time, eſpecially in cold weather, for too much wet at that ſeaſon will be apt to rot the fibres of their roots; they ſhould alſo have a great ſhare of freſh air when the weather will permit, for which purpoſe they ſhould be placed in the cooleſt part of the green-houſe, among plants that are hardy, where the windows may be opened every day, except in froſty weather; nor ſhould they be crowded too cloſe among other plants, which often occaſions the tender part of their ſhoots to grow mouldy and decay. In april the ſhoots of theſe plants ſhould be ſhortened down to four eyes, and all the weak branches ſhould be cut off; and if you have the conveniency of a glaſs-ſtove, or a deep frame, to place the pots in at that ſeaſon, to draw them out again, it will be of greater ſervice in forwarding their flowering; yet ſtill you ſhould be careful not to force them too much; and as ſoon as they have made ſhoots three or four inches long, the glaſſes ſhould be opened in the day time, that the plants may, by degrees, be inured to the open air, into which they ſhould be removed by the latter end of may, or the beginning of june; other-

wise their flowers will not be so fair, nor continue so long. If the autumn prove favourable, these plants will continue to produce fresh flowers until november; and sometimes when they are strong they will continue flowering later; but then they must have a great share of air when the weather is mild and will admit of it, otherwise the flower-buds will grow mouldy and decay. But notwithstanding most people preserve these plants in green-houses, yet they will endure the cold of our ordinary winters in the open air, if planted against a warm wall, and covered with mats in frosty weather; they will also produce ten times as many flowers in one season as those kept in pots, and the flowers will likewise be much larger; but they should not be planted abroad till they have acquired strength, so that it will be necessary to keep them in pots three or four years, whereby they may be sheltered from the frost in winter; and when they are planted against the wall, which should be in may, that they may take good root in the ground before the succeeding winter, you must turn them out of the pots, preserving the earth to their roots; and having made holes in the border where they are to be planted, you should place them therein, with their stems close to the wall; then fill up the holes round their roots with good, fresh, rich earth, and give them some water to settle the ground about them, and nail up their shoots to the wall, shortening such of them as are very long, that they may push out new shoots below to furnish the wall, continuing to nail up all the shoots as they are produced. In the middle, or toward the latter end of july, they will begin to flower, and continue to produce new flowers until the frost prevents them; which, when you observe, you should carefully cut off all the tops of such shoots as have buds formed upon them, as also those which have the remains of faded flowers left: for if these are suffered to remain on, they will soon grow mouldy, especially when the trees are covered, and thereby infect many of the tender branches, which will greatly injure the trees.

Toward the middle of november, if the weather proves cold and the nights frosty, you must begin to cover your trees with mats, which should be nailed over them pretty close; but this should be done when the trees are perfectly dry, otherwise the wet being lodged upon the branches, will often cause a mouldiness upon them, and the air being excluded therefrom, will rot them in a short time: it will also be very necessary to take off the mats as soon as the weather will permit, to prevent this mouldiness, and only keep them close covered in frosty weather, and in the nights; at which time you should also lay some mulch upon the surface of the ground about their roots, and fasten some bands of hay about their stems, to guard them from the frost: and in very severe weather, you should add a double or treble covering of mats over the trees; by which method, carefully performed, you may preserve them through the hardest winters. In the spring, as the weather is warmer, you should by degrees take off the covering; but you should be careful not to expose them too soon to the open air, as also to guard them against the morning frosts and dry easterly winds, which often reign in march, to the no small destruction of tender plants if they are exposed thereto; nor should you quite remove your covering until the middle of april, when the season is settled; at which time you should prune the trees, cutting out all decayed and weak branches, shortening the strong ones to about two feet long, which will cause them to shoot strong, and produce many flowers.

There is a variety of this with semi-double flowers, which is at present more rare in England, and only to be found in some curious gardens; though in Italy it is pretty common, from whence it is sometimes brought over amongst the single; the flowers of this kind have only two rows of leaves, so that it is rather cultivated for its curiosity, than for any extraordinary beauty in the flowers. This may be propagated by budding it upon the common white Jasmine, as has been directed for the single, and must be treated in the same manner.

[JASMINUM. See *Cestrum, Chiococca, Citharexylum, Ehretia, Guaiacum, Ipomœa, Jussiæa, Ixora, Lantana, Nyctanthes, Psychotria, Volkameria.*]

Nat. order of *Tricoccæ. Euphorbiæ.* Juss.

GENERIC CHARACTER.

* *Male Flowers.*

CAL. *Perianth* scarcely manifest.

COR. one petalled, funnel form. *Tube* very short. *Border* five-parted: *divisions* roundish, spreading, convex, concave beneath.

STAM. *Filaments* ten, awl-shaped, approximated in the middle; the five alternate ones shorter, upright, shorter than the corolla. *Anthers* roundish, versatile.

PIST. A weak rudiment, latent in the bottom of the flower.

* *Female Flowers* in the same umbel with the males.

CAL. none.

COR. five-petalled, rosaceous,

PIST. *Germ* roundish, three-furrowed. *Styles* three, bifid. *Stigmas* simple.

PER. *Capsule* roundish, tricoccous, three-celled, cells bivalve.

SEEDS solitary, roundish.

OBS. J. urens *has nine upright stamens, of which the three interior are longer than the rest, to which there are as many bristles correspond, each placed on each of these filaments near the base.*

Some species in the male flowers have a five-cleft calyx and a five-petalled corolla.

At present ten stamens are ascribed to J. urens.

Syst. Veget. 723. R.

ESSENTIAL CHARACTER.

MALE. *Cal.* none. *Cor.* one-petalled, funnel-form. *Stam.* ten, alternately longer and shorter.

FEM. *Cal.* none. *Cor.* five-petalled, spreading. *Styles* three, bifid. *Capf.* three-celled. *Seed* one.

SPECIES.

1. Jatropha gossypifolia. *Cotton-leaved Physic-nut* or *wild Cassada.*

Lin. spec. 1428. *Reich.* 4. 190. *Swartz obs.* 366. *Brown. jam.* 348. 2. *Vahl. symb.* 1. 78.

J. staphisagrifolia. *Mill. dict. n.* 9.

Ricinus minor, staphisagriæ folio, flore pentapetalo purpureo. *Sloan. jam.* 1. 129. *t.* 84.

Leaves ternate elliptic quite entire, hoary underneath, on long petioles.

DESCRIPTIONS, &c.

1. Stem from two to three feet high, herbaceous, branched, smooth. Branches subdivided, round, beset at the base with branched glanduliferous cilias or briftles. Leaves digitate, veined, tender, often three-lobed; lobes acute, serrate, toothed and ciliate, cilias glandular. Common peduncle terminating; partial cymed, bifid; male flowers very copious, females solitary, in the forks of the peduncles. In the males, calyx five-leaved; leaflets ovate, acute, ciliate. Corolla deeply five-parted, dark purple; segments ovate. At the base of the stamens are five roundish nectareous glands. Filaments ten to twelve, united up to the middle, the length of the corolla: anthers bifid ovate. The females have the calyx and corolla as in the males; but without any nectary. Germ roundish, obtusely three-cornered: style trifid from the base; stigmas dilated, bifid. Capsule ovate, three-cornered, retuse[a].

Native of the West Indian islands; very common in most parts of Jamaica, where the soil is dry and gravelly, and the situation warm. It grows most luxuriantly about houses, where the ground is warmed with dung, and rises in such places, to the height of three feet and a half or more. It is a very beneficial plant in every plantation where they raise any quantity of poultry, which are very fond of the seeds. A decoction of the leaves is sometimes used as a purgative in the dry belly-ach[b]. Hence it is called Belly-ach weed. Brown names it Wild Cassava or Cassadar. It was cultivated by Mr. Miller before 1759.

2. Stem herbaceous, erect, a foot high, pubescent. Leaves wedge-shaped at the base, smooth, glaucous, almost veinless, nerved and villose underneath; segments oblong, acuminate; teeth sharp, unequal, somewhat glandular at the end. Petioles subvillose, longer than the leaves, without glandular hairs. Stipules solitary on each side divided into four or five bristles; bristles unequal, glandular at top, simple, seldom branched. Peduncles towards the top, opposite to the leaves, three inches long, the height of the stem. Corymbs dichotomous: female flowers in the divisions, on short pedicels. Bractes lanceolate-awl-shaped. Calyx permanent, five-leaved: leaflets lanceolate, ciliate. Petals of the female flower the length of the calyx, ovate. Filaments alternately shorter: anthers eight. Germ three-sided: style one: stigmas three. Capsule almost the size of a hazel nut, muricated. Seed the size of a pea, in shape like that of Ricinus.

It is distinguished from the preceding at first sight by its glaucous hue: but besides this, it differs in having the leaves produced at the base but not transverse; the lobes oblong, sharply serrate, not ovate and ciliate-glandular, as in that; and the petioles naked, without branched glandular hairs.—Native of Arabia and the East Indies.

3. Branches round, smooth, with a purple wrinkled bark, glaucous at top. Leaves alternate, very smooth, half an inch long; lobes oblong, very blunt, widened at top, the side ones smaller, narrower, having sometimes a small lobe on the outer side of the base. Petiole a little shorter than the leaf, round. Prickles on each side solitary at the base of the petiole instead of stipules, of the same colour with the bark, awl-shaped, shorter than the petiole. Corymbs dichotomous. The female flower sessile in the divisions. Calyx five-leaved. Corolla five-petalled.

4. This is a shrub with round branches, the bark at bottom brown and chinky, glaucous above. Leaves subpetioled, alternate, blunt, ending in a stiff dagger-point, very smooth, sometimes variegated on the upper surface, two inches long. Stipules in pairs on each side by the side of the petiole, placed on a callus, awl-shaped, stiff, often longer than the petiole, divaricating, permanent, the lower like prickles. Corymbs axillary, shorter than the leaf. Bractes lanceolate, keeled. Calyx five-parted, with oblong segments. Corolla five-petalled: petals oblong. Anthers eight. Capsule smooth, oblong. It varies with broader and narrower leaves. This is different from Croton variegatum; that having the flowers in spikes, and no stipules.

5. This is a branching shrub, with a wrinkled, villose bark. Leaves alternate, kidney-form, soft; lobes rounded, unequally toothletted, with brown glands. Petiole the length of the leaf, villose, spreading. There are several glands by the sides of the petiole and in the axils.

These, though they are furnished with a calyx, are distinct from the genus Croton, the flowers in that being in spikes[c].

[a] Swartz. [b] Browne. [c] Vahl.

6. This is a tree with alternate, ovate or ovate-cordate leaves, with ſome ſcarcely conſpicuous angles, or one or two teeth, acute like thoſe of the Hernandia, but not peltate. Petioles the length of the leaves, with two glands at top where they enter the leaves. Corymb terminating, variouſly dichotomous. Female flowers on ſhorter peduncles in the primary diviſions, with a roundiſh germ, and four awl-ſhaped ſtyles. The males, which are numerous, have a one-leafed, bell-ſhaped, two-parted calyx, with ovate, concave ſegments. Petals five, lanceolate, bluntiſh, patulous, twice as long as the calyx. Filaments numerous, awl-ſhaped, collected into a head, the length of the calyx, the outer ones ſhorter: anthers cordate. It has the ſame appearance with the other ſpecies, but differs in the calyx, the number of petals and piſtils [a]. Now that is better known, it is found that it ought to conſtitute a diſtinct genus [b].

Native of the Molucca iſlands and Ceylon.

7. Native of Jamaica [c].

8. Stem a fathom in height, or according to Browne ſeldom more than ſeven or eight feet, ſuffruteſcent, round, ſmooth and branched. Leaves five-angled, the angles at the baſe rounded, the reſt acute. Flowers in terminating cymes; peduncles alternate, upright, many-flowered; flowers almoſt aggregate, on very ſhort pedicels. Males copious; females ſeſſile, fewer, ſolitary in the middle of the cyme. In the males the calyx is five-leaved, with ovate, convex leaflets. Corolla five-parted to the baſe, pale yellow. Filaments ten to fourteen, connected from the baſe to the middle: anthers oblong, upright. Glands five, at the baſe of the filaments. The females have the calyx and corolla as in the male; the latter green and larger. Germ roundiſh, bluntly three cornered: ſtyle three-parted above the middle, with bifid tips: ſtigmas blunt [d]. Capſule oblong, obtuſely-three-cornered, large, when ripe wrinkled and rugged on the outſide; the rind thick and coriaceous: the three grains or cells papery, whitiſh, two-valved: receptacle central, columnar, ſleader, thickened at top into a flatted fungous head. Seeds ſolitary, large, ovate-oblong, convex on one ſide, on the other very obſcurely angular, inſomuch that they are almoſt cylindric, produced at the tip into a hollow dagger-point, in which there is a white fungous umbilicus; they are black with minute chinks, and rough on the touch [e].

Native of South America and the iſlands in the Weſt Indies. Browne ſays it is very common in all the ſugar colonies, and cultivated frequently in incloſures, but dies after a few years. The leaves are much uſed in reſolutive baths and fomentations, and the ſeeds ſometimes as a purgative, but they operate very violently, and are therefore now but little uſed. Gærtner ſuggeſts that it was firſt obſerved by Boyle, that the fruit might be eaten with ſafety, if the embryo were taken out.

It was cultivated in 1731, by Mr. Miller [f].

9. This grows generally to the height of five, ſix, or ſeven feet, with a very ſmooth, ſuffruteſcent ſtem, and ſpreading branches. Stipules briſtle-ſhaped, multifid, at the baſe of the branches and petioles. Leaves alternate, ſubpeltate, multifid; the diviſions pinnate with the odd leaflet longer, ſmooth but whitiſh underneath. Peduncles terminating, very long, round, thick, very ſmooth, ſubdivided. Pedicels coloured, in corymbs. Flowers ſmall, red. Males very numerous. Females ſolitary, ſubſeſſile.—In the former, calyx five-cleft, coloured. Petals five ovate, entire. Nectary five-parted, ſurrounding the ſtamens. Filaments eight, red, united at the baſe: anthers ovate, yellow. In the latter, calyx five-parted, coloured. Corolla five-petalled: petals ovate, red. Germ three-cornered, green: ſtyles three, ſhorter, red, bifid at top: ſtigmas blunt. Capſule, larger, oblong, growing yellow as it ripens. Seeds ſolitary, round [g].

It is now very common in moſt of the iſlands in the Weſt Indies, but was introduced from the continent firſt into the French iſlands, whence it is called in the Britiſh iſlands French Phyſic-nut. [It is much cultivated in Jamaica, and forms no ſmall ornament in their flower-gardens, with its large bunches of beautiful red flowers [h]. The whole plant diſtils a tenacious watery liquor [i]. The ſeeds are purgative, but ſo violent in their operation that they are now rarely adminiſtered, though formerly, they were almoſt the only purgative medicine uſed among the Spaniards [k].

It was cultivated in 1696, in the royal garden at Hampton Court; and flowers from june to auguſt [l].

10. The Caſſava ſhoots from a tough, branched, woody root, whoſe ſlender collateral fibres ſwell into thoſe fleſhy conic maſſes for which the plant is cultivated; and riſes by a ſlender woody knotted ſtalk, to the height of four, five, or ſix feet, ſometimes more [m].] Leaves alternate, ſmooth, on long petioles, ſeven-lobed; lobes narrow at the baſe, growing broader till within an inch and half of the top, where they diminiſh to an acute point; the three middle lobes are about ſix inches long, and two broad where broadeſt; the two next are about an inch ſhorter, and the two outſide lobes are not more than three inches long: the middle lobes are ſituated on each ſide near the top, but the two outer are entire. The flowers are produced in umbels at the top of the ſtalks, ſome male and others female; petals five, ſpreading: in the male flowers ſtamens ten, united; in the females, germ round with three furrows in the centre: ſtyles three, two diſtant, and one riſing between them ſhorter, all crowned by a ſingle ſtigma. Capſule roundiſh.

[Native of South America. Pere Rochon ſays that it was tranſported into the Iſle of France from Braſil. This plant which formerly ſupplied the greateſt part of the ſuſtenance of the native Indians, is now raiſed in moſt parts of America, and generally conſidered as a very beneficial vegetable, yielding an agreeable wholeſome food; and this, with its eaſy growth and hardy nature, recommends it every where.

It grows to perfection in about eight months, but the roots will remain a conſiderable time in the ground uninjured. They are generally dug up as occaſion requires, and prepared for uſe in the following manner: being firſt well waſhed and ſcraped, then rubbed to a pulpy farina on iron graters, they are put into ſtrong linen or palmetto bags, and placed in a convenient preſs, until the juice is entirely expreſſed: the farina is then taken out and ſpread in the ſun for ſome time, pounded in large wooden mortars, run through coarſe ſieves, and afterwards baked on convenient irons. Theſe are placed over proper fires, and when hot beſtowed with the ſifted meal to whatever ſize or thickneſs people pleaſe to have the cakes made: this agglutinates as it heats, grows gradually harder, and when thoroughly baked, is a wholeſome well-taſted bread. *Tapioca* is alſo prepared from this root.

The juice of the root is ſweetiſh, but more or leſs of a deleterious nature both freſh and in the putrid ſtate, though it hardly retains any thing of this quality whilſt it ferments [n]. The milky juice ſwallowed, or the root eaten without preparation, brings on convulſions, and occaſions violent retching and purging: it acts only on the nervous ſyſtem, and produces no inflammation in the ſtomach; but the ſtomach of a man or other animal poiſoned by it appears to be contracted one half [o].

However violent the rough juice may be found immediately after it is expreſſed, it is certain that the roots are daily eaten by Hogs without prejudice; and a little mint-water and ſalt of wormwood will calm the moſt violent ſymptoms that ariſe on taking it, and prevent all bad conſequences, even in the human ſpecies, if it be but timely adminiſtered.

What is expreſſed from the farina is frequently preſerved and prepared for many economic uſes: in boiling it throws up a thick viſcid ſcum, which is always thrown away, and the remaining fluid is ſometimes diluted and kept for common drink; and is thought to reſemble whey very much in that ſtate. Some uſe it in ſauces for fiſh and many other ſorts of food; purpoſes for which it was employed by the native In-

[a] Linn. ſeyl. [b] Swartz obſ. [c] Swartz prodr. [d] Swartz. [e] Gærtner. [f] Hort. kew. [g] Swartz. [h] Browne. [i] Swartz. [k] Browne. [l] Hort. kew. [m] Browne. [n] Ibid. [o] Rochon's madag. introd. 23.

dians,

dians, long before any European had landed in thoſe parts of the world.

The farina whilſt yet impregnated with the juice, makes an excellent ſalve, which ſeldom fails to clean and heal the moſt deſperate ſores: where theſe are very foul, or the parts too much relaxed, it is ſometimes mixed with a few pounded tobacco leaves; and has been often found effectual, where common ointments have not had the leaſt force: it is alſo uſed by way of poultice, and is an excellent reſolutive [a].

In Madagaſcar Caſſava is the ordinary food of the Blacks, and the French call it Madagaſcar Bread. In the Weſt Indies this plant is called Caſſava, Caſſada or Caſſadar. In Braſil Mandihoca, Manuba, Manduba: whence we have the name Manihot; and in French Manhiot, Magnoc, Manioc, Manioque; in Potugueze Mandioca; in Dutch Maniok; in German Manihot, Maniok. The Caraibees call it Yuka or Juca; which name is adopted in Germany, and by the Spaniards, who call it Yucca de Caſſabe. The Germans and Dutch have alſo adopted the Weſt Indian name, as well as the Engliſh.—At Rio di Janeiro they call the flour or meal of the Caſſava root, Farinha di Pao; which may not improperly, be tranſlated, Powder of poſt [b].

It was cultivated here in 1739, by Mr. Miller, and flowers in july and auguſt [c].

11. This is an upright ſhrub, quite ſmooth all over, abounding in an aqueous juice, that is ſomewhat clammy, and has the ſmell of walnut leaves. In cloſe woods it frequently riſes with a weak, unbranched, rod-like ſtem to the height of twenty feet, and it retains this habit in the European ſtoves: among other ſhrubs in open places it is commonly no more than ſix feet high, and approaches very near to the figure of the preceding ſort, from which Linneus ſeems to think this is hardly ſpecifically different. In the ruined walls of the fortreſs of Boca Chica it is become a ſort of tree, eight feet high, with a ſtraight trunk four inches in diameter, and with a pretty head. Loureiro deſcribes it, as only four feet high, with a ſtraight, unbranched, unarmed ſtem.—Roots very tuberous, like thoſe of Aſphodel, in bundles; the tubers ovate-oblong, acute, white within and without, three inches long, with a ſweetiſh hot taſte. Leaves large, elegant, palmate-digitate; lobes five, (about nine, according to Loureiro) oblong, acuminate, contracted in the middle on both ſides by a very large ſinus; the outer ones frequently quite entire; (lanceolate, unequal, quite entire or ſometimes ſinuated, L.) petiole half a foot in length. Racemes looſe, bearing a few female flowers below many males. Corolla yelloviſh and browniſh green. Filaments before fecundation quite upright, but after that bent in various directions. The fruit is covered with a fleſhy green pellicle, marked with ſix white ſtreaks, and ſhining very much: it is then globular and more than half an inch in diameter; but this dries up and falls off, and then the capſule remains three-lobed on the ſides. But this is more or leſs the caſe in the other ſpecies of this genus, Croton and Acalypha. The ſeeds are ſhining, ſubovate, green or aſh-coloured.

Native of South America: common about Carthagena, flowering almoſt the whole year [d]: alſo of China, according to Loureiro, who adds, that it is uſed, not raw but boiled, as a reſolutive, like the preceding.]

12. This has a thick, ſwelling, fleſhy root, from which ariſes an herbaceous ſtalk as big as a man's thumb, four or five feet high, and dividing into ſeveral branches; theſe are very cloſely armed with long brown ſpines, the foot-ſtalks of the leaves are ſix or ſeven inches long, which are alſo armed with ſpines, but not ſo cloſely, nor are the ſpines ſo long as thoſe on the ſtalk and branches: the leaves are deeply cut into five lobes, which are jagged deeply on their ſides, and the nerves are armed with ſtinging ſpines: the flowers are produced in umbels at the top of the branches, ſtanding upon long naked peduncles; they are of a pure white colour: the male flowers appear firſt, they are five-petalled, forming a ſhort tube at bottom, and ſpreading open flat above; the ſtamens are the length of the tube, and fill it up at the mouth: the female flowers are ſmaller, but of the ſame ſhape, with an ovate three-cornered germ.

[According to Jacquin, the leaves are half-three-lobed, and cordate at the baſe. Corolla naked; the male flowers one-petalled, the females five-petalled. Stamens ten.

Native of Braſil.] Mr. Miller ſays, it was found at Carthagena in New Spain by Mr. Robert Millar, who ſent the ſeeds to England, which ſucceeded in ſeveral curious gardens. [But according to the catalogue of the Royal garden at Kew, it had been introduced before by Mr. Bentinck in 1690. It flowers from may to july.]

Mr. Miller has another ſort, found by Dr. Houſtoun at La Vera Cruz, where it was planted for ornament. Having leaves divided like the common Wolfsbane, he names it Jatropha aconitifolia. It riſes with a ſtrong, brittle, woody ſtalk, ten or twelve feet high, covered with a gray bark, and dividing into many branches. The leaves are armed with ſmall ſtinging ſpines like thoſe of the Nettle. At the ends of the branches come out the flower-ſtalks, which are five or ſix inches long, and ſuſtain an umbel of white flowers. The males are one-petalled, and have a pretty long tube, divided at top into five ſegments: the females expand in form of a roſe, and are ſucceeded by a globular, prickly, tricoccous fruit. [It is probably a variety of the urens.]

13. This is an annual plant riſing with an herbaceous ſtalk about a foot high, dividing into two or three branches. Leaves alternate on long foot-ſtalks; lobes oblong, ſlightly ſinuated, ending in acute points. The whole plant is cloſely armed with long, briſtly, ſtinging ſpines. The flowers grow in an umbel at the ends of the branches; they are ſmall, of a dirty white colour: the females are ſucceeded by ovate, three-lobed capſules, covered with the ſame ſpines as the plant.

[Native of La Vera Cruz.

14. The tree yielding that reſin which is now commonly known under the name of Elaſtic Gum is ſuppoſed to be of this genus; but there are ſeveral others which yield a ſimilar juice, as Ficus indica, Cecropia peltata, &c.[f] Schreber placed it in a new genus, *Siphonia*.

It is a native of Guiana, of Quito and Braſil, particularly in Para, where it is called Maſſaradub. The Indians by an inciſion in the bark extract a viſcid white ſubſtance, like that which iſſues from the fig-tree; they receive it into earthen moulds, to make rings, bracelets, girdles, ſyringes, hats, boots, flambeaux, figures of animals, &c. Abbé Rochon ſays that the inhabitants of Madagaſcar alſo made flambeaux of it, which burn without wicks, and afford them a very good light when they go out to fiſh in the night time; that ſurgery has derived ſome benefit from it, as it ſerves to make excellent bandages; and that in a ſtate of ſolution, it is very proper for coating over ſilk, to render it impervious to air or water. It has the extenſibility of leather, with a very conſiderable elaſticity. Spirit of wine makes no impreſſion on this ſubſtance, but it diſſolves in ether and linſeed oil, or in nut oil digeſted gently in a ſand bath: there are alſo other fat and oily ſubſtances which affect it very ſenſibly. The Chineſe have been long acquainted with the art of diſſolving it, and of giving it various colours.

Abbé Rochon deſcribes the tree which yields the elaſtic gum in Madagaſcar as twenty feet high, the leaves eight inches long and two inches broad, the fruit reſembling a round fig and full of ſmall ſeeds. We may conclude therefore that this three is the Ficus indica; certainly not a Jatropha. The coagulated juice however is of the ſame nature.

The firſt account which we have of the elaſtic gum or reſin, or Caoutchouc, as it is called by the Indians to the S. E. of Quito, is in a memoir by Monſ. de la Condamine in the Memoirs of the French Academy

[a] Browne. [b] Hawkſw. voy. 2. 53. [c] Hort. kew. [d] Jacquin. [f] Linn. ſuppl.

for 1751, and in his relation of the river of Amazons in 1745. The tree which yields this ſubſtance grows along the banks of this river, and is very common in the foreſts of the province of Emeralds to the north of Quito, where it is called *Hbeve*, and whence Aublet has taken his generic name.

The tree is deſcribed as very lofty and ſtraight, and quite naked up to the head, which is very ſmall; the trunk of the largeſt is only about two feet in diameter. The foliage is not unlike that of the Caſſava (n. 10.). The fruit is triangular, incloſing three ſeeds. Theſe ſeeds or kernels, peeled and boiled in water, yield a thick oil, which the Indians uſe as butter with their food. The wood of the tree is light and fit for maſts.

Monſ. Freſnau likewiſe, about the year 1746, diſcovered the ſame tree at Cayenne. Whatever is made of this ſubſtance muſt be done on the ſpot, becauſe it thickens and dries very faſt. Warm water will ſoften and render it ſupple; it is ſenſible to the leaſt degree of froſt, but the heat of the ſun does not make any impreſſion upon it.]

PROPAGATION AND CULTURE.

All theſe plants being natives of the warm parts of America, are too tender to thrive in the open air in England. The firſt ſort is cultivated in the Weſt Indies for food, where it is propagated by cutting the ſtalks into lengths of ſeven or eight inches, which, when planted, put out roots.

The other ſorts are eaſily propagated by ſeeds, which ſhould be ſown on a good hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſmall pot filled with light earth, and then plunged into a freſh hot-bed of tanners bark, carefully ſhading them till they have taken freſh root; after which they muſt be treated in the ſame manner as other tender plants from hot countries, admitting freſh air to them daily, in proportion to the warmth of the ſeaſon; but as many of the ſorts have ſucculent ſtalks, ſome of which have a milky juice, they ſhould have but little water given them, for they are ſoon deſtroyed by wet.

The thirteenth ſort is an annual plant; if the ſeeds are ſown early in the ſpring, and the plants are brought forward, they will perfect their ſeeds the ſame year; but the other ſorts are perennial, ſo do not flower till the ſecond or third year; therefore the plants ſhould be plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain, giving them a large ſhare of air in warm weather; but in winter they muſt be tenderly treated, and in that ſeaſon muſt have very little water. With this management the plants will continue ſeveral years, and produce their flowers, and frequently perfect their ſeeds in England.

[10. The Caſſava thrives beſt in the Weſt Indies, in a free mixed ſoil, is propagated by the bud or gem, and is generally cultivated in the following manner. The ground is firſt cleared, and hoed up into ſhallow holes, of about ten or twelve inches ſquare, and ſeldom above three or four inches in depth. When they intend to plant, they provide a ſufficient number of full-grown ſtems, and cut them into junks, of about ſix or ſeven inches length, as far as they find them tough and woody, and well furniſhed with prominent, well-grown, hardy buds: of theſe they lay one or two in every hole, and cover them over with mould from the adjoining bank; but care muſt be taken to keep the ground clean, until the plants riſe to a ſufficient height to cover the mould and to prevent the growth of all weaker weeds*.

DESCRIPTIONS, &c.

1. This is a low ſhrubby plant, which ſeldom riſes above a foot and half high, having many ſlender branches, which ſpread on every ſide, and fall towards the ground if they are not ſupported. Theſe branches are well furniſhed towards their extremity with leaves, which continue green all the year; and in ſummer the flowers are produced at the end of the ſhoots; they are white and grow in an umbel, continue long in beauty, and being ſucceeded by others, the plants are rarely deſtitute of them from the end of auguſt to the beginning of june, which renders this plant valuable.

There is a variety with ſtriped leaves.

[It is a native of Perſia and Sicily, and was cultivated in the Oxford garden in 1680[a].]

2. This is of humbler growth than the firſt, ſeldom riſing more than ſix or eight inches high, nor do the branches grow woody, but are rather herbaceous. The leaves continue green through the year, and the flowers are of as long duration as thoſe of the firſt ſort.

[Native of the iſland of Candia on rocky ground. Cultivated in the botanic garden at Chelſea in 1739, flowering from april to june[b].

3. Root horizontal, with many fibres. Stems many, depreſſed, brown, round, naked, commonly, ſimple, not at all ſtriated. Leaves ſome oblong others lanceolate, all entire, alternate, ſeſſile, ſmooth, more or leſs ſpreading, many eſpecially about the middle of each branchlet. Flowers in terminating corymbs. Calycine leaflets oblong, almoſt equal, membranaceous and whitiſh at the tip. Corolla white; the two outer petals double the ſize of the others, from a ſhorter and ſlender claw ſpreading out into an oblong entire obtuſe border. The four longer filaments are red, and grow thicker above the middle. There are two elliptic green glands between the ſhorter filaments and the germ, which is elliptic; the ſtyle is ſhort, and the ſtigma is yellowiſh and papilloſe. Silicle (or rather capſule) rufeſcent, flattiſh on one ſide, ſlightly convex on the other, and marked with tranſverſe branched wrinkles. Seed ſingle in each cell, ovate, rufous, ſlightly compreſſed, faſtened by its proper pedicel to the upper part of the partition.

The ſeed-leaves are ovate, elliptic, ſmooth. The ſeeds germinate in fourteen or ſixteen days. It flowers the ſecond year, but all the ſeeds do not arrive at maturity. It has no ſmell: but the ſame taſte as *Lepidium*. It agrees with the two preceding ſorts in having fruteſcent ſtems, ſmooth leaves, and white flowers; but differs from the *ſempervirens* in having the ſtems not upright, the branches neither rigid nor ſtriated, and the leaves acute; from the *ſemperflorens* in the leaves not appearing in winter, and in the ſtems being flexile, more ſlender, and warted by the fallen leaves.

The ſeed-veſſel differs no otherwiſe from a capſule than in having deciduous valves, and it has only a ſingle ſeed in each of the two cells[c].

Native of Piedmont, about Strop, above Tende in the high mountains between Briga and Carlin, and above Frabroſa[d].

4. Stems many, thick, green, ſtriated, aſcending, from a foot to eighteen inches in length, divided into ſeveral branches. Leaves alternate, gradually widening from a narrow baſe, ending in a blunt point, thick, ſmooth, veinleſs except in the middle, dark green above; ſomewhat paler underneath. Flowers terminating in corymbs, at firſt white, afterwards pale purple, without ſcent; the two outer petals broader and longer. Anthers oblong, at firſt yellow but turning brown or duſky purple. Calycine leaflets green with purple edges. Seeds broadiſh, flatted, browniſh.

The ſtems are rigid and woody; the leaves in the wild plant are ſmaller and more bluntly toothed than in the cultivated one[e].

[a] Hort. kew. [b] Ibid. [c] Scopoli. [d] Allioni. [e] Dillenius.

The

The flowers bear some resemblance to those of the common Candy-tuft, (n. 8.) but when they blow in perfection they are usually twice as large: hence they are highly ornamental in the greenhouse, early in the spring, which is the time of their appearing[f].

It is nearly allied to the first species, but it is less shrubby and woody, the leaves are toothed towards the end, and the flowers are in larger corymbs.

5. rotundifolia (n. 6.) is a smaller and less robust plant, the leaves smaller and rounder, the flowers and silicles also smaller, the latter rounder, not emarginate[g].

Native of Spain. Cultivated in 1732 at Eltham by James Sherard, M. D.[h]

5. Root woody, hard, twisted and large. Stems diffused, numerous, branched at the base, scarred with fallen branches and leaves, three or four inches high. Leaves clustered, very narrow, almost cylindrical, succulent, smooth, sessile, diminishing in length as they are higher on the stem, and ciliate on the edge; the lower ones spreading and reflex, the upper approximating to the stem and fewer. The stems and branches are almost naked at top, and terminate in a corymb of white or purple flowers: in the progress of the inflorescence the corymb becomes a raceme. Calycine leaflets ovate, white at the edge, the same length with the claws of the corolla. Petals almost linear, only the end is broader, crenulate but not emarginate, the two upper ones double the length of the two others or more. Filaments purple at top. Silicle large, roundish at the base, retuse at the top, with a wide leafy rim, having in each cell two oblong-ovate seeds, grooved on one side[i].

Native of the South of France and Italy.

Gardel's figure represents the plant larger, and the leaves more fleshy than it is even in gardens. Columna's figure is much better[k].

It varies with leaves almost flat, and little if at all ciliated[l].

6. Stem creeping. Leaves smooth, soft; those next the root quite entire and petioled, those on the stem smooth and entire. Flowers almost regular. Silicle subquadrangular. It resembles *Thlaspi saxatile*[m].

The roots creep far and wide and are much branched. Stems procumbent, a palm in length, leafy but not branched. Leaves succulent, glaucous, thinly serrate or entire. Corymbs dense. Calycine leaflets lanceolate. Petals scarcely, if at all, unequal, with a broad claw. Silicle long, ovate-lanceolate, and rendered almost square by a raised line. Seed single in each cell[n].

Stems naked, slender, creeping, branched. Branches creeping, naked, red at bottom, above leafy and ascending. Lower leaves like those of wild Thyme, smooth, thickish, soft, pale green, quite entire or with a tooth or two at top. Flowers in racemes, on spreading peduncles. Calyx reddish. Petals purple, with the border entire, blunt, oval. Silicle three lines long, somewhat oblique, oblong. Seed smooth, compressed, subovate, blunt, rufous, lanuginous where it adheres to the partition[o].

Native of Switzerland, Carniola, South of France, Italy, Silesia.—Cultivated by Mr. Miller in 1748. It flowers from may to july[p].

This and all the preceding sorts are perennial; the following are annual, except perhaps the next which seems to be perennial.

7. Root long, round, slender, fungous, branched, creeping obliquely, reddish violet coloured on the outside. Stems several, scarcely half a span in height, all prostrate, with the flowering tops curved upwards; they are smooth, round, tinged with reddish violet, leafy. Leaves copious, scattered, fleshy, very smooth, deep green, with sometimes a glaucous hue, but less than in the preceding; the lower obovate-oblong, somewhat decurrent, toothed towards the top; the upper sessile, oblong, subovate, quite entire, without any auricles at the base. Each flower pedicelled, all together forming first a corymb, afterwards a raceme. Calycine leaflets ovate, naked, entire, somewhat tinged with red on the outside, half the length of the corolla. Petals obovate-oblong, entire, equal, lilac-coloured. The flowers have the same pleasant smell with those of the preceding, which it is strange no author has observed. Silicle naked, from an ovate base rising into a four-sided pyramid, as in the preceding species. Seeds two, rufous, in each cell.

Native of Carinthia, flowering at the beginning of may[q].

Professor Jacquin doubts whether the Iberis rotundifolia of Scopoli be the same with this or the rotundifolia. He is of opinion that it does not agree with either of them.

8. Root of common Purple Candy-tuft is annual, white, oblong, fusiform. Stem upright, leafy, half a foot or a span to a foot in height, subangular, green, smooth, branching. Leaves frequent, alternate, lanceolate, acuminate, smooth. Flowers in a hemispherical corymb on peduncles half an inch in length. Outer petals more than twice as large as the inner ones[r]. Silicle ovate-rounded, triangular-emarginate at the top, so as to be as it were two-eared, a little flatted, convex on one side, flat or slightly concave on the other: valves navicular, with the keel broad, leafy-compressed and as it were extenuated into a wing: partition narrow, contrary to the valves, and bipartile. Seeds solitary, ovate, flatted, a little beaked near the umbilicus, ferruginous-ruscescent[s].

Native of the South of Europe. Cultivated in 1596 by Gerarde[t].]

The usual colour of the flowers is a pale purple, but there is one variety with bright purple, and another with white flowers; the latter however is seldom seen in our gardens, the seeds of the *amara* being commonly substituted for it. It flowers in june and july, and may be continued in succession till autumn.

[Gerarde says, that Candy-tuft, which he calls Candia Mustard or Candia Thlaspi grows in Austria, in untoiled places, and by highway sides: in Crete or Candia, in Spain and Italy, and such like hot regions, whence he received seed, by the liberality of the right honourable the Lord Edward Zouche, at his return into England from those parts. Parkinson calls it Spanish or Candy Tufts.

9. Linneus says that the White Candy-tuft resembles the preceding very much, only it is smaller. It is however sufficiently distinct in several circumstances. Stem seven or eight inches high, pubescent, somewhat rugged, branched; branches diffused, alternate, the lower ones sometimes opposite, not rising all to the same height. Leaves alternate oblanceolate or linear-lanceolate, blunt, sessile, decurrent, bright green, thickish, smooth, the lower ones serrate, the rest toothletted especially in front, or with a tooth or two on each side. Flowers white, in a terminating spike-like raceme; or rather, in a corymb lengthening into a raceme as the inflorence advances. Calyx erect. The two outer petals double the length of the two inner ones[u]. Silicles rounder and a little smaller than in the preceding, in other respects resembling those. Seeds more eliptic, flatted like a lens, paler and surrounded with a very narrow rim of a deeper colour[x].

Native of Switzerland, Germany, Austria, South of France and England. In Oxfordshire about Henley, Nettlebed and Mungewell. In Berkshire about Wallingford, common. Not mentioned as wild in England by any of our old writers.

10. Root simple, white, twisted, having few fibres. Root-leaves lanceolate-linear, serrate, withering and falling as the stem advances; stem-leaves linear; quite entire, sessile, few, gradually shorter, sharpish. Stem herbaceous, straight, slender, branched at top, branches mostly bifid. Flowers in corymbs, the outer ones peduncled, with the two outer petals larger. Silicles very retuse[y].

According

According to Linneus it reſembles *Lepidium graminifolium* very much, but is however different. Root-leaves ſomewhat toothed, ſmooth. Siliclés ovate, two-toothed with a truncated tip, whereas in *L. graminifolium* they are ovate-acuminate. The adult plant frequently caſts all its leaves.

Gouan ſays, that the ſtem puts forth immediately from the root ſome rigid faſtigiate purpliſh branches; that the root-leaves are like thoſe of *Iberis amara*, oblong, blunt, petioled, fleſhy, with two or three teeth towards the top, very ſeldom entire, purpliſh. Stem-leaves looſely alternate, longer, narrower and quite entire. Flowers purple, firſt in corymbs, then in racemes. Siliclés ovate, as it were cut off, with diverging points on each ſide, and toothed margins.

Native of Spain, Portugal, and Provence.—Cultivated by Mr. Miller in 1759. It flowers in july, and is annual [a].]

11. This ſeldom grows ſo large as the purple Candy-tuft, and the flowers are much ſmaller, but have an agreeable odour.

[The flowers are in cloſe corymbs and of a ſnowy whiteneſs.—Native of the mountains near Geneva. Cultivated by Mr. Miller in 1759.

12. Native of Arabia and Cappadocia.

13. Stem ſcarcely a hand's breadth (or from two to four inches in height, numerous, decumbent when young, riſing as they advance, and finally upright, ſimple, round and ſmooth, naked or with one (two or three) ſeſſile leaves below the middle. Root-leaves ſpread on the ground in a circle, petioled, ſomewhat more than an inch in length, ſmooth, ſinuated and pinnatifid, obtuſe, the lobes in ſome oppoſite, in others alternate, the terminating one very large and rounded. Flowers in a terminating ſpike-like raceme, ſmall, white, and without ſcent; on peduncles half an inch long, and ſpreading wide. Calycine leaflets broad-lanceolate. Corolla larger than the calyx; the two outer petals larger, ſpreading, the two inner bent in. Silicle ſomewhat convex on one ſide, flat on the other, bordered with a projecting margin, and marked with a perpendicular line, which is the edge of the partition. Seeds generally two in each cavity.

The more luxuriant the plant, the more it is diſpoſed to produce leaves on the ſtem; in this ſtate the lower ones are divided into three or five ſegments, but the upper ones are undivided and lanceolate. The flowers, which are very minute, appear in may and june. The ſeed-veſſels, which are large in proportion to the plant ſucceed in july.

Native of moſt parts of Europe, in dry and barren ſoils. With us, near London ſparingly; as on Hounſlow heath, Putney and Barnes commons, near Hampton-court and Richmond. Blackheath by the road from Greenwich to Lewiſham. Ilford in Eſſex. Near Gamlingay in Cambridgeſhire, Bury and Bungay in Suffolk, Norwich. Penſham in Worceſterſhire. Hammerhill near Salop. Nottingham-park. Little Creaton in Northamptonſhire. Near Sheffield and Eaſingwold, Yorkſhire. Between Corby Caſtle and Carliſle. And in Scotland [b].

14. Stem about half a foot in height, commonly ſimple, but ſometimes with a branch or two. Leaves pinnatifid, ſinuated or merely toothed. Flowers in a corymb, clear white, ſeldom purple. Silicle cleft at the end [c]. Linneus remarks, that the calyx is red, but the petals white, and when in fruit the form of the corymb continues, as in I. umbellata, without lengthening out into a raceme or thyrſe, as it does in ſome of the ſpecies [d].

Native of the South of Europe. Cultivated in 1640. It flowers from june to auguſt [e].]

PROPAGATION AND CULTURE.

1. This plant is ſomewhat tender, therefore is generally preſerved in green-houſes in winter, where, being placed among other low plants toward the front of the houſe, it makes an agreeable variety, as it continues flowering all the winter. But although it is commonly ſo treated, yet in moderate winters this plant will live in the open air, if it be planted in a warm

[a] Hort. kew. [b] Villars. [c] Linn. mant. [d] Curtis, Woodw. Miſs. Withering. [e] Hort. kew.

ſituation and on a dry ſoil; and if, in very hard froſt, it be covered either with mats, reeds, ſtraw, or peas-haulm, it may be preſerved very well; and theſe plants which grow in the full ground, will thrive better, and produce a greater number of flowers, than thoſe which are kept in pots; but the ſoil in which theſe are planted, ſhould not be over rich, nor too wet, for in either of theſe they will grow too vigorous in ſummer, ſo will be in greater danger of ſuffering by the froſt in winter; but when they grow on a gravelly ſoil, or among lime rubbiſh, their ſhoots being ſhort, ſtrong, and not ſo replete with moiſture, will better reſiſt the cold.

This plant very rarely produces ſeeds in England, therefore is only propagated by cuttings, which, if planted during any of the ſummer months, and ſhaded from the ſun, and duly watered, will be rooted in two months, and may afterwards be either planted in pots, or into the borders where they are deſigned to ſtand.

The variety with ſtriped leaves not being ſo hardy as this, muſt be treated more tenderly in winter, and may be increaſed by cuttings in the ſame manner.

2. This rarely producing ſeeds in England, is increaſed by ſlips, which in ſummer eaſily take root. The plants may be treated in the ſame manner with the firſt ſort, and will thrive in the open air.

[4. This is eaſily raiſed from cuttings, and may be kept through the winter in a common hot-bed frame; and in mild winters will ſtand abroad, eſpecially if ſheltered among rock-work. Moiſture often proves fatal to it in the winter ſeaſon, as it does to many other confined plants in mild moiſt ſeaſons. In this caſe the ſuperfluous moiſture muſt be diſſipated by gentle heat [f].]

5, 6, 7. Are propagated by ſeeds, ſown on a ſhady border in autumn; when the plants are ſtrong enough to remove, tranſplant them into a ſhady border, where they are to remain, and they will require no other care but to keep them clean from weeds.

8, 9, 11. Theſe are ſown in ſmall patches in the borders of the flower-garden; and by ſowing them at three or four different times, there may be a ſucceſſion of them in flower till autumn. When they are grown up they ſhould be thinned, that they may put out ſide branches, flower ſtronger, and continue longer in beauty. Formerly the eighth was ſown for edgings, but theſe and all annuals are unfit for that purpoſe.

10. This may be increaſed by cuttings in the ſame manner as the firſt ſort. Some of the plants may be ſet on a warm border, in a dry ſoil; leaving two or three in pots, to be ſheltered under a frame in winter, in caſe of a ſevere froſt.

13. This diminutive plant is rarely admitted into gardens. The ſeeds may be ſown in autumn where the plants are deſigned to remain, and require no other care but to keep them clean from weeds.

ICE HOUSE, a building ſunk in the ground to preſerve Ice for the uſe of a family in the ſummer ſeaſon.

In the choice of a ſituation for an Ice-houſe, the principal regard ſhould be, that of a dry ſpot of ground, for wherever there is moiſture, the ice will melt; therefore in all ſtrong lands, which detain the wet, there cannot be too much care taken to make drains all round the building, to carry off all moiſture; for when this is lodged near the building, it will occaſion a damp there, which will always be prejudicial to the keeping of the ice.

The next conſideration muſt be, to have the place ſo elevated, that there may be deſcent enough to carry off whatever wet may happen near the building, or from the ice melting; alſo, that the place be as much expoſed to the ſun and air as poſſible, and not placed under the drip, or in the ſhade of trees, as hath been

[f] Curtis.

too often practiſed, under a falſe notion, that if it ſhould be expoſed to the ſun, the ice will melt away in ſummer, which never can be the caſe where there is ſufficient care taken to exclude the outward air (which muſt always be regarded in the building of theſe houſes) for the heat of the ſun can never penetrate through the double arches of the building, ſo as to add any warmth to the air; but when the building is entirely open to the ſun and wind, all damps and vapours will thereby be removed from about the building, which can never be kept too dry, or free from moiſt vapours. As to the figure of the building, that may be according to the fancy of the owner; but for the well into which the ice is to be put, a circular figure is the moſt convenient; the depth of the well, as alſo the diameter of it, muſt be proportioned to the quantity of ice wanted, but it is alway beſt to have enough; for when the houſe is well built, it will keep the ice for two or three years: and there will be this advantage in having it large enough to contain ice for two years conſumption, that if a mild winter ſhould happen, when there is not ice to be had, there will be a ſtock to ſupply the want.

If the quantity wanting is not great, a well of ſix feet diameter, and eight feet deep, will be large enough; but for a large conſumption, it ſhould not be leſs than nine or ten feet diameter, and as many deep: where the ſituation is either dry chalk, gravel, or ſand, the pit may be entirely below the ſurface of the ground; but in ſtrong loam, clay, or moiſt ground, it will be the beſt way to raiſe it ſo high above the ſurface, as that there may be no danger from the wet.

At the bottom of the well there ſhould be a ſpace left, about two feet deep, to receive any moiſture which may drain from the ice, and a ſmall underground drain ſhould be lain from this, to carry off the wet; over this ſpace of two feet ſhould be placed a ſtrong grate of wood, to let the moiſture fall down, which may at any time happen, from melting of the ice. The ſides of this well muſt be walled up with brick or ſtone, at leaſt two feet thick; but if it is yet thicker, it will be better, becauſe the thicker the walls are made, the leſs danger there will be of the well being affected by any external cauſe. When the well is brought within three feet of the ſurface, there muſt be another outer arch or wall begun, which muſt be carried up to the height of the top of the intended arch of the well; and if there is a ſecond arch turned over from this well, it will add to the goodneſs of the houſe; but this muſt be ſubmitted to the perſon who builds, if he will be at the expenſe; but if not, then the plate into which the roof is to be framed, muſt be laid on this outer wall, which ſhould be carried high enough above the inner arch, to admit of a door-way in, to get out the ice. If the building is to be covered with ſlates or tiles, there ſhould be a thickneſs of Reeds laid under, to keep out the ſun and external air; if theſe Reeds are laid two feet thick, and plaſtered over with lime and hair, there will be no danger of the heat getting through it.

The external wall need not be built circular, but of any other figue, either ſquare, hexangular, or octangular; and where this ſtands much in ſight may be ſo contrived as to make it a good object. I have ſeen an Ice-houſe built in ſuch a manner as to have a handſome alcove ſeat in the front, and behind this ſeat was contrived a paſſage to get out and put in the ice; and by having the entrance behind, to the north aſpect, a ſmall paſſage being next the ſeat, through which a perſon might enter to take out the ice, and a large door being contrived with a porch, wide enough for a ſmall cart to back in, to ſhoot down the ice upon the floor near the mouth of the well, where it may be well broken, before it is put down. The aperture of this mouth of the well need not be more than two feet and a half diameter, which will be large enough to put down the ice, and if it was greater, it would be inconvenient; there ſhould be a ſtone fitted to ſtop this aperture, which muſt be cloſed up as ſecure as poſſible, after the ice is put in, and all the vacant ſpace above and between this and the outer door, muſt be filled cloſe with Barley Straw, to exclude the air; ſo the door to enter for taking out the ice ſhould be on the oppoſite ſide, immediately behind the alcove ſeat, as was before-mentioned; and this door ſhould be no larger than is abſolutely neceſſary for the coming at the ice, and muſt be ſtrong and cloſe to exclude the air; and at five or ſix feet diſtance from this another door ſhould be contrived, which ſhould be cloſely ſhut before the inner door is opened, whenever the ice is taken out.

The building being finiſhed, ſhould have time to dry before the ice is put into it; for when the walls are green, the damp of them frequently melts the ice. At the bottom of the well, upon the wooden grate, ſhould be laid ſome ſmall faggots; and if upon theſe a layer of Reeds is placed ſmooth for the ice to lie upon, it will be better than Straw, which is commonly uſed; and in the choice of the ice, the thinner it is, the better it may be broken to powder; for the ſmaller it is broken, the better it will unite when put into the well: in putting of it in, there muſt be care taken to ram it cloſe, as alſo, by laying Straw, to allow a vacancy all round next the wall, of about two inches; this is to give paſſage to any moiſture, which may be occaſioned by the melting of ſome of the ice on the top, which, if pent up, will melt the ice downward; when the ice is put into the well, if there is a little ſalt-petre mixed at every ten inches or a foot thickneſs, it will cauſe the ice to join more cloſely into a ſolid maſs.

[The ice being all incorporated into one ſolid body, there muſt be a crow or other iron inſtrument always in readineſs to break it up; taking out no more at a time than is wanted.

Mr. Miller propoſes to make uſe of the Ice-Houſe as an ornamental building; that however is ſeldom done: and it is generally placed in a ſequeſtered ſpot, on the ſide of a hill or ſloping ground, the baſe of which is lower than the bottom of the well; the outſide being well banked up with earth, the better to keep out all air and heat, and the enbankment being neatly covered with turf.

For the dimenſions and other particulars of the building ſee the plate.

Poſoqueria longiflora. *Aubl. guian.* 134. *t.* 51.
Leaves oblong waving acuminate, peduncles terminating, ſix-flowered or thereabouts.

DESCRIPTIONS, *&c.*

1. This is a very branching tree, the branches long, round, very ſmooth, climbing. Leaves oppoſite, petioled, a ſpan long, quite entire, veined, very ſmooth, flat. Flowers in ſmall panicles; peduncles bearing from three to five flowers; pedicels ſhort, round, rigid. Flowers very long, nodding, white, having the ſmell of Jaſmine. Fruit ovate, with a very ſmooth dry rind, narrowed at the neck, the ſize of a Bonchretien Pear[a].

Loureiro, who ſaw it in a growing ſtate, deſcribes it as a large ſhrub, with a trunk like a tree, and many, very long, climbing, unarmed branches. Leaves large. The tube of the corolla reclining. The fruit a large roundiſh berry, attenuated at the neck, juiceleſs; the rind very ſmooth, woody, whitiſh, like the bottle Gourd when ripe. Seeds three-cornered ovate, browniſh aſh-colour, ſmooth, of a horny ſubſtance, and a very bitter taſte.

Gærtner ſays, that the ſeeds are rather large, and different in ſhape; ſome, which ſeem to be central, oblong, very bluntly angular; others, towards the outſide, ſhorter, quadrilateral, one ſide larger and a little convex, the three others flat, triangular, converging into a very blunt pyramid. All are of a duſky brown or ſmoaky colour, the ſurface rugged with very minute wrinkles, and the umbilicus perforated on the edge or at the baſe.

Juſſieu joins this plant with Strychnos, nor is the fruit in the two genera very different, except that the cotyledons are petioled, which is peculiar to Ignatia and Gyrocarpus[b].

Native of the Eaſt Indies and the Philippine iſlands, whence it has been tranſported to Cochinchina and other countries for cultivation.

The ſeeds, which are known by the name of St. Ignatius's beans, are much uſed in the Eaſt Indies, and are reputed to be tonic, diaphoretic, emmenagogue, and anthelmintic. They are uſed in the pituitary apoplexy, colic, cardialgia, intermittent fevers, ſuppreſſion of the menſes, and bites of venomous animals. They may be taken internally from ſix to twelve grains, in powder, either in wine or water, generally with good effect, ſometimes without any, but never with any danger. Too large a doſe will bring on vertigo and convulſions, but they are eaſily cured by lemonade drank largely.

What the younger Linneus affirms, namely that the ſeeds are equally poiſonous to animals with nux vomica, is a miſtake; for a whole nut weighing a dram, has been given to oxen, buffaloes, horſes and ſwine, without any damage. Nor is it true that theſe ſeeds are never ſpoiled by keeping, or by worms, for they are frequently found with holes eaten in them, eſpecially in the Eaſt Indies and in moiſt places[c].

2. This is a branching ſhrub five or ſix feet high, with a ſmooth green bark, and a white hard wood. It begins to put forth branches at two feet from the ground: they are knotty, twiſted and ſubdivided into oppoſite twigs. At each joint are two leaves oppoſite, ſmooth, entire, thin, oblong, waving on the edge, ending in a long point: petiole an inch long, convex below, channelled above: the largeſt leaves are ſeven inches long, and two and a half wide: between them on each ſide is a broad, ſtiff, ſharp ſtipule. Flowers terminating, about ſix in number, on a common peduncle, having two ſcales at its baſe, beſides three or four ſmaller ones ſcattered on each pedicel. Corolla white, with a tube a foot in length.

Native of Guiana on the banks of large rivers: flowering in november, and fruiting in january. The Caribbee name is Aymara-Poſoqueri[d].]

DESCRIPTIONS, *&c.*

This genus conſiſts of ſmall trees or ſhrubs; with alternate leaves, evergreen, toothed and thorny; and axillary many-flowered pedunclesª.]

1. The Common Holly riſes from twenty to thirty feet, and ſometimes more. [Bradley mentions a tree ſixty feet in height]; but its ordinary height is not above twenty-five feet. The trunk is covered with a grayiſh ſmooth bark, and thoſe trees which are not lopped or browzed by cattle, are commonly furniſhed with branches the greateſt part of their length, and form a ſort of cone. Leaves petioled, about three inches long and one and a half broad, of a lucid green on their upper ſurface, but pale on their under, having a ſtrong midrib; the edges are indented and waved, with ſharp thorns terminating each of the points, ſome raiſed upwards, others bent downwards, and being very ſtiff, the leaves are troubleſome to handle; [theſe thorns are fixed into a ſtrong woody border which ſurrounds the leaf. When this tree grows naturally, it has flat, entire leaves, without thorns, only ending in a ſharp point, mixed with the others, eſpecially as it advances in age.] Flowers in cluſters from the baſe of the petioles [from a ſort of ſcale upon the branch, *With.*] on very ſhort peduncles, each ſuſtaining five, ſix or more flowers, [generally three together, *W.*] appearing in may. The corolla of a dirty white. They are ſucceeded by roundiſh berries, [crowned with the calyx, which turns black, *W.*] turning to a beautiful ſcarlet about michaelmas, and containing the greater part of the winter. [Seeds three or four, *W.*

The difference of ſexes in the flowers of the Holly was firſt obſerved by my father. In his garden at Streatham in Surry he had many of theſe trees, which before he had poſſeſſion of the place were ſhorn into round heads: he emancipated them from their ſlavery, pruned them, and trained up leading ſhoots; ſeeming glad to be releaſed from their ſhackles, they quickly ſhot up into goodly trees, and ſoon rewarded him with this diſcovery concerning the nature of their flowers, which he communicated to the Royal Society, and is printed in their tranſactions. I perfectly recolleſt having carefully attended to the flowering of theſe trees during ſeveral ſeaſons, and having uniformly obſerved hermaphrodite flowers on ſome and male flowers on others in the former the anthers were different from thoſe in the male flowers, and appeared to be effete, and there never was a ſingle male flower mixed with the hermaphrodite, or a hermaphrodite with the males, or any flower except the two here deſcribed. Others however have remarked a different and more varied diſpoſition of the ſexes.]

Mr. Miller ſays, in ſome plants I have obſerved the flowers were wholly male and produced no berries, in other female and hermaphrodite flowers, but upon ſome large old trees growing in Windſor foreſt, I have obſerved all three upon the ſame trees. [The late Sir William Watſon alſo made an obſervation of the ſame ſort. Gerard remarked hermaphrodite flowers with five petals on one tree, and male flowers with a four-parted petal and an abortive germ on another tree. Certainly in the trees which I obſerved all the petals were four-parted; and Dr. Withering ſays, that he found the Holly in flower ſo late as the ſecond week in june, and then *all the flowers* had four ſtamens and four piſtils. Haller alſo remarks, that in all the flowers which he had an opportunity of examining the corolla had the ſame ſtructure. Mr. Hudſon however deſcribes a five-toothed calyx and five-parted corolla in the hermaphrodite with five ſtamens, four ſtigmas, and a four-ſeeded berry; in the male, a four-toothed calyx, a four-parted corolla and four ſtamens. But whether this be from his own obſervation, or founded only on Gerard's, we are at a loſs to know. He has removed the Holly from the claſs where Linneus and others have placed it into the claſs Polygamia Dioecia, where it ſhould properly be found according to the obſervations given above. But it is very well remarked by Dr. Stokes, that before it be removed to another claſs, it is proper to ſhow, that the majority of the other ſpecies are liable to ſimilar ſexual variations. In the mean time the claſs Polygamia itſelf ſeems to be vaniſhing from the ſyſtem.

The common Holly grows wild in many parts of Europe, in North America, Japan, Cochinchina, &c.] It is found in woods and foreſts in many parts of England. [It grows ſo ſpontaneouſly, ſays Mr. Evelyn, in this part of Surry, that the large vale near my own dwelling was anciently called *Holmeſdale*: in Dungeneſs in Kent, it grows naturally among the pebbles upon the very beach. Dr. Withering ſays, that on the north ſide of the Wrekin in Shropſhire the trees grow to a large ſize. The Holly is very common in the chiltern diviſion of Buckinghamſhire, and where permitted has a conſiderable growth. Mr. Bradley tells us, that he has ſeen it above ſixty feet high in the Holly walk near Frenſham in Surry.

The Holly is called alſo in Engliſh Hulver and Holme. It is known by the name of Hulver in Norfolk. In German it has a great variety of appellations, *Stechpalme, Stecheiche, Stechbaum, Steechlaub, Hulſe, Hulſenbaum, Hulſenſtrauch, Hulſt, Hulch, Holſt, Hubze, Hullgebobz, Myrtendorn, Chriſtdorn, Mauſedorn, Zwiefeldorn, Kleeſebuſch, Stechapfel, Stechwinde, Walddiſtel.* In Daniſh, *Stikpalme, Maretorn, Chriſttorn, Skoutiſdel.* In Swediſh, *Jernek, Chriſtorn.* In French, *le Houx, le grand Houſſon, L'Agrou, grand Pardon, Bois Franc.* In Italian, *Agrifolia, Alloro ſpinoſo.* In Spaniſh, *Acebo, Agrifolio.* In Portugueze, *Azevinho, Agrifolio, Acrifolio, Aquifolio.* In Ruſſian, *Watoſoheld, Oſtrokof, Padub.*

The Holly makes an impenetrable fence, and bears cropping well, nor is its verdure, or the beauty of its ſcarlet berries, ever obſerved to ſuffer from the ſevereſt of our winters[b]. It would claim the preference for this purpoſe even to the Hawthorn, were it not for the ſlowneſs of its growth whilſt young, and the difficulty of tranſplanting it when grown to a moderate ſize. But when it once takes well, the hedge may be rendered ſo cloſe and thick, as to keep out all ſorts of animals[c]. Mr. Evelyn's impregnable Holly hedge, four hundred feet in length, nine feet high, and five

ª Juſſieu.

[b] Witherıng. [c] Hunter's Evelyn.

in.

in diameter, has been much celebrated by himself, Ray and others.

It does beſt in cold, ſtony lands, according to Dr Hunter; it certainly proſpers on gravel over chalk. It refuſes not, ſays Mr. Boutcher, the pooreſt hot ſandy gravelly and rocky ground, nor the coldeſt clay. On the latter, however, I have never ſeen it advance but with moſt diſcouraging ſlowneſs. Mr. Marſhall relates, that in the Wolds of Yorkſhire, he has ſeen the Holly raiſed (by the practice of a man who has paid great attention to the buſineſs of hedge-planting) with an unuſual degree of rapidity and certainty[a]. This man's ſecret would be of ineſtimable value to the public.]

Mr. Miller directs that a Holly hedge ſhould never be clipped with ſheers, becauſe when the leaves are cut through the middle, they are rendered unſightly, and ſhould therefore be cut with a knife cloſe to a leaf; and although by this method, it is not ſhorn ſo even, yet it will have a much better appearance. [This may be an attention due to a garden hedge, but it is obvious that on a large ſcale it is impracticable, and except for mere ornament it is unneceſſary. Mr. Boutcher adds, that if a hedge be clipped at all, it ſhould not be done later in the ſeaſon than july.

The common Holly being a very beautiful tree in winter, deſerves a place in all plantations of evergreen trees and ſhrubs, where its ſhining leaves and ſcarlet berries make a fine variety; and if a few of the beſt variegated ſorts are properly intermixed, they will enliven the ſcene.

The wood of this tree, ſays Mr. Evelyn, is the whiteſt of all hard woods, and uſed by the inlayer, eſpecially under thin plates of ivory. The mill-wright, turner and engraver preſer it to any other. It makes the beſt handles and ſtocks for tools, flails, the beſt riding-rods and carter's whips; bowls, chivers, and pins for blocks; alſo it excels for door-bars and bolts.] Mr. Miller adds, that it is made into hones for ſetting razors; that the wood taking a fine poliſh, is very proper for ſeveral kinds of furniture; and that he had ſeen the floor of a room laid in compartments with this and mahogany, which had a very pretty effect. [It is much uſed, with Box, Yew, White-thorn, &c. in the ſmall trinkets and other works, carried on in and about Tunbridge, and commonly called Tunbridge ware. The wood, ſays Dr. Withering, is uſed in fineering, and is ſometimes ſtained black to imitate Ebony.

Sheep and deer are fed during winter with the croppings. Birds eat the berries. The bark fermented, and afterwards waſhed from the woody fibres, makes the common Birdlime.

Varieties.

Forty or fifty varieties, depending on the variegations of the leaves or thorns, and the colour of the berries, all derived from this one ſpecies,] are raiſed by the nurſery-gardeners for ſale, and formerly were in very great eſteem, but are now leſs regarded, ſince the old taſte of filling gardens with ſhorn Ever-greens has been laid aſide; a few, however, of the moſt lively varieties ſhould be admitted in plantations, and will have a good effect in the winter ſeaſon, if they are properly diſpoſed.

[Of the varieties enumerated above, the Hedge-hog Holly is the moſt remarkable. Mr. Miller will have it to be a diſtinct ſpecies; and ſays,] that the leaves are not ſo long as thoſe of the common Holly, and have the edges armed with ſtronger thorns, ſtanding cloſer together; the upper ſurface ſet very cloſe, with ſhort prickles. It grows naturally in Canada, and keeping its difference when raiſed from the berries, Mr. Miller makes no doubt of its being a diſtinct ſpecies.

There are two varieties of this with variegated leaves, one yellow, and the other white.

[The Hedge-hog Holly was cultivated in the garden of Compton, Biſhop of London, at Fulham, by that ingenious and ſkilful gardener Mr. George London, who is ſuppoſed to have introduced it firſt from France[a].

The variety with yellow berries has been found wild in England by Wardour Caſtle, and Mr. Dale was ſhown it at Wiſton near Buers in Suffolk[b].

Mr. Miller mentions the following varieties as the moſt beautiful. Painted Lady. Britiſh. Bradley's beſt. Phyllis or Cream. Milkmaid. Prichet's beſt. Cheyne's. Glory of the Weſt. Brolerick's. Partridge's. Herefordſhire White. Blind's Cream. Longſtaff's. Eales's. Gold edged, and Silver-edged Hedge-hog Holly.

[To theſe may be added, from later catalogues Box-leaved green. Chohole. Chimney-ſweeper. Glory of the Eaſt. Wiſe's. Gray's. Common blotched. Yellow blotched Hedge-hog. Blotched yellow-berried. Maſon's copper-colotired. Sir Thomas Frankland's Britain. Whitmill's. Bradley's long-leaved. Bradley's yellow. Bridgman's. Wells's. Glaſs's. Bagſhot. Brownrig's. Lanton. Aſlet's. The Union. Fuller's Cream. Capel's Mottled. White-berried.—But enough of mere arbitrary names, without diſtinction.

2. Native of Carolina. Cultivated in 1744, by Archibald, Duke of Argyle. It flowers in may and june.

3. Native of Madeira. Introduced in 1760, by Mr. James Gordon. It flowers in april and may.

4. Native of Carolina and Virginia. Cultivated before 1760, by Archibald, Duke of Argyle. It flowers in july[c]. Of theſe we have no deſcriptions.]

5. The Dahoon Holly riſes with an upright branching ſtem to the height of eighteen or twenty feet; the bark of the old ſtems is of a brown colour, but that of the younger ſtems or branches is green and ſmooth. Leaves more than four inches long, and one and a quarter broad in the broadeſt part, of a light green and thick conſiſtence; the upper part is ſerrate, each ſerrature ending in a ſmall ſharp ſpine; they ſtand alternately on every ſide of the branches, on very ſhort foot-ſtalks. The flowers come out in thick cluſters from the ſide of the ſtalks; they are white, and ſhaped like thoſe of the Common Holly, but ſmaller. Both the female and hermaphrodite flowers are ſucceeded by ſmall roundiſh berries, making a fine appearance in winter; but they have not as yet produced fruit in England.

Native of Florida and Carolina, whence the ſeeds were ſent [about the year 1726] by Mr. Mark Cateſby, who found the trees growing on a ſwamp at a diſtance from Charles-town.

[There are two varieties of the Dahoon Holly, as mentioned above, one with broader leaves, and the other with narrower leaves, with ſcarcely any ſerratures.]

6. South-ſea Tree or Evergreen Caſſine riſes to the height of ten or twelve feet, ſending out branches from the ground upwards, which form themſelves into a ſort of pyramid. Leaves about the ſize, ſhape, texture and colour of the ſmall-leaved Alaternus, but ſomewhat ſhorter, and a little broader at the baſe. The flowers are produced in cloſe whorls at the joints of the branches, near the foot-ſtalks of the leaves: they are white, and are ſucceeded by red berries, which continue upon the plants moſt part of the winter, and being of a bright red colour, make a fine appearance, intermixed with the green leaves. From their continuing ſo long untouched by birds, in a country where theſe animals are ſo numerous, we may conclude that they have ſome venomous quality in them.

[Native of Weſt Florida[d].] Mr. Miller ſays, Carolina, and ſome of the warm parts of Virginia, chiefly near the ſea. [It was cultivated here in 1700[e];] and preſerved in ſeveral curious gardens near London, till the ſevere winter 1739, when moſt of them were deſtroyed. But ſince that many young plants have been raiſed from ſeeds, and have reſiſted the cold of our winters without covering; though they often ſuffer in very cold ſeaſons, where they are not very well ſheltered.

[a] Rur. econ. of Yorkſh. 2. 203.

[a] Raii hiſt. [b] Ibid. [c] Raii ſyn. and Evelyn. [d] Hort. kew. [e] Ibid. from Plukenet, mant. 40.

The leaves of this are not ſo bitter as thoſe of the Caſſine or Caſſioberry buſh, eſpecially when green, and therefore are preferred for making an infuſion in the manner of Tea; which is accounted by the Indians very wholeſome, and is almoſt the only phyſic they uſe in ſome parts. At a certain time of the year they come down in droves, from a diſtance of ſome hundred miles, to the coaſt, for the leaves of this tree, which is not known to grow at any conſiderable diſtance from the ſea. They make a fire on the ground, and putting a great kettle of water on it, they throw in a large quantity of theſe leaves, and ſetting themſelves round the fire, from a bowl that holds about a pint, they begin drinking large draughts, which in a very ſhort time occaſion them to vomit eaſily and freely: thus they continue drinking and vomiting for the ſpace of two or three days, until they have ſufficiently cleanſed themſelves: and then every one taking a bundle of the tree to carry away with him, they all retire to their habitations.

This plant is generally ſuppoſed to be the ſame as that which grows in Paraguay, where the Jeſuits make a great revenue from the leaves, and of which an account is given by Mont. Frezier.

[7. Native of the Eaſt Indies.

8. Native of South America[k].

9. Stem ſhrubby, upright. Branches and branchlets alternate, angular, ſpreading, brown. Leaves ovate, quite entire, with the margin a little bent back, pale underneath, an inch long. Petioles three-ſided, ſhort. Flowers in a ſeſſile umbel. Peduncles in fours or thereabouts, angular, erect, very ſhort.

10. Stem ſhrubby. Branches ſubumbelled, ſomewhat knobbed. Leaves towards the end of the branchlets, ſcattered, frequent, rounded-ovate, ſmooth, paler underneath, an inch and half long, on petioles ſhorter by half than the leaves themſelves.

11. Stem ſhrubby, upright. Branches and branchlets, roundiſh, ſomewhat knobbed and ſpreading. Leaves ſcattered, blunt, with a reflex margin, pale underneath, on very ſhort petioles. Peduncles ſimple, bifid and trifid, drooping; the pedicels very ſhort.

12. Stem ſhrubby. Branches round, flexuoſe, aſh-coloured, ſmooth; branchlets alternate, ſomewhat ſtriated and ſpreading. Leaves on very ſhort petioles, blunt, crenate, rolled back at the edge, green above, with a longitudinal groove, pale underneath, with the midrib raiſed, ever-green. Flowers peduncled, generally two together, very ſeldom ſolitary.

13. Stem ſhrubby, upright, branching very much; branches round, even, ſmooth, aſh-coloured; branchlets filiform, ſpreading a little. Leaves acuminate, pale underneath, thin, ſpreading, half an inch long, on petioles ſcarcely a line in length. Flowers on filiform drooping peduncles, half a line long. Corolla four-petalled. It flowers in june.

14. Stem ſhrubby, ſmooth, low. Leaves ovate, acuminate, tooth-ſpiny, ſmooth, an inch and half long. Raceme a finger's length. Bractes oppoſite, or in threes or fours, ovate, acute, ſmooth, ſpreading. Peduncles from the axils of the bractes, ſolitary, one-flowered, capillary, a little longer than the bractes. Calyx ſhorter than the corolla, appearing rather to be four-leaved. Corolla ſubrotate: petals obovate, entire, white. Germ ſuperior, oblong. It flowers in april.

15. Stem arboreſcent. Branches rigid, angular, brown. Leaves blunt-iſh, with a reflex margin, ſhining above, pale underneath, ſpreading, two inches broad and three inches long. Petioles ſlightly three-cornered, channelled. Flowers ſuperaxillary, many together from the gems, on ſhort peduncles[l].

16. Native of the Cape of Good Hope[m].

PROPAGATION AND CULTURE.

1. The Holly is propagated by ſeeds, which never come up the firſt year, but lie in the ground as the Haws do; therefore the berries ſhould be buried in the ground in a large pot or tub one year, and then taken up and ſown in the autumn upon a bed expoſed only to the morning ſun; the following ſpring the plants will appear, which muſt be kept clean from weeds; and if the ſpring ſhould prove dry, it will be of great ſervice to the plants if they are watered once a week: but they muſt not have it oftener, nor in too great quantity, for too much moiſture is very injurious to theſe plants when young.

In this ſeed-bed the plants may remain two years, and then ſhould be tranſplanted in the autumn, into beds at about ſix inches diſtance each way, where they may ſtand two years longer, during which time they muſt be kept conſtantly clean from weeds; and if the plants have thriven well, they will be ſtrong enough to tranſplant where they are deſigned to remain; for when they are tranſplanted at that age, there will be leſs danger of their failing, and they will grow to a larger ſize than thoſe which are removed when they are much larger; but if the ground is not ready to receive them at that time, they ſhould be tranſplanted into a nurſery in rows at two feet diſtance, and one foot aſunder in the rows, in which place the plants may remain two years longer; and if they are deſigned to be grafted or budded with any of the variegated kinds, that ſhould be performed after the plants have grown one year in this nurſery; but the plants ſo budded or grafted ſhould continue two years after in the nurſery, that they may make good ſhoots before they are removed; though the plain ones ſhould not ſtand longer than two years in the nurſery, becauſe when they are older, they do not tranſplant ſo well. The beſt time for removing Hollies is in the autumn, eſpecially in dry land; but where the ſoil is cold or moiſt, they may be tranſplanted with great ſafety in the ſpring.

[Hedges of Holly are raiſed, either by ſowing the berries where they are deſigned to remain, or by plants of three or four years growth; but the latter method is the moſt uſual: early in the autumn is the beſt time for planting them, eſpecially in dry grounds; or if it be deferred to the end of march, mulch muſt be laid to their roots, to keep them from drying, and they muſt be watered once a week, if the ſeaſon ſhould prove dry[n].

Mr. Evelyn affirms, that he has raiſed hedges four feet high in four years, from ſeedlings taken out of the woods. I could never meet with any ſucceſs in this way, and am confident that plants from the nurſeries are far more likely to enſure ſucceſs.

Mr. Bradley obſerves, that the Holly being tap-rooted, does not love tranſplanting, unleſs the roots have been often pruned in the nurſery. He ſays, the earth in which it is to be planted cannot well be too barren; and that ſeptember is the beſt month for tranſplanting it.

For ſowing, Mr. Boutcher directs, that the berries ſhould hang on the trees till december, or if they could be defended from birds, till february or march. As ſoon as they are gathered throw them into a tub with water, and rub them between your hands, till the ſeeds are diveſted of their thick glutinous covering. Pour off the water, with the light ſeeds that ſwim, the mucilage, &c.; and ſpread the ſeeds on a cloth in a dry airy place, rubbing them often, and giving them a freſh cloth daily till the ſeeds are quite dry. If this be done in autumn or winter, mix them with ſand, and keep them dry till ſpring; but if they have been gathered in ſpring, let them be immediately ſown. This may be done any time in march or april, when the weather is ſeaſonable, in beds of looſe light mould, three feet and a half broad, with alleys of eighteen inches between. Let the berries be ſown regularly, and not too cloſe, covering them with fine mould three quarters of an inch deep. The following year, in the beginning of april, draw out ſuch a number of plants as to leave the reſt thin enough to receive all the influence of the ſun. Plant thoſe that are drawn in a ſhady border, in rows eighteen inches aſunder, and five or ſix inches diſtant in the rows. In this ſituation they may remain three years.

Profeſſor Bradly has given a method of forwarding the germination of theſe and other hard ſeeds, for which

[k] Linn. ſpec. [l] Thunb. jap. [m] Thunb. cap. [n] Hunter's Evelyn.

he

he pretends to have been obliged to the incomparable Sir Isaac Newton.

Having obſerved that berries of this kind which have been eaten by fowls, and paſs through their bodies, begin to vegetate ſoon afterwards, we have no more to do than to contrive a mixture, which ſhall have in it a heat and moiſture reſembling that in the bodies of birds, and to lay the ſeeds in it for a few days before we ſow them. For this purpoſe provide a buſhel of bran, with which mix your ſeeds, and then wet the whole very well with rain or pond-water, and let the preparation remain ten days without any diſturbance in a veſſel of wood or ſtone. In about three days the mixture will begin to ferment, and ſo continue thirty or forty days, if it be ſprinkled from time to time with warm water, as it begins to dry. The heat of this moiſtened bran will put the berries into a ſtate of vegetation fit for ſowing in about a week's time after the fermentation has commenced [a].

Mr. Evelyn affirms, that the varieties with white berries, and gold and ſilver leaves, may be raiſed from ſeeds ſown and planted in a gravelly ſoil, mixed with ſtore of chalk, and preſſed hard down.]

Mr. Miller alſo ſays, that he has raiſed the Hedge-hog Holly from the berries, and always found the plants to continue the ſame.

They are, however, all uſually propagated in the nurſeries by budding or grafting upon the common Holly.

[The Stocks will be fit to be grafted or budded on at four or five years growth. The grafting muſt be done in march, and the budding in july [b].]

5. The Dahoon Holly, being tender whilſt young, requires protection in the winter till the plants are grown ſtrong and woody, when they may be ſet in the full ground, in a warm ſituation, where they will endure the cold of our ordinary winters pretty well; but in ſevere froſt they ſhould be protected, otherwiſe the cold will deſtroy them.

It is propagated from ſeeds, in the ſame manner as the common ſort. The ſeeds will lie as long in the ground, they ſhould therefore be buried in ſand a year, [unleſs they are forwarded in the ways above directed,] and then taken up and ſown in pots filled with light earth, and placed under a frame in winter; in the ſpring the pots ſhould be plunged into a hot-bed, which will bring up the plants; theſe muſt be preſerved in the pots whilſt young, and ſheltered in winter under a common frame till they have obtained ſtrength, when in the ſpring they may be turned out of the pots, and planted in the full ground, in a warm ſituation.

Theſe directions may ſerve for the ſecond and fourth ſorts. The third requires the protection of a green-houſe. The other ſorts have not been introduced.

6. This alſo is propagated from ſeeds, ſown in pots filled with light ſandy earth, and plunged into a gentle hot-bed, obſerving to water them frequently, until the plants appear, which is ſometimes in five or ſix weeks time; but at other times they will remain in the ground until the ſecond year; therefore if the plants ſhould not come up in two months, remove the pots into a ſhady ſituation, where they may remain till october, being careful to keep them clean from weeds, and now and then in dry weather giving them a little water; then remove the pots into ſhelter during the winter; and in march put them upon a freſh hot-bed, to forward the ſeeds for vegetation.

When the plants are come up, expoſe them to the open air by degrees, to inure them to the climate; yet they ſhould not be expoſed to the open ſun at firſt, but have the morning ſun only; placing them for ſome time where they may be ſheltered from cold winds. They ſhould be kept in pots four or five years; being ſlow of growth, and not having ſtrength enough to reſiſt the cold when young.

DESCRIPTIONS, *&c.*

1. Stem naked, obſcurely angular. Leaves petioled, lanceolate-ovate. Spikes ſeveral, ſmall, villoſe, white, glomerate, from all the axils of the leaves and branches. It is an annual plant, and a native of the Eaſt Indies.[a]

2. Stem uſually proſtrate, and very much branched. Spikes cluſtered, ſeſſile, alternate, looſe, tomentoſe, Calyx green, pubeſcent. Anthers yellow. Piſtil purple. Leaves red on both ſides, but the upper ſide darker. This is perennial, and native of the Eaſt Indies[b].

3. This is ſufficiently diſtinguiſhed from the other ſpecies by its woody arboreous ſtem, and its terminating dichotomous panicles. Found on the iſland of Teneriffe by Maſſon[c].

4. Stem rigid, ſomewhat hairy, branched only at the baſe. Leaves petioled, quite entire, ſharpiſh, naked, pubeſcent underneath. Peduncles lateral, very ſhort, in three or four ſeſſile ſpikes, unequal to the leaflet. Stamens connected at the baſe by means of a five-toothed crown. Seed kidney-form[d].

Loureiro adds, that the ſtem is round, and the branches diffuſed; the leaves lanceolate-ovate, ſubſeſſile, *oppoſite*; the ſpikes cloſe, oblong, axillary; the calyx compreſſed and red; the capſule compreſſed; and the ſeed round-compreſſed, hooked.

Native of the Eaſt Indies and Cochinchina, both in fields and gardens.—Cultivated in 1691, in the royal garden at Hampton Court. It is a biennial plant, and flowers moſt part of the year. It varies in ſize. The ſmaller one is deſcribed above. The great woolly Illecebrum has ſolitary, not aggregate ſpikes[e]. Retzius mentions a remarkable variety with round leaves, in Malabar.

5. Leaves like thoſe of Mercurialis tomentoſa, obovate-lanceolate, white-tomentoſe underneath, aſh-coloured above. Spikes approximating. Calyx hyaline, with a green keel. Germ globular. Stigmas two, red[f].

Native of the Eaſt Indies, and cultivated in 1768 by Mr. Miller[g], whoſe deſcription has been already given under *Celoſia lanata*, which is the ſame plant with this, and is repeated here, becauſe this ſeems to be its proper place. It is not eaſy, without more accurate notice than we ſometimes poſſeſs, to aſcertain whether a plant belongs to this genus, or Celoſia, Herniaria, Achyranthes, or Gomphrena.

6. This little plant, which by our Engliſh writers is called Whorled Knot-graſs, is only about three inches high. Stems filiform, branched, hirſute, with ſilvery hairs. Leaves oppoſite, oval, keeled, fleſhy, ſmooth, quite entire, ſeſſile, nearly of the ſame form and ſize with thoſe of Serpyllum or wild Thyme. Flowers ſmall, ſitting in the axils of the leaves, white, ſhining, cartilaginous. Upper whorls crowded near together, by no means ſo far aſunder as repreſented in Flora Danica[h]. Native of many parts of Europe, in wet

paſtures.

paſtures. Ray obſerved it both in Flanders and Germany. He ſays it loves boggy places with Nummularia rubra and Portulaca aquatica. It was not known in his time to grow wild in England, except in the weſtern part of Cornwall, about Penſance and elſewhere; but it has ſince been found not uncommonly in Devonſhire. It flowers in july and auguſt.]

7. This has woody ſtems about a foot high, with ſmall leaves like thoſe of Knot-graſs. The flowers come out ſingly on the ſide of the ſtems, and make little appearance.

[Native of the South of Europe. Cultivated in 1739 by Mr. Miller. It flowers from may to auguſt [1].

8. This has the appearance of Sedum and Polygonum (Knot-graſs). Stem filiform, brachiate. Leaves in fours or thereabouts, linear, thickiſh. Flowers in ſpikes directed one way, the ſpikes compoſed of cymes both lateral and terminating. Calyxes coloured, vaulted at the tip, and awned [2].

It is more particularly deſcribed by Gerard. Root annual, ſimple, herbaceous, whitiſh. Stems procumbent, from two inches to half a palm in length, jointed, knotty, the joints more frequent at the baſe and top, round with very ſhort villoſe hairs. Leaves obovate, ſeſſile; the lower ones in pairs oppoſite, broader and more obtuſe, naked; the reſt in fours or more, coming out together from the axils of two oppoſite leaves, narrower, ſharper and ſubciliate. Bractes lanceolate, acute, membranaceous, diaphanous, faſtened to the outer baſe of the leaves, and much ſhorter than they are. Flowers numerous, cluſtered, ſeſſile, lateral, from the axils of the leaves. Calyx bell-ſhaped, herbaceous, coriaceous, ſwelling at the baſe, five-cleft; the ſegments continued to the very baſe, linear-ſubulate, ending in rigid, recurved briſtles, at the bottom of the recurved part having an appendicle to each cloſing the mouth of the calyx. Filaments faſtened to the baſe of the calyx, very ſhort and ſlender. Germ roundiſh: ſtyle ſimple, very ſhort. Seed roundiſh, compreſſed, with a diaphanous membrane drawn over it. Calyx permanent.

Native of the South of France, the iſle of Elbe and Portugal.

9. This is a biennial plant, native of the Canary iſlands, where it was found by Mr. Francis Maſſon. Introduced in 1780. It flowers in june and july [3].]

10. This has trailing ſtalks near two feet long, with leaves like thoſe of the ſeventh ſort; the heads of flowers come out from the joints of the ſtalk, having neat ſilvery bractes ſurrounding them, which make a pretty appearance. The flowers appear in june, and there is generally a ſucceſſion of them for at leaſt two months, and when the autumn proves warm, the ſeeds will ripen at the beginning of october.

[It differs from the next ſpecies in being perennial, in having longer creeping ſtems, and ſmaller heads of flowers [4].

Native of the South of Europe. Cultivated here in 1640, as appears from Parkinſon.

11. Native of the Canary iſlands, where it was found by Maſſon. Introduced in 1779. It flowers in july and auguſt [5].

12. This is an annual plant, according to Gerard, in which it differs from the tenth ſort: but Villars ſays it is perennial. The ſtems are not ſo trailing as in that, and the leaves are ciliate, underneath villoſe. Native of Provence, Spain and the Levant [6].

Villars has three ſpecies of Illecebrum. The firſt he calls *polygonifolium* or Knot-graſs leaved, and regards as a new ſpecies. He figures it in t. 16. and deſcribes it thus. Root ſingle, and pretty thick. Stems numerous, ſpreading on all ſides, decumbent, and ſometimes creeping; they are hard, round, ſmooth, and much branched. Leaves ſmall, elliptic, in pairs, very ſmooth and even, with four lanceolate bractes white as ſnow, approaching to the ſame length with the leaf, but narrower and more pointed. Flowers from the upper axils of the leaves, alternate, from three to five in number, involved in ſimilar bractes, but larger, and ſtill whiter. Flowers very ſmall, and having only five fertile ſtamens (as in n. 8.) without any barren filaments. It rather reſembles Knot-graſs than the following ſpecies, which ſeem to be allied to Herniaria.

2. I. ſerpyllifolium, which he makes ſynonymous with I. Paronychia of Linnæus (n. 10.)

Stems trailing, very numerous more ſimple, or leſs branched. Leaves round, ſmall, little villoſe, green, but turning red towards the end of ſummer, manifeſtly ciliate, oppoſite, with very ſmall membranaceous ſtipules at their baſe. Flowers in rounded or leafy parcels or heads, white as a ſnow-ball, at the ends of the ſtems and lateral branches: they have five fertile and five barren filaments, like the Herniarias.

3. I. capitatum, branching leſs than the two foregoing, and the little ſtems riſing two or three inches. Leaves gray, erect, with dirty-gray ſtipules. Flowers all terminating. The five barren filaments have not been obſerved, but we may preſume the flowers have them, from the near affinity between this and the preceding.

Theſe three are all perennial, and natives of Dauphiné.

13. Root annual. Stem upright, ſubpubeſcent, not at all white, a foot or a foot and half in height. Leaves ſubſeſſile, broad-lanceolate, acuminate, pubeſcent, but green on both ſides. Spikes ſmall, hirſute, white, not only from all the axils of the leaves, but alſo at the top, where they are glomerate without leaves. Native of Bengal, Java, &c. in the Eaſt Indies [7].

14. This very much reſembles I. Paronychia (n. 10.), but the flowers are not in terminating heads, but ſcattered and cluſtered all over the ſtem, with bractes not longer than the flowers. Stamens connected at the baſe by a five-toothed pitcher, the teeth placed between the filaments. Styles two. It has the leaves of Paronychia, but narrower. Found in Arabia by Forſkahl [8].

15. Root annual. Stems from a foot to eighteen inches long, decumbent, round, jointed, and frequently putting out roots at the joints. Leaves oppoſite, very like thoſe of Blitum minus pallidum, except that they are not ſinuate at the end, but obtuſely mucronate, and one of each pair is ſcarcely more than half the ſize of the other. From the axils of theſe leaves, ſometimes both, ſometimes only one, proceed heads of flowers, the whole length of the ſtem, but eſpecially on the extreme branchlets; they are chaffy, prickly, and are compoſed of many pale juiceleſs ſcales, in which very minute and ſcarcely conſpicuous flowers lie concealed. Seed naked, round, compreſſed, leſs ſmooth and ſhining than that of Amaranthus, at firſt pale green, but afterwards becoming browniſh. About five ſcales or bractes belong to each flower.

Native of Buenos Ayres, whence ſpecimens in ſeed were ſent by Mr. Mylam, who was phyſician and ſurgeon to the South Sea Company there. From theſe ſeeds plants were raiſed in the Eltham garden, about the year 1732 or ſooner, which flowered and perfected their ſeeds in october [9].

16. Stem round, villoſe all over, dichotomous, which is not the caſe in the two next ſpecies. Leaves oppoſite, quite entire, even, but not ſmooth, very much veined, acute, ending at the baſe in petioles the length of the leaf, and ſomewhat hairy. Flowers axillary, white, and under them a three-leaved bractle, ſhorter than the flower. Filaments ſimple, ſhorter than the corolla. Germ compreſſed [10]. It reſembles the next ſpecies very much, but it is the ſtem in this, and not the flower, that is villoſe.

Native of America on ſea ſhores. Browne ſays that this little plant is found creeping in all the low lands, and dry ſavannas about Kingſton in Jamaica; that it generally grows in tufts, and ſpreads about ſix or eight inches from the root. He calls it hairy Rupture-wort, ſuppoſing it to be a Herniaria.

17. This plant puts out roots at every joint. Leaves wedge-form-lanceolate, acute, *ſeſſile*. Heads of flowers roundiſh, ſeſſile, numerous. Calyx (bractle) three-

[1] Hort. kew. [2] Linn. ſpec. [3] Hort. kew. [4] Gerard. [5] Hort. kew. [6] Linn. [7] Linn. mant. [8] Ibid. [9] Dillenius. [10] Linn. mant.

leaved, dry, permanent; outer-leaflet ovate, acuminate, concave, erect, the two side ones awl-shaped, fickled, acute, erect. Corolla (calyx). leaflets upright, dry, double the length of the bractæ; the two outer lanceolate-ovate, concave, the three inner lanceolate, convex, the middle one broadeſt. Filaments awl-ſhaped, upright, the length of the germ, which is roundiſh and compreſſed; ſtyle extremely ſhort, ſingle; ſtigma obtuſe, villoſe. Capſule cordate-orbiculate, compreſſed, crowned with the ſtyle and ſtigma. Seed orbicular, compreſſed [1].

The corolla, to ſharp-ſighted perſons, is pubeſcent. The nectary has five rays, jagged at the tip [2].

Native of America on the coaſt; now wild in Spain. Jacquin ſays, it is ſo abundant in Martinico in meadows, as to be a noxious weed.

18. Stem procumbent, rooting, purple, bifariouſly two-edged with a villoſe line, as in Veronica Chamædrys. The young leaves are ſerrate, but ſcarcely apparently ſo when adult [3].

Stems herbaceous, diffuſed, ſhort, as it were four-cornered, jointed, frequently creeping. Leaves ſubſerrate, ſeſſile, ſmooth, oppoſite. Flowers white, in roundiſh axillary heads, often two together [4].

Native of the Eaſt Indies, and in wet places about Canton in China.—It is an annual plant, and was introduced in 1778 by Monſ. Thouin. It flowers from july to october [5].

Forſkahl found ſix ſtamens in his *Alternanthera*, but Vahl remarked only five in the dried ſpecimens, and ſince it agrees with this plant both in the herb and fructification, he doubts not of their being the ſame.

19. This creeping plant ſpreads a great way among the graſs. The ſtem is pretty ſlender, and throws out a few fibrous roots at every joint. The whole plant has a reddiſh brown caſt; and ſomething the appearance of Purſlane [6].

Native of Braſil and Curaçoa. Very common about rock-river in Jamaica [7]. Sandy ſhores of South America [8].

Swartz places it among the Gomphrenas, on account of its having commonly two ſtyles, a two or three-leaved calyx, with a nectary and lanugo between the calyx and corolla; all indicating an affinity between this and G. globoſa.—See *Gomphrena vermicularis*.

20. Native of Spain.

21. Root woody, branched, gray. The whole plant is mealy and proſtrate. Stem branched, round, aſh-coloured; branches alternate, flexuoſe, purple at the joints. Leaves oval or roundiſh, blunt, minutely and ſcarce apparently acuminate, ſomewhat nerved, aſh-coloured underneath, ſpreading and finally hanging down, one inch long, and eight lines wide. Petioles ſcarcely any, edged by the leaf running along it. Spikes ſolitary, axillary, ſeſſile whilſt flowering, but peduncled whilſt fruiting; ovate, imbricate, three lines long. Flowers crowded very cloſe, imbricate, ſeſſile, of an herbaceous colour, two lines long. Calyx double: outer three-leaved, inner five-leaved, twice as long. Nectary a ſheath inſerted into the receptacle, five-parted, pellucid, concealing the germ. The calyx and nectary remaining, forming with the ſeed an ovate, imbricate ſpike. Seed roundiſh, compreſſed, rufous, gloſſy. It flowers and ripens its ſeeds in ſummer.

This plant has a double calyx as in Achyranthes, and ſome ſpecies of Illecebrum. It has no ſtipules, as in Achyranthes, and ſome ſpecies of Illecebrum. But it has the herb rather of this genus [9].]

PROPAGATION AND CULTURE.

7, 8, 10, 12. Theſe, which are natives of the South of Europe, may be propagated by ſeeds ſown on a bed of light earth the beginning of april. The plants will come up in may, when they ſhould be kept clean from weeds till the plants are fit to remove, when they ſhould be carefully taken up, planting ſome of each ſort in ſmall pots, and the other in a warm dry border, obſerving to water and ſhade them until they have taken new root; after which, thoſe that are planted in the full ground will require no other culture but to keep them clean from weeds; for in the ordinary winters of England they will live in the open air; but as theſe plants are ſometimes killed in ſevere winters, ſome ſhould be ſet in pots, to be placed in a common frame, where they may enjoy the open air in mild weather, but be ſcreened from froſt.

But as the ſeeds do not conſtantly ripen, they may alſo be increaſed by cuttings; which, if carefully taken off in may or june, and planted in a ſhady border, will in two months put out roots: in moiſt weather they may be tranſplanted, and afterwards treated as the old plants.

4, &c. The reſt being natives of the Eaſt or Weſt Indies, and other hot climates, are tender, and will not thrive in the open air in England; their ſeeds therefore muſt be ſown on a hot-bed in the ſpring, with Amaranthus, Gomphrena, and other tender plants: afterwards, if they are plunged into the tan-bed in the ſtove, their branches will put out roots, whereby they may be propagated in plenty. Where ſeeds cannot be obtained, they may be increaſed this way; and the perennial ſorts by cuttings.

DESCRIPTIONS, *&c.*

1. Stem arboreous, a fathom or more (eight feet, *Lour.*) in height, ſmooth all over. Branches trichotomous, wrinkled and angular, from ſpreading upright. Leaves aggregate, in threes or fours, elliptic (turbinate-ovate, *L.*) broader near the tip, acuminate, blunt, *L.*) quite entire, evergreen, paler underneath, often reflex, two inches long. Petiole very ſhort, channelled, gradually widening into the leaf. Flowers axillary, peduncled, ſolitary [a]. Germs eight or more [b]. Capſules ſix or eight, ovate-lanceolate, compreſſed a little, horizontal, of a ſubſtance like cork, rugged without, ſmooth and even within, having a ſtrong ſmell of Aniſe when rubbed. Seeds elliptic, ſubtruncated in front, lens-ſhaped, extremely ſmooth and even, gloſſy, rufous or cinnamon-coloured [c].

[1] Jacquin. [2] Linn. mant. [3] Ibid.
[4] Loureiro. [5] Hort. kew. [6] Browne.
[7] Swartz. [8] L'Heritier.

[a] Thunberg. [b] Loureiro. [c] Gærtner.

The whole plant, but especially the fruit, has a pleasant aromatic smell, and a sweetish subacrid taste. It is stomachic and carminative, and is used in the eastern countries in the cholic, rheumatism, &c. In China it is in frequent use for seasoning dishes, especially such as are sweet [a].

In Japan they place bundles and garlands of the Aniseed-tree in their temples before their idols, and on the tombs of their friends. They also use the powdered bark as incense to their idols. A branch put into the decoction of Tetraodon hispidum is supposed to increase the virulence of the poison. The bark finely powdered is used by the public watchmen to make a chronometer or instrument for measuring the hours, by slowly sparkling at certain spaces in a box, in order to direct when the public bells are to sound [b].

Native of China and Japan. Thunberg doubts whether this and the floridanum be really distinct species, or only varieties.

2. Stem arboreous; general appearance nearly as in the preceding species: flowers deep red: capsules considerably more numerous than in the former: viz. twelve or more [c]: petals from twenty to twenty-seven. Leaves, &c. extremely fragrant, as in the preceding. Native of Florida.

PROPAGATION AND CULTURE.

The Aniseed Tree may be propagated by seeds, if they can be procured; or by laying down the young branches; or by cuttings, which strike freely. It requires the same treatment as Gardenia.

ILU-MULLU. See *Spinifex*.

ILY. See *Arundo Bambos*.]

IMMORTAL FLOWER. See *Gnaphalium*.

IMPATIENS. (*Impatient of the touch. So named from the elasticity of the fruit.*)

DESCRIPTIONS, *&c.*

[These are herbaceous plants, with alternate, or sometimes, but rarely, opposite leaves, without any stipules. Peduncles axillary, one-flowered or many-flowered [*]. Linnæus divides the species into two sections, from this last circumstance; but Loureiro does not find, in any of the species which he examined, that the peduncles were always solitary, or always aggregate.

[*] Juffieu.

1. This

1. This is an annual plant, one foot high, upright, round, alternately branched, red. Leaves ſeſſile, ſmooth, ſubſerrate, or ſerrate-toothletted. Peduncles longer than the leaf, generally ſolitary. Flowers red-purple. Spur of the nectary awl-ſhaped, thick, very much bowed. Native of China[b].

2. This alſo is an annual plant. Leaves lanceolate, crenate, with a prominent dagger-point from each notch. Peduncles nearly the length of the leaves. Flowers the ſame ſize as in 1. Balſamina (n. 8); but the ſpur awl-ſhaped, almoſt the length of the peduncle. Native of the Eaſt Indies[c].

3. Leaves glaucous underneath. Peduncles alternate. Nectary larger than the petals. In other circumſtances it agrees with I. oppoſitifolia, from which however it appears to be different. Koenig ſent it from Ceylon[d].

4. 5. Natives of the Cape of Good Hope[e].

6. This is an upright plant, with a ſucculent jointed ſtem. Leaves ſeſſile, ſmooth, ſerrate-toothed. Branches ſingle from each alternate axil. Peduncles filiform, naked, commonly three from each axil, longer than the internodes. Flowers ſmall, with a nectary much ſhorter than the petals. Native of the iſland of Ceylon[f]. Annual.

7. This is alſo an annual plant. Stem a foot high, roundiſh, diffuſed. Leaves ſerrate, hiſpid, petioled, large, duſky green, ſweet-ſmelling. Flowers purple or white. Peduncles few, long. Spur three times as long as the petals, ſomewhat bowed. Capſule ovate, acuminate, hiſpid[g].

In its leafing this reſembles the next ſpecies, but the flowers are much ſmaller, with ſpurs five times longer and on very long peduncles. In Burman's figure, the peduncles are ſome ſolitary, others two, and others three together. The engraver, by miſtake, has placed ſome of them below the leaf. The Ceyloneſe call it *Kudaelu-kola*, from Kudaelu a ſwallow, and Kola a leaf[h].

Native not only of Ceylon, but of Cochinchina, where the inhabitants uſe a decoction of the leaves as a waſh to their head and hair, to which this plant, which is a common weed in their gardens, gives a very ſweet odour.]

8. Garden Balſamine or Balſam, is an annual plant riſing a foot and half high, and dividing into many ſucculent branches. Leaves long, ſerrate. The flowers come out from the joints of the ſtem, upon ſlender peduncles about an inch long, each ſuſtaining a ſingle flower; but there are two, three or four of theſe peduncles ariſing from the ſame joint.

[In its wild ſtate, it is about two feet high, with an upright, round, hiſpid, juicy, white ſtem, and aſcending branches. Leaves alternate, ſerrate, ſmooth, petioled. Peduncles long, ſubaggregate. Flowers red or white. Capſule ovate-oblong, lanuginous[i].

Native of the Eaſt Indies, China, Cochinchina, and Japan; the Japoneſe uſe the juice prepared with alum, for dying their nails red[k]. It was cultivated by Gerarde in 1596[l].

By culture this plant is very much enlarged, and becomes very branching. I have ſeen the ſtem ſeven inches in circuit, and all the parts large in proportion, branched from top to bottom, loaded with its party-coloured flowers, and thus forming a moſt beautiful buſh. The varieties which cultivation has produced in this elegant flower are numerous.] White, purple, red, ſtriped and variegated of theſe different colours, ſingle and double of each. Mr. Miller ſpeaks particularly of two varieties, which perhaps may belong to ſome of the other ſpecies. Firſt, the Immortal Eagle, a moſt beautiful plant from the Eaſt Indies. The flowers double, much larger than thoſe of the common ſort, ſcarlet and white, or purple and white; and there being many of theſe, the plant is very valuable. Secondly, the Cockſpur from the Weſt Indies; which has ſingle flowers, as large as the other, but never more than half double, but only with red and white ſtripes. This is apt to grow to a very large ſize before it flowers, which is very late in autumn, ſo that in bad ſeaſons there will be ſcarcely any flowers, and the ſeeds ſeldom ripen.

[9. Stem annual, a foot and half high, upright, round, with aſcending branches. Leaves ſmooth. Flowers ſcarlet, on one-flowered, ſubſolitary peduncles. Cultivated in Cochinchina, probably from China.

10. Stem annual, a foot high upright, jointed red, almoſt without branches. Leaves blunt, ſmall, ſmooth, thick, ſeſſile. Peduncles long, ſubſolitary. Nectary large, compreſſed, rolled into a ſpiral. Flowers ſcarlet, very handſome, but not ſweet. Capſule fleſhy. Cultivated in China[m].

11. Stem upright, jointed. Leaves ſmooth, acuminate, ſerrate, ending in the petioles. Peduncles dividing into three, or more rarely two equal pedicels, from the ſame point, like the umbellate plants, with an involucre of the ſame number of lanceolate deciduous leaves. Flowers large, with the horn of the nectary blunt, curved inwards, thick, ſcarcely the length of the flower. Burman ſays it is very long, and has ſo repreſented it in his figure. Native of Ceylon[n]: Mr. Miller adds, and of many parts of India, but that the flowers being ſmaller than thoſe of the common ſort, this is not worth cultivating for beauty. [Burman however ſays, that they are large and very elegant.

12. Root annual. Stem a foot high, upright. Stem and branches pale yellowiſh green, ſmooth and ſhining, ſomewhat tranſparent, thickeſt at the joints, ſucculent and brittle. Branches ſometimes oppoſite. Lower leaves ovate, uppermoſt elliptical or lanceolate, irregularly ſerrate, all ſmooth, petioled. Upper part of the ſtem flexuoſe, forming an obtuſe angle oppoſite to each leaf. Some of the branchings of the peduncles have bractes, and ſome not[o]. Flowers yellow; the lateral petals ſpotted with red, by cultivation changing to pale yellow or purpliſh[p]; theſe are blunt, ſlightly two-lobed, with an oval appendix at the baſe, about an inch in length, and above half an inch in breadth: the uppermoſt petal is roundiſh or elliptic, emarginate, blunt, quite entire, three lines and a half long, and five lines broad: the lowermoſt is tubular, round, gradually narrowing into a ſpur, reflex at the baſe, retuſe at the top, at bottom ovate, acuminate, an inch long, and half an inch wide, with ſcattered purple dots on the inſide. Filaments fleſhy, connected round the germ, thickening at top. Germ linear, ſtriated. Style ſhort, ovate, yellow. Stigma bluntiſh, yellow. Capſule an inch or more long, bellying at intervals. Seeds rather large, angular, ſtriated, ovate[q].

When the ſeeds are ripe, upon touching the capſule, they are thrown out with conſiderable force. Hence the latin names of *Impatiens* and *Noli tangere*, and the Engliſh names of *Quick in hand* (alive as it were in the hand) Gerarde calls it *Codded Arſmart*, and Parkinſon, Wild Mercury. *Touch me not.* The elaſticity of the ſeed-veſſel has furniſhed names in moſt of the European languages. In German it is called *Springſame, Springkraut*, &c. In Sweduiſh, *Springkorn*. In Daniſh, *Springkorn* or *Springurt*. In French, *Impatiente, ne me touchez pas*; and alſo *Balſamine jaune*. In Italian, *Erba impaziente, Balſamina gialla*. In Spaniſh, *No quieras tocarme, Balſamina amarilla*. In Portugueze, *Melindre nao me toques*.

In the day-time the leaves are expanded, but at night they hang pendant, contrary to what is obſerved in moſt plants which from a deficiency of moiſture, or a too great perſpiration from heat, commonly droop their leaves during the day[r].

The whole plant is conſiderably acrid, and no quadruped, except perhaps the goat, is ſaid to eat it. Notwithſtanding this it was formerly conſidered as diuretic and vulnerary, and was given to relieve the hæmorrhoids and the ſtrangury. Boerhaave regarded it as poiſonous. It is now configned wholly to the flower-garden, where however it is not often ſeen.

It

It is the only ſpecies of Impatiens wild in Europe. It is alſo found in Canada. With us it occurs in Wales, and the northern counties of England, in moiſt ſhady places, and by the banks of rivulets: as on the banks of Winander mere near Ambleſide, near Rydall Hall, and between both places, in Weſtmoreland; in Satterthwait pariſh, and by the ſide of Coniſton Lake in Lancaſhire. About Bingley in Yorkſhire. Flowering in july and auguſt.]

PROPAGATION AND CULTURE.

The ſeeds of theſe plants ſhould be ſown on a moderate hot-bed in the ſpring, and when the plants are come up about an inch high, they ſhould be tranſplanted on another moderate hot-bed at about four inches diſtance each way, obſerving to ſhade them from the ſun till they have taken new root; after which they ſhould have a large ſhare of free air admitted to them, at all times when the weather is favourable, to prevent their drawing up tall and weak: they will require to be often refreſhed with water, but it ſhould not be given to them in too great plenty; for as their ſtems are very ſucculent, they are apt to rot with much moiſture. When the plants are grown ſo large as to touch each other, they ſhould be carefully taken up with balls of earth to their roots, and each planted into a ſeparate pot filled with light rich earth, and plunged into a very moderate hot-bed under a deep frame, to admit the plants to grow, ſhading them from the ſun until they have taken freſh root; then they ſhould have a large ſhare of air admitted to them every day, and by degrees hardened, ſo as to bear the open air, into which part of the plants may be removed in july, placing them in a warm ſituation; where, if the ſeaſon proves favourable, they will flower and make a fine appearance; but it will be proper to keep part of the plants either in a glaſs caſe or a deep frame, in order to get good ſeeds, becauſe thoſe in the open air will not ripen their ſeeds until the ſummer proves very warm; and the plants in ſhelter muſt have a good ſhare of free air every day, otherwiſe they will grow pale and ſickly; nor ſhould they have too much of the ſun in the middle of the day, in very hot weather, for that occaſions their leaves hanging, and their requiring water, which is often very hurtful; therefore if the glaſſes are ſhaded in the middle of the day for three or four hours, the plants will thrive better, and continue longer in beauty than when they are expoſed to the great heat. Thoſe who are curious to preſerve theſe plants in perfection, pull off all the ſingle and plain-coloured flowers from the plants which they preſerve for ſeeds, leaving only thoſe flowers which are double, and of good colours; where this is carefully done, they may be continued without the leaſt degeneracy conſtantly.

The common ſingle ſort will ſpring in the open ground, and where the ſeeds ſcatter, they will come up the following ſpring. But ſuch ſelf-ſown plants do not come to flower ſo early as thoſe which are raiſed upon a hot-bed; they will continue, however, later in the autumn. But to have good flowers, the plants muſt be raiſed in a hot bed.

[Gerarde directs the ſeeds to be ſown at the beginning of april in a bed of hot horſe-dung, even as Muſk Melons, Cucumbers, &c. and replanted abroad from the ſaid bed, into the moiſt hot and fertile place of the garden, at ſuch time as they have gotten three leaves apiece.

Parkinſon ſays, it is a very tender plant, and muſt be ſown carefully in a pot of earth, and tended and watered in the heat of ſummer, and all little enough to bring it to perfection. In his time (1629) its native place was not known here, and the ſeeds were imported from Italy.

12. The other ſorts may be treated in the manner above directed, being annual plants from the ſame countries;] but if the ſeeds of the common European ſort be permitted to ſcatter, they generally ſucceed better than when they are ſown; for unleſs they are ſown in the autumn ſoon after they are ripe, they rarely grow. The plants require no care but to keep them clean from weeds, and thin them where they are too cloſe. It delights in a ſhady ſituation and moiſt ſoil.

DESCRIPTION, *&c.*

The root is as thick as a man's thumb, running obliquely in the ground; it is fleſhy, aromatic, and has a ſtrong acrid taſte, biting the tongue and mouth like Pellitory of Spain; the leaves ariſe immediately from the root; they have foot-ſtalks ſeven or eight inches long dividing into three very ſhort ones at the top, each ſuſtaining a triloobate leaf, indented on the border; the foot-ſtalks are deeply channelled, and when broken emit a rank odour. The flower-ſtalks riſe about two feet high, and divide into two or three branches, each being terminated by a pretty large umbel of white flowers, whoſe petals are ſplit; theſe are ſucceeded by oval compreſſed ſeeds, ſomewhat like thoſe of Dill, but larger. It flowers in june, and the ſeeds ripen in auguſt.

[Linnæus obſerves, that the floral leaves are oppoſite, and that there is a petiolary, membranaceous, ventricoſe ſtipule one within another.

The leaves, according to Lightfoot, have about five pinnas, the extreme one always divided into three lobes, and all ſharply ſerrate.

Fruit elliptic, emarginate at top and bottom, membranaceous winged. Seeds compreſſed, ſurrounded at the ſides with a very broad rim, and marked on the back with three white, acute angled ribs, not winged; the ventral part is flat, parted with two brown bowed fillets*.

Native of many parts of the Alps, Auſtria, Styria, Tyrol, Sileſia, Dauphiné; obſerved by Ray above the Grand Chartreuſe, and found by Mr. Lightfoot in Scotland, upon the banks of the Clyde in ſeveral places, particularly about Ardencaple; and in the iſle of Bute, near Mountſtewart.

The root is warm and aromatic; a ſudorific, diuretic and ſialagogue: recommended in dropſy, and debilities of the ſtomach and bowels; an infuſion of it in wine is ſaid to have cured quartans that have reſiſted the bark. When chewed it excites a copious flow of

* Gærtner.

saliva, with a warm and not disagreeable sensation in the gums, and frequently cures the rheumatic tooth-ache[b].]

PROPAGATION AND CULTURE.

This plant is cultivated in gardens to supply the markets. It may be propagated either by seeds, or by parting the roots: if you would propagate it by seeds, they should be sown in autumn soon after they are ripe, on a bed or border, in a shady situation; observing not to sow the seeds too thick, nor should they be covered too deep. In the spring the plants will appear, when they should be carefully weeded; and if the season should prove very dry, they should be now and then refreshed with water, which will greatly promote their growth. Toward the beginning of may, if you find the plants come up too close together, you should prepare a moist shady border, and thin the plants carefully, leaving them about six inches asunder: and plant those which you draw up into the border about the same distance apart every way, being careful to water them duly, if the season should prove dry, until they have taken root; after which time these plants (as also those remaining in the seed-beds) will require no other culture but to keep them clear from weeds; which may be easily effected, by hoeing the ground between the plants now and then in dry weather; and stirring the ground will be of great service to the plants. The following autumn these plants should be transplanted where they are designed to remain, which should be in a rich moist soil and a shady situation, where they will thrive much better than if too much exposed to the sun, or in a dry soil, where they will require a constant supply of water in dry weather. These plants must not be less than two feet distant every way. When they are rooted they require only to be kept clear from weeds; and in the spring, before they shoot, to have the ground gently dug between them, so as not to cut or bruise the roots. With this management they will continue several years, and produce seeds in plenty.

If you would propagate this plant by offsets, the roots should be parted at Michaelmas, and planted in a shady situation, at the same distance as has been directed for the seedling plants, observing to water them until they have taken root, after which they must be managed as the seedlings.

[IMPERATORIA. See *Astrantia*.]

INARCHING is a method of grafting, which is commonly called grafting by approach. This method is used when the stock intended to graft on, and the tree from which the graft is to be taken stand so near, or can be brought so near, that they may be jointed together. The manner of performing it is this: take the branch you would inarch, and having fitted it to that part of the stock where you intend to join it, pare away the rind and wood on one side about three inches in length. After the same manner cut the stock or branch in the place where the graft is to be united, so that the rind of both may join equally together, at least on one side, that the sap may meet; then cut a little tongue upwards in the graft, and make a notch or slit in the stock downwards to admit it; so that when they are joined, the tongues will prevent their slipping, and the graft will more closely unite with the stock. Having thus placed them exactly together, tie them with bals or other soft bandage, then cover the place with grafting clay, to prevent the air from drying the wound, or the wet from rotting the stock. Fix a stake in the ground, to which the stock or branch and graft should be fastened to prevent the wind from separating them.

In this manner they are to remain about four months, in which time they will be sufficiently united, and the graft may then be cut from the parent tree, observing to slope it off close to the stock; and if at this time the joined parts be covered with fresh grafting clay, it will be of great service to the graft.

This operation is always performed in april or may, that the graft may unite with the stock before the succeeding winter, and is commonly practised upon Oranges, Myrtles, Jasmines, Walnuts, Firs, Pines, and several other trees, which will not succeed so well by common grafting or budding. But although I have mentioned Orange trees, yet I would by no means advise this practice where the trees are designed to grow large, which, by this method, they rarely ever will do; and it is chiefly practised on Oranges as a curiosity, to have a young plant with fruit upon it, in a year or two from seed, by inarching a bearing branch into a young stock; but these plants are seldom long-lived.

11. Indigofera ſarmentoſa. *Dwarf Indigo.*
Lin. ſyſt. 677. *ſuppl.* 334. *Ait. hort. kew.* 3. 68.
Leaves ternate, ovate, ſubſeſſile, peduncles axillary, two-flowered or thereabouts, ſtem proſtrate, filiform.

12. Indigofera denudata.
Lin. ſyſt. 677. *ſuppl.* 334.
Leaves ternate, ovate, ſmooth, racemes peduncled, longer than the leaf, ſtem ſhrubby, upright.

13. Indigofera mexicana.
Lin. ſyſt. 678. *ſuppl.* 335.
Leaves ternate, panicle branched into ſpikes, ſtem ſhrubby.

14. Indigofera trita.
Lin. ſyſt. 678. *ſuppl.* 335.
Leaves ternate, ovate, acute, racemes ſhort, ſtem upright.

15. Indigofera coccinea.
Lour. cochinch. 457.
Leaves ternate, ovate-oblong, peduncles many-flowered, axillary, legumes round, bowed.

16. Indigofera rotundifolia.
Lour. cochinch. 458.
Leaves ternate, roundiſh, tomentoſe on both ſides, racemes ſhort, axillary, ſtem twining.

17. Indigofera bufalina.
Lour. cochinch. 458.
Leaves ternate, ovate, ſmooth, racemes axillary, legumes thick, villoſe, ſtem climbing.

18. Indigofera filiformis.
Lin. ſyſt. 678. *ſuppl.* 334.
Leaves quinate, oblong, villoſe, flowers in ſpikes, peduncled, peduncles and branches filiform, ſtem upright.

19. Indigofera coriacea. *Leathery-leaved Indigo.*
Ait. hort. 3. 68.
Ononis mauritanica. *Lin. mant.* 267. *Reich. ſyſt.* 3. 433.
Lotus mauritanicus. *Lin. ſpec.* 1091.
L. fruticoſus. *Berg. cap.* 226.
Leaves binate, obovate, mucronate, hairy, ſtipules awl-ſhaped, legumes ſtraight, ſmooth.

20. Indigofera digitata.
Lin. ſyſt. 678. *ſuppl.* 335.
Leaves digitate, racemes peduncled, ſtem ſhrubby.

21. Indigofera ſtricta.
Lin. ſyſt. 678. *ſuppl.* 334.
Leaves pinnate, ſmooth, oblong, racemes axillary, ſcarcely peduncled, ſtem ſhrubby, upright.

22. Indigofera fruticeſcens.
Lin. ſyſt. 678. *ſuppl.* 334.
Leaves pinnate, ovate, ſmooth, racemes axillary, peduncled, ſtem ſhrubby, upright.

23. Indigofera cytiſoides. *Angular-ſtalked Indigo.*
Lin. ſyſt. 678. *Ait. hort. kew.* 3. 68.
Pioralea cytiſoides. *Lin. ſpec.* 1076. *Comm. hort.* 2. 167. *t.* 84. (Lotus). *Pluk. phyt.* 185. *f.* 5. (Geniſta.)
Leaves quinate pinnate and ternate, racemes axillary, ſtem ſhrubby.

24. Indigofera fragrans.
Retz. obſ. 4. 29. *n.* 97.
Colutea ſiliquoſa. *Pluk. phyt. t.* 166. *f.* 1.
Leaves quinate, pinnate, leaflets ovate, hairy, the outmoſt larger, legumes four-cornered.

25. Indigoferum enneaphylla. *Trailing Indigo.*
Lin. ſyſt. 678. *Reich.* 3. 517. *mant.* 272. 571. *Retz. obſ.* 4. 29. *n.* 98.
Hedyſarum proſtratum. *Lin. mant.* 102.
Leaves pinnate, wedge ſhaped, in ſowens, ſtems proſtrate, ſpikes lateral.

26. Indigofera ſemitrijuga.
Vahl. ſymb. 1. 56. *Forſk. deſcr.* 137.
I. argentea. *Burm. ind.* 171.
Leaves pinnate, obcordate, in fives, legumes ſubſpiked, pendulous, toruloſe, ſtem proſtrate, ſuffruticoſe.

27. Indigofera pentaphylla. *Five-leaved Indigo.*
Lin. ſyſt. 678. *Reich.* 3. 518.
Leaves pinnate, oval, in fives, ſtems proſtrate, peduncles two-flowered.]

28. Indigofera glabra. *Smooth Indigo.*
Lin. ſpec. 1062. *ſyſt.* 678. *Reich.* 3. 518. *fl. zeyl. n.* 274. *amoen.* 1. 408.
Leaves pinnate and ternate, obovate, racemes very ſhort, legumes horizontal, columnar.

29. Indigofera hirſuta. *Hairy leaved Indigo.*
Lin. ſpec. 1062. *ſyſt.* 678. *Reich.* 3. 519. *amoen.* 1. 408. *fl. zeyl. n.* 272. *Burm. zeyl.* 37. *t.* 14. (Aſtragalus.) *Rheed. mal.* 1. 55. *t.* 30.

DESCRIPTIONS, *&c.*

At the end of the laſt century it was not known in Europe with certainty what plant produced the dye which was known to the Romans by the name of *Indicum*, and was ſo much uſed as a dye, &c. under the name of Indigo. It was cultivated, however, by Mr. Miller ſo early as the year 1731. Only five ſpecies were imperfectly known to Linnæus in 1763: and Mr. Miller has only the ſame number in the laſt edition of his Dictionary. Twenty-three ſpecies are enumerated in the fourteenth edition of the Syſtema Vegetabilium by Chevalier Murray: and our catalogue contains thirty-five ſpecies.

The Indigos are ſhrubs, underſhrubs or herbs. The leaves are in ſome few caſes ſimple, in more ternate, in moſt unequally pinnate, the leaflets in ſome joint d and awned at the baſe, as in *Phaſeolus*. Stipules diſtinct from the petiole. Peduncles axillary, one or two-flowered, but more frequently many-flowered, in ſpikes or racemes. Legume ovate, ſhort, (two-ſeeded in I enneaphylla.) The herb in moſt of the ſpecies yields

a blue dye [a]: which, however, is not peculiar to this genus; for many plants of this natural claſs abound with the ſame blue-colouring matter.

1. Stems determinately branched or proliferous, filiform, rugged with ſcars, with leafy branchlets. Leaves cluſtered, ſhort, acute, pubeſcent; varying, with the edge naked and coloured. Spike terminating, ovate, villoſe, with bractes the length of the calyxes between the flowers. Keel of the corolla ſhorter than the other petals, dark purple, with a long claw, and on each ſide a tooth. Native of the Cape of Good Hope [b].

2. This is a ſhrub, with tomentoſe ſilky branches. Leaves ſubſeſſile, remote. Rudiments of branchlets in the axils. Stipules minute, briſtle-ſhaped. Racemes three times as long as the leaf. Flowers numerous. Calyx ſilky-tomentoſe. Standard of the corolla very finely villoſe [c].

3. Stem ſhort, upright. Branches elongated, ſlender rot-like, decumbent, angular, finely villoſe. Leaves alternate, blunt, with a ſhort point, quite entire, keeled, on ſhort petioles, cloathed with ſhort white hairs preſſed cloſe to them. Flowers three or four, on ſhort pedicels in the axils of the leaves, red. Calyx five-cleft; ſegments acute, ciliate, ſpreading. Standard of the corolla cordate, acute, flat, bent back at an acute angle: wings bent down, flat, ovate, blunt, longitudinally incumbent on the keel, with their upper margins; keel the ſame length with the ſtandard, boat-ſhaped, compreſſed, green on the outſide and hairy, putting forth a ſharp elongated tooth at the middle of each ſide. Fruit globular, crowned with the ſtyle, ſnow-white, one-ſeeded [d].

Native of the Eaſt Indies, where it was obſerved by Koenig, who ſent it to Europe together with the ſeeds under this name, though it is deſcribed as a Hedyſarum by the younger Linneus in his Supplement. It has, however, the ſpur on each ſide of the keel, which determines it to be an Indigofera, nor has it the habit of the Hedyſarums; according to the remark of Vahl, who cultivated it at Copenhagen.

4. This was found at the Cape of Good Hope by Thunberg [e].

5. This is a ſhrub with an aſh-coloured bark, and very much branched. Branches attenuated, cut off at top, leafleſs, very thorny; ſpineſcent from the permanent peduncles: branchlets leafy, ſcattered on the older branches, ſhort. Leaves on very ſhort petioles; leaflets ſeſſile, hoary, equal, minute. Stipules aceroſe, minute. Peduncles from almoſt all the axils, permanent and becoming thorns, double the length of the leaf, bearing two or three flowers. Calyx villoſe, five-cleft. Standard of the corolla aſh-coloured on the outſide. Legumes ſomewhat columnar, villoſe. Native of the Eaſt Indies and Arabia [f].

6. Legumes linear, reflex, four-cornered with two oppoſite ſides broader than the two others [g]. Native of the Eaſt Indies.

7. Stem perennial, angular, with three ribs occaſioned by the petioles running down it, and ſomewhat rugged. Peduncle angular, longer than the leaves in a many-flowered raceme; pedicels very ſhort. Bractes caducous. The upper teeth of the calyx more divaricate than in the others. Corollas red: wings horizontal, converging with their upper margins; the keel has an awl-ſhaped, concave reflex tooth in the middle on each ſide. Germ channelled: ſtyle purple: ſtigma blunt. Seeds many [h].

Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1758. It flowers from july to ſeptember [i].

Perhaps this may be the glabra of Miller; which, as far as we can judge, is not the glabra of *Linneus*.

In the Amœnitates Academicæ it is deſcribed under the name of *Cytiſus pſoraloides*, as a ſhrub a foot high, with awl-ſhaped ſtipules; the leaves petioled, the leaflets all ſeſſile, lanceolate, almoſt naked; the ſpikes peduncled, upright, the calyxes pubeſcent, the flowers cloſely reflex.

8. This ſpecies is diſtinguiſhed by the whiteneſs of the ſtem and the under-ſide of the leaves. The flowers are red, not many (five to eight or nine) in a ſpike [k]. Native of the Cape of Good Hope, whence it was introduced by Mr. Fr. Maſſon in 1774. It flowers from july to ſeptember [l]: but its principal time of flowering, according to Mr. Curtis, is from the beginning of may to the middle of june.

9. This alſo is a native of the Cape, and was introduced by the ſame perſon at the ſame time. It flowers in march and april [m].

10. Stems a foot long, ſomewhat angular, almoſt naked. Leaves alternate, petioled, remote: leaflets equal, ſubmucronate, ſcarcely pubeſcent on the upper ſide, but more pubeſcent underneath, and paler: petiole ſpreading, the length of the leaflets. Stipules awl-ſhaped, patulous, ſhorter than the petioles. Spike axillary, lateral, oblong, without bractes. Peduncle many times longer than the leaves. Flowers dark purple. Native of the Cape of Good Hope [n].

11. This was found at the Cape by Thunberg, and alſo by Maſſon, who introduced it at Kew in 1786. It flowers in june [o].

12. This alſo was found at the Cape by Thunberg.

13. This is a ſhrub, with ruſeſcent, pubeſcent branches. Leaves remote, petioled: leaflets ovate, naked, almoſt equal, ſubſeſſile. Stipules ovate, minute. Panicle terminating, compoſed of eight or nine pedunculed ſpikes. Found in New Granada by Mutis [p].

14. Stem upright, green, having the appearance of I. Anil, branched at bottom. Leaves petioled. Racemes lateral, ſhorter than the leaves, upright, red, like thoſe of I. Anil. Native of the Eaſt Indies [q].

15. Stem ſhrubby, manifold, almoſt upright, branched. Leaves blunt, pubeſcent, ſmall. Calyx five-cleft, with the upper edge cut off, gaping. Corolla ſcarlet, with two long reflex ſpurs to the keel. Legume long, ſlender. Native of China about Canton.

16. Stem herbaceous, filiform, hairy. Leaves ſharpiſh at the tip. Stipules awl-ſhaped. Corollas yellow, with two long, awl-ſhaped, curved ſpurs to the keel. Legume oblong, flat, acuminate, ſmooth, two-ſeeded. It is allied to I. procumbens (n. 30.) Native of China about Canton.

17. Stem ſuffruticoſe, round, long, ſmooth. Flowers in both axillary and terminating racemes, on a long common peduncle. Calyx two-lipped, five-cleft, ſpreading. Corolla white-purple, with the keel repelling the ſtandard by two callous teeth put forth above the baſe. Legume long, ſtraight, ſomewhat compreſſed. Seeds ovate. Native of Cochinchina [r].

11. Found at the Cape of Good Hope by Thunberg [s].

19. In Linneus's ſpecies plantarum this plant is deſcribed under the name of *Lotus mauritanicus*, as a ſmall ſhrub, with filiform rigid branches. Leaves petioled, with white hairs ſcattered over both ſides. Stipules the ſize of the leaves, lanceolate-ovate. Peduncles axillary, long, racemed. Legumes half as long again as the leaves. In the Mantiſſa, it was removed to the genus *Ononis*, and now in the Catalogue of the Royal Garden at Kew into this genus.

Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers in july and auguſt [t].

20, 21, 22. Theſe were found at the Cape of Good Hope by Thunberg [u].

23. This is thus deſcribed, as a ſpecies of Pſoralea, by Linneus, in his Species Plantarum. Shrubby, with angular branches. Lower leaves ternate, upper quinate-pinnate: leaflets oblong, hoary, mucronate, almoſt equal. Stipules awl-ſhaped; with two little briſtles at the baſe of the leaflets. Racemes longer than the leaves, with ovate, mucronate, deciduous bractes. Calyx a little ſhorter than the corolla. Standard of the

corolla

corolla upright. Legume ſubcylindric, with iſthmuſes ſeparating the ſeeds.

Native of the Cape of Good Hope. Introduced in 1774 by Mr. Francis Maſſon. It flowers in July.

24. Stems round, ſomewhat hairy. Leaflets hairy on both ſides, the end one obovate and larger than the others. Stipules lanceolate, acute, rough-haired. Peduncles longer than the leaf, axillary, bearing from three to five flowers. Calyxes white with hairs. Corolla red. Legumes linear, ſquare. Found in the Eaſt Indies by Koenig [a].

25. Plant depreſſed to the ground. Stems ſeveral, round, even, a palm in length, with the lower branches depreſſed. Leaves alſo depreſſed, ſpreading; leaflets ſeven, (ſometimes five or nine) alternate, bluntiſh, channelled, even, (frequently retuſe, ſmooth above, but have imbricate, tomentoſe, or aſh-coloured hairs underneath. Stipules membranaceous, patulous, bifid: *mant.* 1. 102.) Spikes axillary, ſeſſile, roundiſh. Calyx almoſt five-parted; the parts lanceolate-awl-ſhaped. Corolla dark purple, with the back of the ſtandard paler, and recurved little horns to the keel [b]. Legumes ovate-cylindric, even, equal, mucronate with the ſtraight piſtil. Seeds two [c]. Native of the Eaſt Indies.

It is twice deſcribed in the Mantiſſas under this name and that of Hedyſarum proſtratum [d].

26. This is a ſmall ſhrub, with round, ſimple branches, villoſe-hoary, as is the whole plant. Leaflets ſeſſile, mucronate; the end one larger. Stipules linear. Spikes axillary, longer than the leaves. Flowers ſomewhat remote, commonly from eleven to thirteen. Legumes oblong, ſmall, two-ſeeded. It reſembles the twenty-fifth and twenty-ſeventh in many circumſtances, but is ſufficiently diſtinct from both. Native of the Eaſt Indies and Arabia [e].

27. Herb depreſſed, extremely divaricate. Flowers red. It reſembles *I. enneaphylla* very much, but the peduncles are two-flowered, and the plant is double the ſize. Its native place is not mentioned [f].

28. This is an annual plant, with ſmooth leaflets, the end one larger [g]: generally five, ſeldom three. The ſtem alſo is ſmooth. Peduncles axillary, having frequently three alternate flowers. Legumes bent back at a right angle, with the peduncle horizontal [h].

Native of the Eaſt Indies.

29. Stem lofty, hairy. Leaflets ſeven, obovate, remote, the end one larger. Stipules briſtle-ſhaped, an inch long. Spikes upright, longer than the leaves, axillary, very hirſute. Calyxes and legumes woolly, pendulous. Petals caducous [i]. Native of the Eaſt Indies.

30. Stem herbaceous, villoſe. Leaflets nine, ſubpetioled, villoſe, the end one larger. Stipules lanceolate-awl-ſhaped, dry. Spikes longer than the leaves, thrice the ſize when in fruit. Legumes villoſe. The preceding differs from this, in having an upright ſhrubby ſtem, briſtle-ſhaped ſtipules, and extremely hirſute four-cornered legumes. Native of Arabia [k].

31. Stem ſuffruteſcent, ſomewhat even; branches alternate, the length of the ſtem. Leaves alternate, ſubſeſſile; leaflets nine or eleven, equal, acute, ſubpubeſcent, rolled back at the edge. Stipules aceroſe, minute. Racemes axillary, lateral, much longer than the leaves. Calyxes alternate, hoary. Corolla aſh-coloured purple on the outſide: keel with ſpurs [l].

Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers from june to october [m].

32. This has the habit and appearance of the next ſpecies. Leaflets oblong, bluntiſh, (the younger one ſharpiſh) naked above, hoary underneath, all equal. Racemes lateral, ſubſpiked, ſhorter than the leaves. Legumes declining, recurved, inclined to columnar, many-ſeeded, more gibbous at each future (opening by the receding of the upper future) mucronate [n].]

Mr. Miller ſays, it grows to the height of five or ſix feet (if this be his *ſuffruticoſa*); and that being a much larger plant, it will afford a greater quantity of Indigo from the ſame compaſs of ground than any of the other ſpecies, eſpecially if cut before the ſtalks grow woody; it will alſo grow on poorer land.

[Native of the Eaſt Indies; and very common in Jamaica, growing wild in all the Savannahs, where doubtleſs it had been cultivated in former times: for there, we often meet with ſome of thoſe Indigo-works, which were then built, and remain very perfect to this day. It is hardier than any of the other ſorts, and grows very luxuriantly even in the dryeſt Savanna lands; but it does not yield ſo much pulp; the dye, however, that is extracted from it, is generally the beſt, of a fine copperiſh caſt, and a cloſe grain [o].

33. This differs from the preceding, in the leaflets being obovate, blunt, naked on both ſides; the legumes columnar, ſtraight, but more gibboſe at the future, as in that, and ſubtoruloſe, in looſe minute racemes [p].

Thunberg deſcribes it thus. Stem filiform, ſubflexuoſe, angular, ſmooth, upright, a foot and half high, a little branched at top. Branches like the ſtem, alternate, upright. Leaflets in four pairs or more, very blunt with a point, ſmooth, very finely villoſe underneath, almoſt equal. Racemes from the axils of the leaves, when they begin to flower much ſhorter than the leaf, but becoming longer as they advance. Legumes drooping, ſubcolumnar, ſharp, ſtraight, very finely villoſe.

Specimens of this plant from different parts of India, Madagaſcar, Java, Ceylon, &c. vary very much, if they are all really the ſame ſpecies. The ſtem is higher or ſhorter, more or leſs hairy or ſmooth; the leaves have from four or five to eight pairs of leaflets, larger or ſmaller, more or leſs villoſe; the legumes are ſtraight or bowed, villoſe or ſmooth [q].

Linnæus, in his flora zeylanica ſays, that the leaves have nine or eleven pairs of leaflets, which are green; and that it is almoſt an exotic in Ceylon, but frequent in Paliacotta and Coromandel.

According to Loureiro it is ſpontaneous in China and Cochinchina, and is cultivated all over thoſe vaſt Empires.—He thus deſcribes it. Stem upright, ſimple, three feet high, ſtraight, columnar, ſmooth, branched. Leaves compoſed of about ſeven pairs of leaflets, which are ovate, quite entire, ſmooth, glaucous, on ſhort petioles. Racemes axillary, ſimple, upright. Calyx flattiſh, ſlightly five-cleft. Standard of the corolla oblong-ovate, aſcending, yellow; wings and keel red, the latter having a tooth on each ſide at the baſe. Legume long, ſlender, round, ſlightly bowed and toruloſe, ſmooth, pendulous, containing ſeveral cylindrical ſeeds.

Dr. Patrick Browne, beſides the Wild Indigo already mentioned, has two others which he calls the Indigo, and the Guatimala Indigo. The former ſeldom above two feet and a half in height, and ſeeming to divide rather than to branch in its growth: the latter commonly three or four feet high, throwing out many ſubereƈt branches as it riſes. This is much hardier, and affords a finer pulp, but it does not yield ſo great a quantity, and is only cultivated where the ſeaſons are not ſo certain, or in mixt fields. The former yielding more of the dye than either of the others, is generally preferred, though ſubject to many more miſchances.

Mr. Miller cultivated the Dyer's Indigo ſo long ago as the year 1731 [r].] He calls it Guatimala Indigo, and ſays it is an annual plant with us. [He has five ſorts in all, but not having deſcribed them, we are in ſome degree uncertain what ſpecies he intended. His ſuffruticoſa (n. 2.) is probably our thirty-ſecond ſpecies, *I. Anil.* His indica (n. 4.) is ſuppoſed to be our twenty-ninth ſpecies, or *I. hirſuta*. His glabra (n. 5.) may poſſibly be the ſame with the *glabra* of Linnæus; but as he only ſays it has ſmooth taper pods, and trifoliate leaves, we cannot determine it with any certainty. His I. caroliniana (n. 3.) cannot be the I. tinctoria or true Dyer's Indigo, if the leaves have five leaflets only, and the flowers are in very long, looſe ſpikes; but it is probably the ſame with one of the

[a] Retzius. [b] Vahl. [c] Ibid. [d] Linn. mant. [e] Vahl. [f] Linn. mant. 2. 272. [g] Linn. ſyſt. [h] Linn. ſeyl. [i] Linn. mant. [k] Linn. mant. [l] Linn. ſyſt. & ſeyl. [m] Hort. kew. [n] Linn. mant. 102. [o] Browne. [p] Linn. [q] Thunb. jap. [r] Hort. kew.

ſorts commonly cultivated in the Weſt Indies, which are not originally natives there, but tranſported from the Eaſt Indies.

The ancients were acquainted with the dye which we call Indigo, under the name of *Indicum*. Pliny knew that it was a preparation of a vegetable ſubſtance, though he was ill-informed both concerning the plant itſelf, and the proceſs by which it was fitted for uſe. From its colour, and the country from which it was imported, it is denominated by ſome authors *Atramentum Indicum*, and *Indicum nigrum*[1].

Even at the cloſe of the ſixteenth century it was not known in England what plant produced Indigo. For in the Remembrances for maſter S. by Richard Hakluyt in 1582, he was inſtructed "to know if "*Anile*, that coloureth blew, be a natural commodity "of thoſe parts (Turkey), and if it be compounded "of an herb—to ſend the ſeed or root, with the "order of ſowing, &c.—that it may become a na"tural commodity in the realme, as *Wood* is, that "the high price of foreign Woad, may be brought "down[2]."

Gerarde, in 1597, is wholly ſilent about it, and ſo is Johnſon in 1632. Parkinſon however, in 1640, treats largely of it. He calls it *Indico* or *Indian Woade*, and gives a figure of the leaf from De Laet. He then deſcribes it, firſt from Francis Ximenes in De Laet's deſcription of America: and ſecondly, from Mr. William Finch, a London Merchant, in Purchas's Pilgrims. (B. 4. C. 4. p. 429.)

Even in 1688, Mr. Ray ſays, it was not agreed among botaniſts, what plant it is from which Indigo is made; but that the moſt probable opinion was, that it is a leguminoſe ſhrub, allied to Colutea. He deſcribes it from Hernandez and Marcgraaf; and ſubjoins that of the *Ameri* from the Hortus Malabaricus. *Nil* or *Anil* is the American name. It is *Nile* alſo in Arabic. The Portugueze have adopted their *Anil* or *Anileira* from the American. The other European nations generally call it *Indigo*. In Chineſe it is *Tien Laam*, which ſignifies Sky Blue.

Method of manufacturing Indigo in the Weſt Indies.

The works for ſteeping and fermenting the Indigo conſiſt of three or five ſquare ciſterns or vats, well cemented, terraſſed and ſeaſoned. They are made gradually ſmaller, and ſo ſituated as to have the top of the ſecond and third on a line with the bottom of the firſt, or a little lower; and the top of the fourth and fifth on a line with or lower than, the bottom of the ſecond and third. The firſt is called the *Steeper*, and is generally made about eight or ten feet ſquare, by four deep, and opens into the ſecond and third by round holes, made cloſe to the bottom, ſo as to diſcharge all the tincture readily. The ſecond, or ſecond and third vats are called the *Beaters*. If there be only one, and the liquor is to be worked up with hand buckets, it ſhould be eight or ten feet ſquare, and ſix feet deep: but if there be two, and the tincture is to be beaten with an engine, they ſhould be ſo deep as to hold all the liquor a good way below the main or horizontal axis into which the buckets are fixed; and the walls ſhould be nearly as high over the rollers, as the ciſtern is deep below them, to prevent the tincture from being waſted. After the liquor is well beat, it is left to ſettle; and when the pulp is depoſited, the clear fluid is drawn off by a vent placed ſome inches above the bottom of each ciſtern: and the remainder is diſcharged into the fourth and fifth ciſterns, by convenient outlets, placed cloſe to the bottom. Theſe laſt ciſterns are ſmall; they are however generally made ſquare, and proportioned to the quantity of pulp ſuch works commonly produce at a time.

Theſe works being in good order, and the plants cut and carried to them, they are laid in the ſteeper, and when that is pretty full, boards are laid over them, ſupported by props, from the beams that overlay the ciſtern: theſe being well ſettled, they put in as much water as will cover the weed, and leave it to digeſt and ferment, until the greateſt part of the pulp is exſtracted; without letting the tender tops run to putrefaction. In the management of this point the judgment of the planter chiefly conſiſts; for if he draws off the water but two hours too ſoon, he loſes the greateſt part of the pulp; and if the fermentation runs but two hours too long, the whole is ſpoiled. They frequently therefore draw out a handful of the weed, and when they find the tops grow very tender and pale, and obſerve the ſtronger leaves to change their colour to a leſs lively pale, they draw off the liquor without delay. They ſoon learn to know this critical point, by the height of the fermentation, and grain of the tincture; of which they frequently beat a little in a ſilver cup, for that purpoſe.

The pulp being thus extracted, the tincture is diſcharged into the beaters, and there worked up by two or three negroes, each with a bucket, (or by an engine.) They agitate it, until the dye begins to granulate, or float in little flocculæ in the water; which ſeparation is greatly forwarded by a gradual addition of clear lime water. The different ſtages of this operation are diſtinguiſhed, by examining a ſmall quantity of the liquor in a ſilver cup, from time to time; and a little experience ſoon learns them to know when to ſtop by a ſingle drop upon the nail at any degree of height, as they would have their Indigo of a deep copperiſh blue, or of a paler colour.

The liquor is now left undiſturbed, until the flocculæ ſettle; then the water is diſcharged, and the magma or mud is ſet out by a lower vent into its proper receptacles. This is again, by ſome, put into a cauldron, and heated over a gentle fire, but not ſo as to boil, and then emptied into little bags to drain: by others it is not heated, but immediately put into the bags: by all, it is afterwards put into ſquare boxes, with the ſides not above four inches deep, that it may dry the ſooner, and without crumbling, which it is otherwiſe apt to do[3].

34. This reſembles the preceding, but the racemes are longer than the compound leaves, and the legumes are two-ſeeded[4]. The ſtem is weak; the leaflets oblong, pale green and ſmooth, the peduncles very long, and the flowers looſely diſpoſed; the legumes compreſſed, ſhort and roughiſh[5].

Native of the Eaſt Indies.

35. The whole plant is ſilky and glaucous. Stem ſuffruticoſe, upright, branched, round, from half a yard to three quarters of a yard in height, and gray. Branches alternate, ſtiff, round, finely ſilky and hoary. Leaves alternate, petioled, two-paired (ſeldom ternate), ſpreading, three inches long: leaflets oppoſite, ſubſeſſile, (the end one larger and petioled); quite entire, bluntiſh, the older ones ſubemarginate, the midrib raiſed only underneath; finely ſilky, glaucous, ſpreading, flat, from twelve to fifteen lines in length, and from ſix to eight lines in breadth. Petioles round on one ſide, grooved on the other. Racemes axillary, ſolitary, upright, ſhorter than the leaves, an inch and half long. Flowers on ſhort, alternate, reflex pedicels, drooping. Calyx wheel-ſhaped, five-cleft, acute, pubeſcent, the two upper teeth more remote. Corolla blood-red-purple: petals nearly equal, larger than the calyx: ſtandard roundiſh, reflex, concave, pubeſcent on the outſide, ſeſſile; wings oblong, blunt, on ſhort claws, looſe; keel two-petalled, clawed, ovate, compreſſed, ſcarcely ſhorter than the wings, with a proceſs at the baſe on each ſide filling up the cavity left by the wings, pubeſcent on the outſide. Filaments connected very high up, ſcarcely longer and ſhorter alternately, and very little ſhorter than the keel: anthers roundiſh, acuminate, two-celled, larger on the longer filaments. Legume columnar, jointed in a manner, like a necklace, tomentoſe, hoary, ſix lines in length. Seeds few (three or four), ſeparated by membranes, roundiſh, bay coloured[6].

Gouan deſcribes the ſtem as three feet high and angular, ſtrigoſe with crowded hairs preſſed to it, and rugged when handled from above downwards. The branches alſo are angular. The lower ſtem-leaves and

[1] Robertſon's India, p. 353. [2] Voyages 2. 161. edit. 1599. [3] Browne. [4] Linn. [5] Trew Ehret. [6] L'Heritier.

the

the inner branch-leaves are ſimple, obovate and aſh-coloured, rugged with hairs preſſed cloſe, on petioles equal to the leaf: the other leaves to the middle of the ſtem and branches are ternate, with ovate leaflets, acuminate both ways, the outmoſt larger than the two others: thoſe which terminate the ſtem and branches are like the others, but quinate. Petioles equal to the leaflets, three-ſided at the baſe, their edges and midrib running down the ſtem and branches, ſo that the branches ſeem to be three-ſided a little below the baſe of the petioles. Racemes an inch long, from the axils of the ternate and quinate leaves. Flowers in each raceme from nine to twelve, purple, very ſmall as in *I. tinctoria*. Legume cylindric, jointed or knobbed at the ſeeds; joints globular, the outmoſt mucronate. Seeds one, two or three, ſubglobular, not cylindric, flat at top and bottom, as in *I. tinctoria* Linneus ſays, that the legumes have uſually three ſeeds in them. According to him it is a native of the Eaſt Indies. Monſ. L'Heritier ſays, it is a native of Egypt, and that he had the ſeeds from Alexandria by Jean Baptiſte Mure, Conſul-general in Egypt, in the year 1783: and that he had ſince been informed by Profeſſor Lotiche Desfontaines that it is cultivated abundantly in the kingdom of Tunis for dyeing, but is not indigenous there. The Arabs call it *Hab-nil*.

Whether the plant deſcribed by Monſ. L'Heritier and Monſ. Gouan be the ſame is not quite certain. The former refers to Linneus's mantiſſa; and Vahl, who refers to Gouan, refers alſo to the ſame work of Linneus's. Linneus himſelf refers to the *ſuffruticoſe* of Miller, *n.* 2. and Sloan's Jamaica, *t.* 176. *f.* 3. for which ſee *n.* 32.

In the Kew catalogue, *I. argentea* is ſaid to be a native of the Weſt Indies, and to have been introduced in 1776, by Mr. Gilbert Alexander.

General Remarks.

There is much confuſion in the ſpecies yet to be cleared up: and we are yet uncertain whether the plants cultivated in different countries for dyeing, be really diſtinct ſpecies or only varieties. Gærtner has a ſpecies which he received from our Hudſon, and calls *Ind. ſumatrana*, but he gives no ſpecific difference.

An attention to the following circumſtances, will aſſiſt in diſcriminating the ſpecies already known.

Shrubby. 1, 2. 5. 7. 8. 9. 12, 13. 15. 19 to 23. 29.
Suffruticoſe or Underſhrubby. 17. 26. 31 to 35.
Herbaceous. 3. 4. 10, 11. 16. 25 to 28. 30.

Moſt of thoſe are perennial, but 3 *and* 28 *are annual.*

Leaves ſimple in 1. 2. 3. 4.
ternate in 5 to 17.
pinnate in the reſt.

Of theſe laſt, ſome are quinate, or have only two pairs of leaflets, beſides the odd one: as 18, 19. 24. 26, 27.

In 23. 28 *and* 35. *ſome of the leaves are quinate and others ternate.*

The twentieth ſpecies has digitate leaves.

Stipules minute, briſtle-ſhaped, in 2 and 29.
minute, aceroſe, in 5 and 31.
minute, ovate, in 13.
lanceolate-ovate, in 19.
lanceolate-acute, in 24.
lanceolate-awl-ſhaped, in 30.
awl-ſhaped, in 7. 10. 16. 23.
linear, in 26.
bifid, in 25.

Inflorescence generally in a ſpike or raceme.
Spike. 1. 8 to 10. 18. 25, 26. 29, 30.
Raceme. 2. 7. 12. 14. 16, 17. 19 to 23. 28. 31 to 35.
Panicle. 13.

On axillary peduncles:
Two-flowered. 27.
Two or three-flowered. 5. 11.
Three or four-flowered. 3.
Many-flowered. 15.
Axillary ſeſſile. 6.

Bractes in moſt of the ſpecies: except 10.

Length of the calyx, in 1.
Caducous, in 7.
Deciduous, ovate-mucronate, in 23.

Colour of the corolla, moſtly red or purple:
Red. 3. 5. 7. 8. 14. 24. 27. 33.
Red purple. 35.
Dark purple. 1. 10. 25.
Very pale purple. 17. 32.
Aſh-coloured purple. 31.
Scarlet. 9. 15.
Yellow. 16.

The plants are unarmed, or without thorns and prickles, except in *n.* 5. which is thorny.

PROPAGATION AND CULTURE.

The ſpecies firſt known in Europe are natives of the Eaſt Indies, and may be propagated by ſeeds. The ſeeds muſt be ſown in a hot-bed, early in the ſpring, and when the plants come up two inches high, they ſhould be tranſplanted into ſmall pots filled with good freſh earth, and the pots muſt be plunged into a hot-bed of tanner's bark: when the plants have obtained ſome ſtrength, the glaſſes muſt be raiſed in the day time. The perennial ſorts may alſo be increaſed by cuttings.

The ſpecies natives of the Eaſt Indies are, 3. 5. 6. 14. 24, 25, 26. 28, 29. 32, 33. 34.

Moſt of the new ſpecies are from the Cape of Good Hope. (1. 4. 7 to 12. 18 to 23. and 31.) Theſe require only the protection of a dry ſtove or glaſs caſe, and may be propagated by cuttings, though ſome of them do not ſtrike very readily. Several of them ripen their ſeeds in Europe, and therefore may be alſo propagated that way.

Several ſpecies are natives of Egypt or Arabia, as 2. 5. 26. 30. 35. Two are natives of China, 15 and 16. One of Cochinchina, *n.* 17. And *n.* 13. of New Granada in Spaniſh America. All therefore are the growth of hot climates; and not one of Europe.

Culture of Indigo (*n.* 33.) *in the Weſt Indies.*

Indigo ſeems to thrive beſt in a free rich ſoil, and a warm ſituation; but to anſwer the planter's toil to his ſatisfaction, it ſhould be cultivated where it may be frequently refreſhed with moiſture.

Having firſt choſen a proper piece of ground, and cleared it, hoe it into little trenches, not above two inches, or two inches and a half in depth, nor more than fourteen or fifteen inches aſunder. In the bottom of theſe, at any ſeaſon of the year, ſtrew the ſeeds pretty thick, and immediately cover them. As the plants ſhoot, they ſhould be frequently weeded, and kept conſtantly clean, until they ſpread ſufficiently to cover the ground.

Thoſe who cultivate great quantities, only ſtrew the ſeeds pretty thick in little ſhallow pits, hoed up irregularly, but generally within four, five or ſix inches of one another, and covered as before. Plants raiſed in this manner are obſerved to anſwer as well, or rather better than the others, but they require more care in the weeding. They grow to full perfection in two or three months, and are obſerved to anſwer beſt when cut in full bloſſom. The plants are cut with rape-hooks, a few inches above the root, tied in loads, carried to the works, and laid by ſtrata in the ſteeper.

The culture of Indigo has been greatly neglected among the Engliſh coloniſts, though no part of the world affords a better ſoil, or more commodious ſituations for that purpoſe than Jamaica. They have begun however to plant there of late years.

Seventeen negroes are ſufficient to manage twenty acres of Indigo; and one acre of rich land, well planted, will, with good ſeaſons and proper management, yield five hundred pounds of Indigo in twelve months: for the plant ratoons and gives four or five crops a year; but muſt be replanted afterwards*.]

Mr. Miller is of opinion that the planters of Indigo ſow their ſeeds too thick, whereby the plants are drawn up with ſlender ſtems, not ſufficiently furniſhed with leaves, and thoſe leaves not ſo large and ſucculent, as if the plants were allowed a greater ſhare of room. It is a common obſervation of the cultivators of Woad,

* Browne.

that

that when the plants ſpire, and have narrow thin leaves, they produce little dye; they not only therefore make choice of rich ſtrong land, but are careful to thin the plants, that they may have room to ſpread, and produce large ſucculent leaves. If the planters of Indigo in America would imitate the cultivators of Woad in this particular, they would certainly find their advantage in ſo doing.

Another point in which they err is, letting the plant ſtand too long before they cut it; for the older it is, the drier and firmer are the ſtalks, and the leſs will be diſſolved by fermentation; nor will the fæces of old plants be near ſo beautiful. It is to be wiſhed therefore that the planters would try ſome experiments in the culture and management of Indigo, by ſowing thin, keeping the plants perfectly clean, and cutting them whilſt young and full of juice. But labour being dear in the Weſt Indies, the planters may object to the expenſe of cultivating Indigo in this manner. To avoid this, the ſeeds might be ſown with the drill plough; and by the uſe of the hoe plough, ten acres may be kept clean from weeds with a ſmall expenſe as one with the hand hoe; and by ſtirring the ground often, and earthing up the plants, they would grow much ſtronger, be leſs liable to be deſtroyed by inſects, and have larger and more ſucculent ſtalks and leaves.

Though all ſeaſons be good for ſowing Indigo, yet care muſt be taken not to do it in a dry time, becauſe it may be eaten by vermin, carried away by the wind, or choked by weeds: the planters therefore uſually chooſe a ſeaſon which promiſes rain, and then they are ſure of ſeeing the plant ſpring up in three or four days.

DESCRIPTION, *&c.*

This is a tree, with alternate leaves, a long ſpan in length, oblong, ſubcordate, on very ſhort petioles, quite entire, ſmooth, veined. Spikes (Racemes) axillary, ſolitary, ſmall, hirſute. Flowers ſmall, alternate, with ſmall bractes [a].

Native of the Society, Friendly and New Hebrides Iſles, &c. in the South Seas [b]; alſo in Amboina.

Forſter deſcribes it as a lofty tree, the thickneſs of a man's body, with a brown chinky bark: the branches woody, round, ſpreading, variouſly divided, brown, chinky. Leaves ſubdiſtich, ovate-oblong, ſcarcely cordate, blunt and retuſe, ſeldom acute, ſpreading, netted with abundance of veins, a ſpan long, and on young trees a foot. Petioles roundiſh, ſpreading, ſmooth and even, tranſverſely ſtriated, half an inch long. General peduncles axillary, ſubſolitary, round, ſpreading, covered with a black pubeſcence, a hand in length. Raceme filiform, quite ſimple. Pedicels very ſhort, ſcattered, cluſtered. Flowers duſky white, ſcarcely half an inch in length.

In Otaheite this tree is called *Hi*, and the fruit *Ratta*. In Mallicollo the name of the tree is *Nias*, and in Tanna, *Emmer*. In Cook's laſt voyage (1. 393.) the nuts are called *E-ffi*. The kernel of theſe, which is kidney-ſhaped, and about an inch in diameter, is eaten roaſted by the inhabitants of the Society and Friendly iſles, the New Hebrides, New Guinea, the Molucca iſles, &c. It is ſweetiſh, but leſs pleaſant than the Cheſtnut, harder and leſs farinaceous. The bark is aſtringent, and is uſed in the dyſentery. In New Guinea, they ſmear the heads of their arrows with the expreſſed reſinous juice [c].]

INOCULATING, or Budding. This is commonly practiſed upon all ſorts of ſtone fruit, in particular Peaches, Nectarines, Cherries, Plums, &c. as alſo Oranges and Jaſmines, and is preferable to any ſort of graſting for moſt ſorts of fruit. The method of performing it is as follows: you muſt be provided with a ſharp penknife, having a flat *haft* (the uſe of which is to raiſe the bark of the ſtock, to admit the bud) and ſome ſound baſs mat, which ſhould be ſoaked in water to increaſe its ſtrength, and make it more pliable; then having taken off the cuttings from the trees you would propagate, you ſhould chooſe a ſmooth part of the ſtock about five or ſix inches above the ſurface of the ground, if deſigned for dwarfs, and for half ſtandards at three feet; but for ſtandards, they ſhould be budded ſix or more feet above ground; then with your knife make an horizontal cut acroſs the rind of the ſtock, and from the middle of that cut make a ſlit downwards about two inches in length, ſo that it may be in the form of a T; but you muſt be careful not to cut too deep, leſt you wound the ſtock: then having cut off the leaf from the bud, leaving the foot-ſtalk remaining, you ſhould make a croſs cut about half an inch below the eye, and with your knife ſlit off the bud, with part of the wood to it, in form of an eſcutcheon: this done, you muſt with your knife pull off that part of the wood which was taken with the bud, obſerving whether the eye of the bud be left to it, or not, for all thoſe buds which loſe their eyes in ſtripping, ſhould be thrown away, being good for nothing; then having gently raiſed the bark of the ſtock where the croſs inciſion was made, with the flat haft of your penknife clear to the wood, you ſhould thruſt the bud therein, obſerving to place it ſmooth between the rind and the wood of the ſtock, cutting off any part of the rind belonging to the bud, which may be too long for the ſlit made in the ſtock; and ſo having exactly fitted the bud to the ſtock, you muſt tie them cloſely round with baſs mat, beginning at the under part of the ſlit, and ſo proceed to the top, taking care that you do not bind round the eye of the bud, which ſhould be left open.

When your buds have been inoculated three weeks or a month, you will ſee which of them have taken; thoſe of them which appear ſhrivelled and black, being dead, but thoſe which remain freſh and plump, you may depend are joined; and at this time you ſhould look to the bandage, which, if not done in time, will pinch the ſtock, and greatly injure, if not deſtroy, the bud.

The march following you muſt cut off the ſtock about three inches above the bud, ſloping it that the wet may paſs off, and not enter the ſtock; to this part of the ſtock left above the bud, it is very proper to faſten the ſhoot which proceeds from the bud, and would be in danger of being blown out, if not prevented; but this muſt continue no longer than one year, after which it muſt be cut off cloſe above the bud, that the ſtock may be covered thereby.

The time for Inoculating is, from the middle of June

[a] Linn. ſuppl. [b] Forſt. flor. [c] Forſt. eſcul.

until the middle of auguſt, according to the forwardneſs of the ſeaſon, and the particular ſorts of trees to be propagated; but the time may be eaſily known, by trying the buds, whether they will come off well from the wood. However, the moſt general rule is, when you obſerve the buds formed at the extremity of the ſame year's ſhoots, which is a ſign of their having finiſhed their ſpring growth.

The firſt tree commonly inoculated is the Apricot, and the laſt the Orange-tree, which ſhould never be done until the middle of auguſt; and in doing this work, you ſhould always make choice of cloudy weather; for if it be done in the middle of the day, in very hot weather, the ſhoots will perſpire ſo faſt, as to leave the buds deſtitute of moiſture; nor ſhould you take off the cuttings from the trees long before they are uſed; for if you are obliged to fetch your cuttings from ſome diſtance, as it often happens, you ſhould then be provided with a tin box or caſe, having a ſocket about ten inches long, and a cover to the top, which muſt have five or ſix holes; in this ſocket you ſhould put as much water as will fill it about two or three inches high, and place your cuttings therein in an upright poſition, ſo that that part which was cut from the tree may be ſet in the water, and ſo faſten down the cover to keep out the air; and the holes in the cover will be ſufficient to let the perſpiration of theſe branches paſs off, which, if pent in, would be very hurtful to them; you muſt alſo be careful to carry it upright, that the water may not reach to the buds; for it is a very wrong practice in thoſe who throw their cuttings all over in water, which ſo ſaturates the buds with moiſture, that they have no attractive force left to imbibe the ſap of the ſtock, whereby they very often miſcarry.

But before I leave this head, I beg leave to obſerve, that though it is the ordinary practice to diveſt the bud of that part of the wood which was taken from the ſhoot with it; yet, in many ſorts of tender trees, it is beſt to preſerve a little wood to the bud, without which they often miſcarry. The not obſerving this, has occaſioned ſome people to imagine, that ſome ſorts of trees are not to be propagated by Inoculation; whereas, if they had performed it in this method, they might have ſucceeded, as I have ſeveral times experienced.

34. Inula fruticoſa. *Shrubby Inula.*

Mill. dict. n. 15.

Leaves lanceolate acute three-nerved underneath, calycine ſcales acute, ſtem ſhrubby.

DESCRIPTIONS, &c.

[The Inulas are in general herbaceous plants, with exception to the 28th, 29th, 30th, 32d and 34th ſpecies, which are ſhrubby. The 8th, 9th, 10th, 11th and 12th are annual. Leaves ſimple, alternate. Flowers yellow (except n. 28), axillary or terminating, frequently in corymbs. They agree in ſo many circumſtances with the Aſters, that Tournefort, Haller, Scopoli and others do not ſeparate them. The florets in the ray are more numerous in this genus, and of a yellow colour. Linneus's eſſential character, of two briſtles at the baſe of the anthers, ſo far from being common to all the ſpecies, is not found even in the majority, according to Gærtner: they are however ſo ſmall in ſome ſpecies as to eſcape common obſervation[a].

1. Elecampane has a perennial, thick, fuſiform, brown, branching, aromatic root. According to ſome it is biennial. It is one of the largeſt of our herbaceous plants, being from three to five or ſix feet high, with the ſtem ſtriated and downy, branched towards the top. Lower leaves on footſtalks, lanceolate, a foot long, and four inches broad in the middle: [upper embracing, ovate-lanceolate, wrinkled, ſerrated or toothed, deep green and ſlightly hairy above, whitiſh green and thickly downy beneath. Flowering heads very large, ſingle, terminating the ſtem and branches. Outer ſcales of the calyx ovate-lanceolate, like the leaves; inner bluntly ovate, tomentoſe. Florets all yellow, thoſe of the ray narrow, linear, from an inch to an inch and half in length, with three ſharp teeth at the end[b]. Seeds columnar, four-cornered, obſcurely ſtriated, ſmooth, cinnamon-bay-coloured, with the rim of the umbilicus cartilaginous and white. Pappus, egret or down white, twice as long as the ſeed, appearing to be capillary[c]; but when viewed with a glaſs, finely toothed on one ſide, ſhorter than the florets, ſeſſile[d]. Receptacle wide, ſmooth, hollow-dotted, or with very ſmall angular holes ſcarce ſenſibly toothletted at the edge[e].

Native of Japan, Denmark, Germany, Flanders, Switzerland, Auſtria, France, Piedmont, Spain, and Britain. With us in Eſſex frequent, in Norfolk not uncommon, Mettingham in Suffolk, near Madingley in Cambridgeſhire, Bugden, Ripton and Warboys in Huntingdonſhire, Dunſtable and Pertenhall in Bedfordſhire, ſide of Bredon-hill, and other places in Worceſterſhire, about St. Ives in Cornwall, &c. Between Denbigh and St. Aſaph, Wales. In Scotland it is a doubtful native.] It flowers in june and july, and the ſeeds ripen at the end of auguſt.

[The root is eſteemed a good pectoral, and a conſerve of it is recommended in diſorders of the breaſt and lungs, as good to promote expectoration. An infuſion of it freſh, ſweetened with honey is ſaid to be an excellent medicine in the hooping cough. A decoction of it, applied outwardly, is ſaid to cure itch. Bruiſed and macerated in urine, with balls of aſhes and whortle berries, it dyes a blue colour. A decoction of it cures ſheep that have the ſcab[f]; hence it is called in ſome counties *Scab-wort*: in others it has the name of *Horſe heale*[g], doubtleſs from its reputed virtues in curing the cutaneous diſeaſes of horſes. The official name is *Enula campana*, whence evidently our Engliſh *Elecampane* is derived. In German it is *Alant, Aland, Alantwurz, Olant, Oltwurz, Helenenkraut, Glockenwurz, der groſſe Heinrich.* In Dutch, *Gewoon Alant, Alantſwortel.* In Daniſh. *Aland, Alandſroed, St. Ellens roed.* In Swediſh, *Alandſrot.* In French, *L'Enule aunée, Taunée, l'Enule-campane, l'herbe contre la gale.* In Italian, *Enula, Enula campana, Ella, Elenio.* In Spaniſh and Portugueze, *Enula campana, Ala.* In Ruſſian, *Dewjatſchik, Deweſil, Oman, Krun.*

2. Stem ſimple, hairy. Leaves ſoft; root-leaves large; ſtem-leaves embracing; all very hairy above, beneath whitiſh. Flowers one or two, peduncled[h]. The root is perennial, with an aromatic ſmell and taſte; whence the trivial name.]

The ſtems are about two feet high, divided into ſeveral branches, with a few ſcattering yellow flowers,

[a] Juſſieu and Gærtner. [b] Woodw. Mſs. [c] Gærtner.
[d] Woodw. Mſs. [e] Gærtner. [f] Withering and Lightfoot.
[g] Gerarde. [h] Lin. ſpec. ſyſt. & mant.

which

which appear in july, but are rarely followed here by ſeeds.

[Native of the South of Europe, as Provence, Narbonne, Italy and Sicily. Ray obſerved it about Meſſina.—Mr. Miller cultivated it in 1759[i].

3. This has been confounded with the preceding, from which however it differs conſiderably. The root has no ſmell, but is acrid, and conſiſts of a bundle of round dirty white fibres, iſſuing from a thicker head. Stem uſually ſingle, upright, round, purpliſh, villoſe, leafy, a foot and half high, branching only at top into few-flowered peduncles. Leaves oblong-lanceolate, acute, obſcurely ſerrate, wrinkled, deep green with very ſhort hairs above, paler and veined with longer hairs beneath, the lower ones attenuated into the petiole, the upper ones ſeſſile with ſome ſmell. Flowers ſweet-ſmelling. Inner ſcales of the calyx erect and purpliſh, outer green ſhort and reflex. Radial corollets ſhorter than the calyx and three-toothed. Anthers briſtly. Seeds black with white cilias[k].

Native of the South of Europe, flowering from june to auguſt. Cultivated by Mr. Miller in 1758[l].

4. Root perennial. The whole is hirſute. Stem a foot or eighteen inches high, upright, hard, ſtiff, hairy, dividing into two or three branches. Leaves narrow, three-nerved, very obſcurely, if at all, ſerrate; the lower ſubpetioled, alternate, lanuginoſe. Flowers in a corymb, of a fine yellow or golden colour, large but ſmaller than in the firſt ſort. Corollets of the ray, three-toothed or ſometimes quite entire[m].] Mr. Miller ſays, the flowers are ſmall, and are in cloſe cluſters; theſe appear in july, but ſeldom perfect ſeeds in England.

[Native of Auſtria, the South of France and Sileſia. Cultivated by Mr. Miller in 1759.]

5. Root perennial. Stem near two feet high, dividing in the upper part into two or three upright branches, or peduncles, each ſuſtaining one pretty large flower, of a deep yellow colour. Theſe are in beauty in july, but ſeldom ripen ſeeds here.

[It has the habit of *I. dyſenterica*, but the ſtem is loftier and more upright; the leaves narrower, and finely ſerrate. The variety β differs only in having the ſtem and under ſurface of the leaves more villoſe. The petals of the ray are very narrow[n].

It differs from the next ſellowing ſpecies, according to Krocker, in having a creeping root, the ſtem eighteen inches high, more diffuſed, round, jointed; the leaves four inches long, half an inch or even an inch in breadth, hiſpid about the edges; the flowers have the form of the After, are ſolitary, terminating, broader; the diſk wider, the ray ſhorter, both of a golden colour.

Native of Germany, Scania, Siberia, Piedmont.—Cultivated by Mr. Miller in 1759[o].

6. Root perennial, creeping, whitiſh, the thickneſs of a gooſe quill, with largiſh fibres. Stem from one to two feet high, upright, round, firm, ſolid, ſtriated, downy, branched more or leſs towards the top. Leaves alternate, ſet thickly together, ſpreading, oblong or lanceolate, obſcurely toothed, embracing the ſtem with their arrowhead-ſhaped baſe, underneath tomentoſe or downy, above ſomewhat hirſute, of a dull green colour. Branches like the ſtem, upright, the lateſt growing to the greateſt height. Flowers an inch or more in diameter, terminating, ſingle or two together, forming all together a ſort of corymb. Scales of the calyx numerous, awl-ſhaped, downy, frequently curved back at the end and coloured at the edge. Florets all yellow, exceedingly numerous in the diſk, numerous alſo, cloſe, linear, three-toothed in the ray. Briſtles at the baſe of the anthers very minute. Seeds rough with ſhort briſtles, crowned with a ſeſſile egret, of few ſimple rays, as long as the tube of the corollet. Receptacle rough with ſhort ſtiff projecting lanceolate points[p].

Native of moſt parts of Europe, in moiſt meadows, watery places, by the ſides of ditches, brooks and rivers; flowering from july to october, and frequently over-running large tracts of land, generally left untouched by all ſorts of cattle.

Ray obſerves, that the leaves when bruiſed ſmell like ſoap. Rutty informs us that the juice is ſaltiſh and warms the mouth a little, that the decoction is ſomewhat acrid in the throat, at the ſame time aſtringent and turning green with vitriol of iron; that the infuſion is ſomewhat aſtringent, very bitter in the throat, and turning black with vitriol of iron.

Linneus in his Flora Suecica mentions his having been informed by General Keit, that the Ruſſian ſoldiers, in their expedition againſt Perſia, were cured of the bloody flux by the uſe of this plant, whence Linneus gave it the name of *dyſenterica*[q]. It is called by our old authors Middle Fleabane, and was ſuppoſed by its ſmoke in burning to chaſe away fleas and other inſects. Forſkal ſays it is named in Arabic *Rara tjub* or Job's-tears, from a notion that Job uſed a decoction of this herb to cure his ulcers; and it was formerly recommended in the itch and other cutaneous diſorders.

7. This has been already deſcribed under Linneus's name of Erigeron viſcoſum. It is a native of the South of Europe, and was cultivated here in 1633, as appears from Johnſon's edition of Gerarde's Herbal[r].

8. Stem a foot high, round, upright, ſubtomentoſe: branches five, alternate, very ſtiff and ſtraight, rod-like, ſubdivided at the top. Leaves alternate, ſeſſile, embracing, with the lobes of the baſe adnate downwards, waved without any apparent ſerratures, hoary beneath. Peduncles terminating, one-flowered, with a few leaflets ſcattered on them. Calycine leaflets awl-ſhaped, curved in at the tip. Ray of the corolla ſhorter, with numerous, linear petals, three-toothed or five-toothed; diſk very convex. Flowers the ſame ſize with thoſe of Matricaria.—Native of Egypt[s]. Introduced in 1777 by Monſ. Thouin. It flowers in july[t].

9. This is an annual plant, reſembling the next ſort, but larger and ſtiffer. Leaves ſomewhat rugged, ſharp, naked above, ſubtomentoſe beneath. Peduncles many times as long as the flower, ſometimes having a ſingle leaf on them. Flowers like thoſe of I. Pulicaria, but with a longer ray, and the calyx leſs hirſute.—Native of the Eaſt Indies[u].

10. This is an annual plant, with a very trailing ſtem, not at all hairy, and a globular calyx. What has been taken for the Pulicaria of Linneus by botaniſts of England and other countries is different, and now therefore made a diſtinct ſpecies. See the next following.

The variety is larger and more rigid, but ſtill much ſmaller than ours[x].

Native of Scania, where water ſtagnates in winter, and even in the ſtreets of Lund[y].

11. Root annual, fibrous, whitiſh, jointed, generally crooked. Stem from a ſpan to a foot in height, upright not proſtrate, ſtriated, crooked, often tinged with purple, much branched; branches alternate, like the ſtem. Leaves alternate; lower ſeſſile, upper embracing, lanceolate, waved at the edges, ſlightly hairy and downy. Flowers terminating, numerous, broad, ſhort, cylindrical, on ſingle or branched leafy peduncles, the laſt blown ſtanding conſiderably above the others. Scales of the calyx numerous, awl-ſhaped, downy, the lower ones ſpreading. Florets of the ray very ſhort, three-toothed, often wanting. Briſtles on the anthers very minute and much ſhorter than the filaments. Seeds almoſt linear, brown, ſmooth; crowned with a ſeſſile egret of very few (about ſix, ſoon falling, *L.*) ſimple rays, ſhorter than the florets or ſeed[z].

Native of many parts of Europe, where water has ſtagnated during the winter, by road ſides, on the borders of ponds, &c. particularly in a ſtiffiſh ſoil. It flowers from auguſt to october.

Our plant always grows upright, and the upper part of the ſtem, the peduncles and leaves are woolly. The calyx is cylindrical, not globular[a]. Dr. Smith ſays that the ſtem is ſometimes decumbent, and that he can ſee no difference between our plant and Linneus's ſpecimen.

[a] Withering.

The

This alſo is ſaid to drive away fleas and gnats, and is given by ſome to horſes for the botts [b].

12. This reſembles *I. Pulicaria* ſo much, that it ſhould be diſtinguiſhed from it with caution. The leaves are ſubſpatolate, by no means embracing or waved. Calyxes cylindrical not globular, with approximating not ſquarroſe ſcales. Peduncles longer, often in pairs. Ray of the corolla longer, diſk narrower.—Native of the Eaſt Indies and Arabia [c].

13. The flowers of this are ſcarcely peduncled. It is a native of Italy [d].

14. Stem pubeſcent, ſtriated, often one-flowered. Leaves ſomewhat rugged, naked, ſubſerrate, more rugged about the edge. Flower large, terminating, ſeſſile. Calycine ſcales lanceolate, the outer larger [e].

It is thus deſcribed by Gouan.—Root perennial. Stems ſeveral, a foot or eighteen inches high, (Miller ſays two feet, which may be true of garden plants) angular, ſtriated, ſtiff, quite ſimple, rugged, tinged with red. Leaves rigid, ſcattered, hard, ſerrulate and rugged at the edge. Peduncles terminating, in corymbs, one-flowered or two-flowered. Leafy, rigid, ſwelling below the calyx. Calyxes very ſmooth, hard and ſquarroſe: ſcales ovate, ſhort, pauſious with the tip curved back, ſerrulate-ciliate, bluntiſh; the inner ſharpiſh. The flowers are pretty large, of a pale yellow colour, and appear in july, but are not followed by ſeeds in this country.

[In the autumn this plant puts on a different appearance: the ſtalk dies, and ſeveral young ones ſpring from the root, as in the ſeventh ſort, weak, red, clammy-haired; leaves fleſhy, ovate-lanceolate, clammy-pubeſcent, ſeſſile, with a ſmell like Elder. The ſtem and leaves retain their pubeſcence through the winter; but in the ſpring they become bald, the lower leaves periſh, and the ſtems are leafy only at top.

On account of this variety in the habit, it was long miſtaken for *I. ſalicina* [f]; which it reſembles indeed, but has a ſtem rather round though ſtriated, whereas in *I. ſalicina* it is angular: the leaves are ſmaller, firmer, ſhorter, with the end not ſharp, as in the other; the notches unequal and a little leſs: the calyx has five rows of ſcales in that, but it has only two or three at moſt in this, ending ſharply; in *I. ſalicina*, they are blunt, but awned: the radical flowers are narrower and longer alſo in that than in this [g].

Native of Italy and the South of France. Cultivated in 1768, by Mr. Miller [h].

15. This whole plant has ſome ſmell and a bitter unpleaſant taſte. Root perennial, conſiſting of numerous long and thick fibres. Stems ſeveral, upright, a foot and half high, roundiſh, leafy, ſometimes quite ſimple and terminated by a few peduncled flowers, ſometimes putting forth from ſeveral leaves ſimple axillary branchlets. Leaves acute, alternate, the uppermoſt quite entire. The ſtem branches and leaves have villoſe hairs more or leſs conſpicuous, but eſpecially along the edges and midrib of the leaves. Calyx ſmooth, ſcales ſubovate, the loweſt leafy, all except the inmoſt ſpreading ſquarroſely at the tip. Radial corollets ſharply and minutely three-toothed. Anthers briſtly. Seeds linear, brown, ſtriated, crowned with a hairy, ſeſſile down, appearing villoſe to the magnifier.

Native of Auſtria; flowering in auguſt and ſeptember [i].

16. Root perennial, aromatic, ſubaſtringent, ſmelling like cinnamon. Stem from a foot to two and even three feet in height, upright, ſmooth, hard, firm, tinged with red, grooved or angular towards the top, where it is uſually branched. Leaves alternate, ſeſſile or half-embracing, ſtiff, ſmooth, of a dark ſhining green, very ſlightly cut and ſomewhat rugged about the edge. Flowers terminating, on alternate, one-flowered, grooved, reddiſh peduncles, forming all together a corymb. Calycine ſcales in two rows, ſmooth, brown, lanceolate, curved back a little at the end. Flower an inch in diameter. Radial florets three-toothed. Down of the ſeed white ſeſſile [k].

It differs from the next ſpecies in having the ſtem ſmooth, grooved or angular at top; and the leaves ſmooth except that the edge is rugged [l].

Native of Germany, Switzerland, Auſtria, and the South of France.—Cultivated in 1683 by Mr. James Sutherland [m].

17. This has the habit of the preceding, but the leaves are broader, bluntet, ſcarce apparently ſerrate, veined, rugged eſpecially on the edge and along the keel, and rough on both ſides with a ſubruſous woolneſs. The ſtem has leaves and ſtiffiſh hairs ſcattered over it, and is entirely round, not grooved and angular. The calyx is alſo as it were leafy.

Linneus ſuſpects that Seguier's plant (*ver.* 2. 211.) referred to here under *I. ſquarroſa*, may be the ſame with this, on account of the ſimilitude in the calyxes [n].

Villars ſays, that none of Linneus's ſynonyms accord with this ſpecies, he thinks however that the *hirta* of that author is the ſame with his plant, becauſe they both reſemble *I. ſalicina*, and the leaves are rugged and almoſt entire. He thus deſcribes it.—Stem ſimple, round, ſlightly villoſe, a foot high, terminated by two or three flowers, each on a ſeparate peduncle. Leaves a little reſembling thoſe of *I. ſalicina*, but wider, whitiſh, villoſe and more rugged on the edge. Calycine ſcales a little villoſe, rugged, curved outwards, in about two rows. Ray of the flower ſhorter and narrower than *I. ſalicina*, and of a paler colour.

Pollich deſcribes the root as thick and fibrous. Stem upright, a foot or eighteen inches high, round, angular, ſubpubeſcent, branched. Leaves alternate, embracing, entire but commonly crenate, four inches long and half an inch wide, ſoft, pubeſcent, pale green, hanging down. Branches or peduncles three or four, ſhort, one-flowered, terminating. Calycine ſegments linear, narrow, turned back a little from the middle to the top, four lines long and a quarter of a line wide, pubeſcent and ſoft. Flowers handſome, an inch and half in diameter.

According to Krocker, it differs from the preceding, in having longer, broader, bluntet leaves, ſcarce apparently ſerrate, hirſute, rugged eſpecially at the edge and along the keel. Stem woolly round with ſtiffiſh leaves and hairs, and higher. Calycine ſcales wider, the outer ones leafy, lanceolate, green. It differs from *I. dyſenterica* in having a higher ſtem, the lower flowers ſtanding above the upper ones, the calycine ſcales as above deſcribed, and the whole habit leſs ornamental and leſs white.

Native of France, Germany, Switzerland, Auſtria, Siberia.—Cultivated in 1759. by Mr. Miller, and flowering here from june to ſeptember [o].

18. The whole plant has ſoft white hairs thinly ſcattered over it, eſpecially the lower ſurface of the leaves. The flowers terminate the ſtem in a ſort of corymb, but the peduncles or branches are commonly one-flowered, with pedicelled glands ſcattered over them [p].]

It riſes with a ſtrong ſtalk about a foot and half high, pretty cloſely ſet with prickly hairs. Leaves about three inches long, and near one inch broad in the middle. Towards the upper part of the ſtalk there are ſingle flowers coming out from the axils at each joint, and the ſtalk is terminated by a cluſter of ſmall yellow flowers. It flowers in auguſt, but has not perfected ſeeds in England.

Native of Maryland and Carolina. The ſeeds were ſent to Mr. Miller from South Carolina (in the Dictionary he ſays Maryland) in the year 1742, by his late friend Dr. Thomas Dale, which ſucceeded in the Cheſſea garden, where the plants flowered the following year; but the ſeaſon proving too cold to ripen the

[b] Krocker. [c] Linn. mant. [d] Linn. ſpec. [e] Linn. ſyſt. [f] Gouan illuſtr. [g] Allioni. [h] Hort. kew. [i] Jacquin. [k] Krocker, Pollich, Villars. [l] Linn. ſpec. [m] Hort. kew. [n] Linn. ſpec & ſyſt. [o] Hort. kew. [p] Linn. ſpec.

ſeeds, and the plants being biennial, they periſhed in winter.

19. This bears much reſemblance to *I. ſalicina*, particularly in the leaves, which however are ſhorter; the pedunces are more numerous and lengthened. The flowers are cylindrical, and cluſtered at the top of the ſtalk into a corymb. But the principal difference, according to Monſ. Villars, is in the calyx; which is almoſt oval, lengthened, and compoſed of three rows of ſcales curved outwards at their upper extremity [1].

Pollich diſcribes the ſtem as upright, a foot or eighteen inches high, round, pubeſcent, ſomewhat rugged, a little branched at top and curved towards the bottom. Leaves alternate, half embracing, ovate-lanceolate, ſharpiſh, quite entire, pubeſcent, rugged all over but eſpecially at the edge, veined. Flowers ſmall, terminating in a ſort of cloſe umbel. Calyx cylindrical, the lower ſcales lanceolate, ſpreading, the reſt turned back a little at the top only.

Native of the South of France, Germany, Auſtria, Siberia.]

Mr. Miller ſays it grows between three and four feet in height: that the leaves are turned backward, are indented on their edges, and rough on their upper ſide; that it flowers in june, and the ſeeds ripen in autumn.

[20. Stem herbaceous, round, ſtriated, villoſe, upright, a foot high and more. Leaves elliptic, with minute remote toothlets, villoſe, pale beneath, netted, the lower ones longer, two inches in length. Peduncles filiform, alternate from the upper part of the ſtem, upright, tomentoſe. Calyxes ovate, villoſe, linear-awl-ſhaped, patulous.

Native of Japan.

21. Stem herbaceous, ſimple, ſtriated, villoſe as is the whole plant, flexuoſe-erect, a foot high, leafleſs at top. Root-leaves ſeveral, ſubpetioled or attenuated into broad petioles: ſtem-leaves ſeſſile, alternate; all oblong, villoſe, ciliate; the upper ones ſmall. Flower terminating, ſolitary. Calyx very hirſute, equal [2].

Thunberg having only once had ſpecimens of this, and theſe not very good ones, the genus yet remains doubtful; but it ſeems to approach neareſt to the Inulas.

Native of Japan.

22. Root perennial. Stems annual, from ſix inches to a foot in height, ſome one-flowered, others branched and few-flowered from the upper axils, almoſt ſmooth, when cultivated ſomewhat lanuginoſe at bottom. Leaves enſiform, ſometimes approaching to narrow-lanceolate, rigid, flat, ſhining, very finely ſerrulate. The flowers have a little ſmell. Scales of the calyx ſomewhat villoſe, ending in a narrow-lanceolate ſharp and very ſpreading leaflet, which is longer in the outer ones; the inmoſt ſcales have it not, and are pale green with brown tips and upright. Radial florets three-toothed. Anthers two-briſtled. Seeds brown, with a down five times its length, toothletted with the magnifier.

Native of Auſtria, on rocks among buſhes, flowering in auguſt [3].

23. Root perennial. Stems firm, ſmooth, ſtriated, much branched; branches cloathed with linear leaves, either three-toothed or entire at the extremity; they are crowded at the ends of the branches. (According to Withering, the lower leaves have teeth at the end, and ſometimes a few at the ſides; the upper ones are entire.) Flowers ſolitary, on thick peduncles, at the ſummit of the upper branches. Calycine ſcales numerous, yellow-greeniſh, fleſhy, awl-ſhaped. Seeds villoſe, crowned with the ſeſſile egret ſhorter than the florets, compoſed of few rays, when viewed with a glaſs finely toothed on one ſide [4].

Native of England, France, Spain, Portugal, the coaſts of the Mediterranean Sea, Barbary, &c. and Arabia; in ſalt-marſhes, in a muddy ſoil.] Mr. Miller ſays, he has obſerved it plentifully near Sheerneſs, in the iſle of Shepey, in Kent: [where Gerarde, Ray and others had ſeen it before. Ray remarked it in a marſh near Hurſt-Caſtle over againſt the Iſle of Wight, and on the rocks at Llandwyn in Angleſea. Mr. Newton found it on the bank of the river juſt above Fulbridge at Malden in Eſſex; Mr. Baker in Portland iſland.]

According to Mr. Miller, it riſes with an upright ſtalk a foot and half high. Leaves ſucculent, fleſhy, an inch and quarter long and one eight of an inch broad, ending in three points, and coming out in cluſters. It flowers in july, and the ſeeds ripen in autumn.

The younger branches are frequently ſold in the London markets for Sampire; but this is a great abuſe, becauſe this plant has none of the warm aromatic taſte of true Sampire (Crithmum maritimum.)

Vahl affirms, that the Senecio ſucculentus of Forſkahl agrees in all reſpects with the ſpecimens of Inula crithmoides collected on the coaſts of the Mediterranean, and that in Barbary the ſtems are conſtantly perennial. He deſcribes the ſtem as ſhrubby (fruticuloſus), round, procumbent at the baſe, branched at bottom; the branches ſcattered and ſpreading. Leaves ſmooth, broader towards the top, the upper ones quite entire, the lower with a tooth on each ſide at the tip. Peduncle at the end of the branches, one-flowered, elongated, with minute linear ſcattered ſcales. Anthers two-briſtled. Egret ferruginous-purpliſh.

24. This plant has ſtrong fibres to the root. Stem a foot high, quite ſimple, villoſe. Root-leaves bluntly ſerrate, villoſe underneath, blunriſh; ſtem-leaves few, lanceolate, ſeſſile, leſs ſerrate, villoſe underneath; the upper ones linear. Flowers rather large [5].

According to Gouan it is not unlike Senecio incanus, being hoary all over. Root-leaves petioled, from half an inch to an inch in length, blunt, ovate, quite entire; others crenate, and others again pinnatifid, with three or four pinnules on each ſide. Stem an inch, two inches, or a hand high. Stem-leaves alternate, one to four, linear, hoary quite entire or pinnatifid. Flower large. Calyx tomentoſe-hoary. Peduncle ſwelling below the flower.

Haller ſays it is a handſome plant, with a woody root having abundance of fine fibres. Root-leaves thick, ſolid, white-tomentoſe on both ſides, ſome ovate, round, toothed, others twice, thrice or four times gaſhed, or pinnatifid; the pinnules roundiſh. Stem-leaves pinnatifid and ſimple. Stem not branched, naked, half a foot high, one-flowered. Flower an inch in diameter, ſpreading. Calyx tomentoſe, leaflets ſtraight, lanceolate, in three rows. Radial florets about fourteen, three-toothed.

Haller refers the ſynonym of Bauhin, here given, to Senecio Doronicum.

Native of the South of France, where it was found about Narbonne by Pech on the Corbieres a part of the Pyrenees. Alſo in the Upper Valais, and in the mountains of Piedmont by Allione.—It was introduced here in 1778, by Monſ. Thouin, and flowers in july and auguſt [6].

25. Root hard, fibrous. Stem a long ſpan or a foot high, round, firm, upright. Leaves thickiſh, green above, ſubhirſute and wrinkled, beneath ſilky-tomentoſe, root leaves petioled, elliptic, ſtem-leaves few, lanceolate, acute. Flower large. Calycine ſcales broad, tomentoſe, lanceolate, with the tips bent back. Florets of the diſk very numerous, of the ray as far as thirty, broad, three-toothed [7].

The ſtem is a foot or eighteen inches in height, according to Pollich, hairy, rugged, grooved or ſubangular, commonly not branched, but the branches, when there are any, alternate. Leaves alternate, ſeſſile from upright ſpreading, ſubobliique, blunriſh, pale green, rugged. Flower ſubſeſſile, handſome, an inch and more in diameter. Calycine leaflets looſe, lanceolate, ciliate, hairy, rugged, from upright ſpreading.

Villars ſays, it is lower than the preceding ſorts. The ſtem half a foot long, inclined at the baſe. Lower leaves oblong, blunt, ruſſet, villoſe; ſtem-leaves linear.

It varies with ſubſerrate leaves, and ſmall flowers: and when cultivated long in a garden, the leaves become wide, like thoſe of Verbaſcum, and the ſtem higher, ſtraighter, terminated by four or five flowers.

[1] Linn. ſpec. & Villars dauph. [2] Thunberg. [3] Jacquin. [4] Woodw. Mſs. [5] Linn. ſpec. [6] Hort. kew. [7] Haller.

Allione

Alilone remarks, that the leaves are not quite entire, but somewhat toothletted; and that the ſtem is not always one-flowered, but has ſometimes two and three flowers.

Linneus obſerves, that the calyx and ſtructure of the plant makes it very nearly allied to the After; and that it is covered with a ſnowy white pubeſcence.

Native of Spain and the country about Montpellier and Vienne. In all the ſouthern part of Dauphiné. Near Turin, and in other parts of the King of Sardinia's dominions. In the vineyards of the Palatinate. In Switzerland and the Valais.—Cultivated in 1759, by Mr. Miller. It flowers in july and auguſt [a] but rarely ripens ſeeds here.

[26. Native of South America.

27. Stem a foot high, ſomewhat rigid, corymbed, with a ſtrong ſmell like Tanſy. Flowers yellow, with a ſhort ray. Biennial. Compare *Conyza bifrons*, which botaniſts determine to be the ſame plant without any ray to the flower [b].]

Mr. Miller deſcribes it as a foot high, dividing into many branches. Leaves oval, hairy, half-embracing. Each branch is terminated by one large yellow flower, with the ſcales of the calyx oval. It flowers in july and auguſt, but never perfects ſeeds in this country.

[Native of Italy Provence, and the Pyrenees. Cultivated by Mr. Miller in 1768.

28. Though this has a blue ray to the flower, in which it differs from all the Inulas, yet its appearance or habit is quite foreign to that of the Afters. The branches are one-flowered. The anthers are tailed, as in moſt of the Inulas. The receptacle is honeycombed [b].

Native of the Cape of Good Hope.

29. Branches alternate, crowded, ſimple. Leaves alternate, crowded, curved back at the edge. Flowers ſolitary, terminating, ſeſſile. Calyxes oblong, imbricated. Ray of the flower pale whitiſh fleſh-colour.

30. This is a rugged ſhrub, having the appearance of a Larch, with rod-like branches. Leaves mucronate, ſmooth. Flowers ſubſolitary, ſeſſile, terminating. Egret ſimple [c].

Stem half a foot high, very rugged with the fallen leaves, like the Fir, with the branches in whorls. Leaves ſcattered, green. Scales of the calyx linear [c].—Both natives of the Cape.

31. This is allied to *Senecio foetidus*, with the habit of *Cineraria* [a]. In Linneus's ſpecies it is ſaid very much to reſemble *Erigeron foetidum*, except that it has radiate flowers. In the Mantiſſa it is ſaid to bear a great affinity to the genus *Cynara*.

Boccone, who firſt diſcovered this plant among the rocks of the iſland of Malta, thus deſcribes it.—Stems ſeveral, a foot high, ſtraight, branched, rough with harſh hairs. Leaves alſo hirſute, alternate, oblong, undivided, not unlike thoſe of Hyſſop or the Olive, blunt at the end. Flowers golden-coloured.]

32. This riſes with ſeveral ſhrubby ſtalks near four feet high, which divide into ſmaller branches. Leaves in cluſters, narrow, fleſhy, divided into three ſegments at their points. The flowers come out on the ſide of the branches at the top of the ſtalks; they are ſmall, and of a pale yellow colour, appearing in auguſt.

Native of the Canary iſlands. Cultivated by Mr. Miller.

33. This riſes with a ſhrubby ſtalk about two feet high, dividing into many ſmaller branches, which are hairy. Leaves narrow, ſtiff, ſeſſile; from the edges of theſe ariſe long hairs, which are ſtiff, and come out by pairs; at the end of the branches ariſe naked peduncles, four or five inches long, ſuſtaining one ſmall, yellow, radiated flower. It was diſcovered by Dr. Houſtoun at La Vera Cruz; and was cultivated by Mr. Miller before 1733.

34. Stem ten or twelve feet high, divided into ſeveral woody branches. Leaves five inches long, and one inch and a half broad in the middle, ſmooth on the upper ſide, but on their under having three longitudinal veins. The flowers are produced at the end of the branches, having very large ſcaly calyxes; they are as large as a ſmall Sun flower, of a pale yellow colour. It was firſt diſcovered by Dr. Houſtoun at Carthagena in New Spain; and was cultivated by Mr. Miller before 1733.

[a] Hort. kew. [b] Linn. ſpec. [c] Berg. & Linn. ſyſt. [d] Linn. amoen. [e] Linn. mant. [f] Linn. ſyſt.

PROPAGATION AND CULTURE.

1. Common Elecampane may be propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe; for if they are kept till the ſpring, they ſeldom grow; but where they are permitted to ſcatter, the plants will come up the following ſpring without any care, and may be either tranſplanted the following autumn; or if they are deſigned to remain, they ſhould be hoed out to the diſtance of ten inches, or a foot each way, and conſtantly kept clean from weeds; theſe roots will be fit for uſe the ſecond year.

But moſt people propagate the plants by offſets, which, if carefully taken from the old roots, with a bud, or eye, to each, will take root very eaſily; the beſt time for this is the autumn, as ſoon as the leaves begin to decay; theſe ſhould be planted in rows about a foot aſunder, and nine or ten inches diſtance in the rows; the ſpring following the ground muſt be kept clean from weeds, and if in autumn it is ſlightly dug, it will promote the growth of the roots; theſe will be fit for uſe after two years growth, but the roots will abide many years, if they are permitted to ſtand; however, the young roots are preferable to thoſe which are old and ſtringy. It loves a gentle loamy ſoil, not too dry.

2 to 5. 16, 17, 18, 19. 22. 24. 25. are abiding plants, which will thrive and flower in the open air in England; they may be all propagated by parting of their roots. The beſt time for doing of this is in autumn, at which time the plants may be removed; theſe may be intermixed with other flowering plants in the borders of large gardens, where they will make an agreeable variety during their continuance in flower. As theſe roots multiply pretty faſt, they ſhould be allowed room to ſpread, therefore ſhould not be planted nearer than two feet from other plants; and if they are removed every third year, it will be often enough, provided the ground between them is dug every winter, and, in ſummer, if they are kept clean from weeds, they will require no other care.

As ſome of theſe ſorts produce good ſeeds in England, they may be propagated by ſowing of the ſeeds in the autumn, on a border of light earth expoſed to the eaſt, where the morning ſun only is admitted; and in the ſpring, when the plants appear, they ſhould be kept clean from weeds till they are fit to remove, when they ſhould be tranſplanted on a ſhady border, ſix inches aſunder, obſerving to ſhade and water them till they have taken new root: and during the ſummer ſeaſon they ſhould be kept clean from weeds, and in autumn they may be tranſplanted into the borders where they are to remain.

[6. 10, 11. 23. Being natives of Europe, and common, are not cultivated in gardens.

7. See Erigeron viſcoſum.

8, 9, 12. Being annual plants, and natives of hot countries, muſt be propagated by ſeeds raiſed in a hot-bed, and kept in the bark-ſtove.]

13, 14, 15. 27. are propagated by ſeeds, which ſhould be ſown on a bed of light earth early in the ſpring; in may the plants will appear, which ſhould be kept clean from weeds till they are fit to tranſplant, when they ſhould be planted in an eaſt border, at about ſix inches diſtance each way, watering and ſhading them till they have taken new root; after which they will require no other culture but to keep them clean from weeds till the autumn, when they ſhould be planted where they are deſigned to remain.

The fourteenth ſeldom continues above two or three years, and therefore young plants ſhould be conſtantly raiſed from ſeed to ſucceed the old ones.

[28. 29, 30. Being ſhrubby Cape plants, may be increaſed by cuttings, and muſt be preſerved in the dry ſtove.]

32. The thirty-ſecond ſort will not live abroad in the open air in England, during the winter ſeaſon, ſo muſt be removed into ſhelter in autumn, but ſhould have

as much free air as poſſible at all times, when the weather is mild, otherwiſe it is apt to draw up weak. In cold weather the plants muſt have very little water, for their ſtalks and leaves being ſucculent, they are very apt to rot with too much wet; in ſummer they ſhould be placed abroad with other hardy exotic plants in a ſheltered ſituation, where they will add to the variety, though they are plants of no great beauty, and ſeldom flower in England, unleſs the ſummer is very warm. This is eaſily propagated by cuttings, any time in ſummer, which, if planted in a ſhady border, will take root in a ſhort time.

33. This is propagated by cuttings during the ſummer ſeaſon, which muſt be planted on a bed of light earth, and ſhaded till they have taken root; after which the plants muſt be treated in the ſame manner as other hardy exotics, ſheltering them from froſt in winter.

34. This being too tender to live in the open air in England, muſt be conſtantly kept in the bark ſtove. It is propagated by ſeeds which muſt be procured from the country where it naturally grows, for it does not produce any here; theſe muſt be ſown upon a hot-bed, and when the plants are fit to remove, they ſhould be each put into a ſmall pot filled with light earth, and plunged into a freſh hot-bed; treating them in the ſame manner as other tender plants from the ſame country.

DESCRIPTIONS, *&c.*

This is a very large tree, with a trunk forty or fifty feet high, and two or three feet in diameter, with a ſmooth ruſſet bark, and a white uncompact wood. It has a great number of branching boughs at top, thoſe in the middle erect, the reſt horizontal and ſpreading in all directions. Leaves alternate, unequally pinnate; leaflets in three, four or five pairs, almoſt but not quite oppoſite, ſmooth, thin, entire, oval, acuminate; the largeſt ſix inches in length, and two inches and a half in width, the lower ones of each leaf ſmaller. Petiole almoſt cylindric, eight or nine inches long, thick and fleſhy at the baſe. Flowers ſmall, numerous, white, axillary and terminating, in large wide ſcattered panicles.

Native of Guiana, where it is called Tapiriri. It flowers in november, and bears fruit in april *.

Floral leaflets under each calyx one, lanceolate ſeſſile, permanent, three times as long as the calyx.]

DESCRIPTIONS, &c.

1. This is an annual plant, riſing with two oblong pretty broad ſeed-leaves, which remain a conſiderable time before they fall off. Stems ſlender, twining, and riſing by ſupport to the height of ſeven or eight feet; ſending out ſeveral ſide-branches, which twine about each other and the principal ſtem, and about any neighbouring plants. The leaves are compoſed of ſeveral pairs of very fine narrow lobes, not thicker than fine ſowing thread, about an inch long, of a deep green, either oppoſite or alternate. The flowers come out ſingly from the ſide of the ſtalks, on ſlender peduncles about an inch long. The tube of the corolla is about the ſame length, narrow at bottom, but gradually widening to the top; where it ſpreads open flat, with five angles; it is of a moſt beautiful ſcarlet colour, and makes a fine appearance.

[Loureiro affirms that the capſule is uſually four-celled, which perhaps may be owing to his having ſeen it only in a ſtate of luxuriance from cultivation; for he does not ſay that he obſerved it wild in China and Cochinchina.

Browne ſays it is cultivated in many of the gardens of Jamaica, on account of its beautiful flowers, and minutely diſſected thick foliage, that it is a weakly climber, and ſeldom riſes above four feet from the ground. He gives it the name of *American Jaſmine.*] Mr. Miller ſays it is called in the Weſt Indies *Sweet William*, and by ſome *Indian Pink*. The flowers appear in july and auguſt, and continue in ſucceſſion great part of ſeptember. He ſays it grows naturally in both Indies, and that in the Weſt India iſlands it runs up the hedges to a conſiderable height. [It is certainly a native of the Eaſt Indies, whence it was probably tranſported to the Weſt Indies, of which it does not ſeem to be aboriginal.

Cæſalpinus firſt (1580) gave a ſhort deſcription of this plant, as then newly arrived from India, under the name of *Geſſeminum rubrum alterum*; next to him, Camerarius gave a figure and deſcription of it, by the name of *Quamoclit*; and Columna, following Camerarius, deſcribed and figured it more accurately[1].—Our old authors regarded it as a native of America, and Parkinſon calls it, *The red Bell-flower of America.* He ſays, (1629) "it is a rare plant, that we ſeldom "have, and can hardly keep, that it periſhes every "year, and with us will ſeldom come to flower, be-"cauſe our cold nights and froſts come ſo ſoon, before "it can have comfort enough of the ſun to ripen it." Johnſon, in the appendix of his edition of Gerarde's Hiſtorie of Plants calls it *Winged Bindt-weed*, and gives a figure from Cluſius's curæ poſteriores, with a deſcription borrowed from Columna. He ſays, "it is ſo tender "a plant, that it will not come to any perfection with

[1] Ray hiſt. and Ger. emac.

" us, unleſs in extraordinary hot years, and by artifi-
" cial helps. By reaſon of the great plenty of leaves
" and flowering ſtalks or branches winding themſelves
" about artificial hoops, croſſings, or other faſhioned
" works of reeds, or the like, ſet for winding herbs
" to climb upon, it much delights the eye of the be-
" holder, and is therefore kept in pots, in gardens of
" pleaſure."

2. The young plants, the firſt year, produce numerous leaves, ſpreading in a circle, elegantly jagged, ſomewhat like the finer ones of Coronopus, or Buck's-horn Plaintain; from the centre of theſe, the ſecond year, ariſes a ſtraight ſtem, ſimple or unbranched below, but having ſeveral branchlets on the upper part; it is the thickneſs of a wheat ſtraw at bottom, and three quarters of a yard or more in height; it is clothed from top to bottom with leaves, reſembling thoſe of Hottonia, and placed alternately; the lower ones broader, longer, and divided into more ſegments; which are fewer and more finely cut the nearer they are to the top. Flowers from the top of the ſtem, and the ends of the ſide branchlets, peduncled, pendulous, uſually ſolitary, but forming all together a thyrſe. (raceme; *Lin.*) Corolla of a bright red colour, darker on the outſide; within paler, and variegated with white ſpots and purple ſtreaks. When the ſtem puſhes up, the root-leaves wither away; and the ſtem itſelf, though rigid, ſoon periſhes after flowering [a].

According to Linneus, who had it from Ellis, it is of a doubtful genus. He firſt ranged it with the Polemoniums, though he allowed the appearance to be different. The ſtem is ſuffruticoſe and ſtraight; the plant is not milky; the calyx is one-leafed, with a ſhort tube, and awl-ſhaped teeth longer than the tube. Stamens inſerted into the middle of the tube of the corolla without valves [b].

Native of Carolina, two hundred and fifty miles above Charles Town, in low ſandy places, where it was found by Cateſby flowering in june. He ſent the ſeeds to Dr. James Sherard, and it was cultivated in the Eltham garden before 1732. It flowered there in october, but the plant periſhed [c].

3. Leaves petioled. Leaflets ſeven, lanceolate, quite entire, acuminate, ſeſſile, almoſt equal. Peduncles axillary: flowers very abundant. Capſules oblong, three-cornered, acuminate, ſmooth [d]. Native of South America.

4. Stem ſlender, trailing. Leaflets ſeven, oblong, broad at the end, and blunt. Outſide of the corolla light green, inſide purple; border ſix-cleft, with the verges bent back. On many of the Bahama iſlands, on rocks [e]. Found there by Mr. Cateſby.

5. Stem herbaceous, twining, quadrangular, ſmooth, flexuoſe. Leaves petioled, pentangular, ſmooth on both ſides. Peduncles very long, axillary, upright, round, two-parted-bifid, on one-flowered pedicels. Flowers long, ſcarlet, larger than thoſe of the firſt ſort. Calyx five-cleft, with lanceolate ſegments. Tube of the corolla narrower at the baſe, long, columnar, curved a little and ſhining: border plaited, blunt; baſe nectareous. Stamens longer than the corolla: anthers whitiſh. Germ ſuperior: ſtigma marked with four lines. Capſule four-celled, four-ſeeded. Seeds ſolitary, roundiſh-angular, wrinkled, black [f].

It is an annual plant, ſix or eight feet high. The corolla is not ſo deep-coloured as that of the firſt ſort; and there is a variety with orange-coloured flowers.

[Browne obſerves, that it is remarkable for the curved or arched figure of the tube in the corolla.

Native of the Weſt Indies. Cultivated in 1759 by Mr. Miller. It flowers from june to ſeptember [g].

6. Stems from a foot to two feet in height, ſlightly angular, procumbent unleſs ſupported, and then climbing. Leaves having little pits on the ſurface, (whence Linneus's trivial name), on petioles from half an inch to an inch in length; from the axils of theſe, on ſhort peduncles, ſpring the flowers, uſually ſolitary, but ſometimes two on a peduncle, ſmall, white, with the edges ſlightly tinged with purple, and the ſegments ſharp-pointed; the tube is ſhorter than in I. Quamoclit, the ſtamens ſtand out leſs, and are cloſer together. The ſeed-veſſel ordinarily contains in two cells four ſeeds, which are convex on one ſide, and flat on the other; it is ſlightly hairy towards the top, but all the other parts of the plant are free from hairs. The ſeed-leaves are two-lobed, and reſemble the ſeed of the Acer or Maple in form [h].

Linneus ſays that it bears a great reſemblance to I. coccinea, but that the peduncles are one-flowered, or at moſt two-flowered; the tube of the corolla thicker, and the corolla itſelf of a different colour [i].

It is an annual plant, and a native of Virginia and Carolina, whence the ſeeds were ſent to the Eltham garden [k], and there it was cultivated before 1732: but we had it ſooner than this, according to Parkinſon's Theatre of Plants, publiſhed in 1640. It flowers here in july [l].]

7. This reſembles I. coccinea, but the leaves have no angles, and the flowers are of a roſe-colour. [Native of America. Cultivated by Mr. Miller in 1759.

8. Root tuberous. Stems ſeveral, ſhrubby, twining, woody at bottom, and the thickneſs of the human thumb. Leaves ſmooth, on long petioles the ſize of a man's hand. Pedimcles many-flowered, axillary. Flowers yellow, (bright yellow, *Miller.* ſulphur-coloured, *Linn.* purple, *Lour.*) handſome, two inches in diameter, ſmelling ſweet. Capſule membranaceous, ſhining, ſubpellucid, ſquare with blunted angles, large, two-celled; in each cell two black, villoſe ſeeds, among the largeſt of the genus.

The plant is wonderfully beautiful when in flower, and the very fragrant odour of the flowers gives it an additional value [m]. It is much uſed in the Weſt Indies for arbours, for which it is very fit, on account of the multitude of its branches and ever-green leaves, which the ſun cannot penetrate. It ſpreads to ſuch an extent, that it may be carried over an arbour of three hundred feet in length, from one root [n]. Every part of the plant is purgative, and abounds with milk; probably Scammony might be made from the milky juice of the root [o]. Loureiro affirms that the tubers are eatable, like Batatas, (Convolvulus) which they reſemble very much in taſte, ſize and ſhape.

Native of the Weſt Indies, where, however, Jacquin informs us that he found it wild only in St. Domingo, on the higher mountains near Cape Francois. Browne thinks that it was introduced into Jamaica from the Continent. It is called in that iſland *Seven-year Vine* or *Spaniſh Arbour-Vine*. If I. tuberoſa of Loureiro be the ſame with this, which ſeems doubtful, from his account of the colour of the flower and quality of the root [p]; it is found alſo in Cochinchina, but originally from Siam.]

9. This has a ſmooth twining ſtalk, which riſes four or five feet high. Leaves ſeſſile, five-lobed. The flowers come out from the ſide of the ſtalk upon ſhort peduncles, which ſuſtain two or three purple flowers. Seeds brown. Native of the Weſt Indies. [Cultivated by Mr. Miller in 1759.

10. This is an annual plant, growing to a very great length, covering ſometimes many trees, or the banks of rivers for many paces, having a round and reddiſh ſtalk, armed with blunt, herbaceous, ſhort variouſly ſhaped prickles, winding itſelf about any thing it comes near, or creeping along the ſurface of the ground. At unequal diſtances come out on petioles ſix inches long, ſmooth petioled leaves, four inches long, and as broad from ear to ear at the baſe, there being a ſinus or hollow from the ears to the point. The flowers are axillary, many, on peduncles an inch long; the tube of the corolla is ſeldom leſs than from three to four inches in length; the border is white, five inches in diameter, a little ſinuated, and has five green ſtreaks on the outſide [q].

Browne obſerves that the leaves of this plant, and indeed of all the ſpecies both of Convolvulus and

Ipomoea, are very variable, being ſometimes in the form of a heart, and ſometimes lobed, or panduriform: ſometimes alſo the ſtem only is prickly, ſometimes both ſtem and petioles.

Gærtner deſcribes the fruit not as a capſule, but as a juiceleſs berry, globular, one-celled, ruſeſcent or black, ſmooth: rind leathery, when ripe ſeparating from the pulp, within covered by a very fine white membrane, and marked with ſix longitudinal ſtreaks: pulp fungoſe, ſnowy-white, thin, perforated by filiform nutritious veſſels, ſo cloſely adhering to the ſeeds, that it may be ſeparated along with them into four parts. Receptacle none, except the conical riſing at the bottom of the berry, to which the ſeeds and nutritive veſſels of the pulp are fixed. Seeds four, ovate, on one ſide convex with a groove, on the other angular, perforated near the baſe with a large umbilical aperture; they are ſmooth, and of a pale teſtaceous colour.

He refers the other ſpecies of Ipomoea (except his zeylanica) to the genus Convolvulus, becauſe they have a genuine capſule, ſeparable into valves.

Native of the Weſt Indies. Introduced in 1773, by John, Earl of Bute. It flowers here in july and auguſt[s].

11. Corolla thicker than in the reſt. Under the five-parted perianth there is another ſmaller orbicular perianth, which is quite entire. Native of the Eaſt Indies[t].

12. The round green ſarments or ſtalks of this plant mount about any tree, ſhrub or hedge, to a great height, (ten or twelve feet, *Miller*.) cloathing them green, with their many branches and leaves; theſe are two inches and a half long, and two inches broad at the round baſe from one ear to the other, ſmooth, yellowiſh green, on petioles an inch and quarter in length. Flowers pale purple, (blue, with their brims not angular, but entire, *Miller*.) very large, bell-ſhaped. Capſule brown, having above five valves, four round protuberances, and in each of them a large triangular ſmooth ſolid whitiſh brown ſeed[u]. Theſe diviſions of the capſule are probably not natural, but the effect of luxuriance. Native of the Weſt Indies. Cultivated by Mr. Miller in 1759.

13. Stem ſeeming to be decumbent, flexuoſe, half a foot high, branched at the baſe, having hairs ſcattered over it, few in number below, but more abundant above. Leaves petioled, an inch long, bluntiſh, with a ſhort dagger point, veined, with a few hairs on the veins underneath, when more advanced ſmoother. Lower petioles twice as long as the leaves, and ſmooth; the upper ones hairy. Peduncles from all the axils from top to bottom, angular, thickening upwards, one-flowered; having a few ſhort linear bractes at the baſe. Leaflets of the calyx ovate, acute, when young covered with long hairs, but when farther advanced ſmoother and ciliate. Capſule the ſize of a pea, and ſmooth. Seeds tomentoſe, and ſomewhat ſilky[x].

14. Stem ſhrubby, in open places almoſt upright, and ſupporting itſelf to the height of a man, but in woods climbing twenty feet high; the whole plant, except the ſeeds, very ſmooth. Bark aſh-coloured. The younger green branches are adorned with leaves, which are roundiſh-cordate, acuminate or blunt, with a ſmall point, quite entire, veined, alternate, ſometimes eight inches in length and breadth, on petioles three inches long. Peduncles ſubracemed and terminating. Flowers elegant, but void of ſmell, three inches in diameter, fleſh-coloured, opening in ſucceſſion. Capſules brown and ſhining, containing blackiſh ſeeds wrapped up in abundance of brown-aſh-coloured wool.

This plant having many things in common with Convolvulus, might not unaptly be referred to that genus; but in truth there are no conſtant limits between them.

Found by Jacquin every where about Carthagena in America, in ſandy coppices near the coaſt; flowering in february and march. It grew from ſeed to a conſiderable height in the ſtove of the Imperial garden at Vienna, but periſhed without bearing ſeed.

[s] Hort. kew. [t] Linn. ſpec. [u] Sloane. [x] Vahl.

15. The plant is very ſmooth all over, and perhaps annual. Stems round, twining. Leaves bluntly acuminate, with a ſmall point, green above, but glaucous with violet-coloured veins on the back, petioled. Common peduncles ſolitary, axillary, thick, almoſt the length of the leaves: partial commonly trichotomous: proper frequently falling along with the flowers; which are elegant, very ſhining, ſcarlet, inodorous, numerous, two inches in diameter, but the ſegments being plaited on the ſides appear at firſt ſight much narrower and lanceolate. Native of Martinico, in coppices on the hills near the town of St. François; flowering in december and january[y].

16. The whole plant is very ſmooth, with round twining ſtems climbing up ſhrubs to the height of ten feet. Leaves extremely blunt, with a ſtipular point, varying much in ſize, and on ſhort petioles. Racemes axillary, very looſe, ſlender and longer than the leaves, ſpreading out ſtiffly. Flowers purple, inodorous, very numerous. Capſules brown, incloſing ſmooth black ſeeds. Native of woods in Martinico, eſpecially on the borders of the ſalt marſhes; flowering from november to january[z].

17. Leaves cordate-haſtate, with two ears on each ſide, on a plant that did not flower. Flowers yellow, according to Burmann[a]. Native of Java.

18. This plant is wholly ſmooth. Stem twining, angular, with decurrent lines. Leaves petioled, an inch and half long and more, five-nerved; lobes attenuated, blunt, mucronate; the middle one lanceolate-oblong; the ſide ones lanceolate, divaricate, broader on the outer ſide, produced at the baſe into an angle, which is commonly ſublobed. Peduncles longer than the leaf, pedicels lateral, two or three-flowered. Calyx ſmooth; leaflets oblong, acuminate, with an awn the length of the leaflet. Corolla of the ſame ſize and form with I. coccinea. Obſerved in the iſland of Santa Cruz by Weſt[b].

19. Root perennial. The whole plant is ſomewhat glaucous and ſmooth. It grows half a yard and upwards in height, with a ſlender twining ſtem. The firſt leaves are oblong-cordate and ſcarcely angular, like thoſe of the ſmaller field Convolvulus, next they become more angular, and finally larger, more concave, and ſtill more angular, ſagittate and even haſtate, ſometimes cut off in a ſtraight line, or truncate at the baſe, but generally irregular at leaſt on one ſide; reſembling thoſe of the great wild Convolvulus or Bindweed. Peduncles axillary, ſolitary, ſlender, from an inch and half to two inches in length, (on older plants ſhorter) uſually two-flowered, but ſometimes one-flowered only. Flowers ſmall, fleſh-coloured or very pale purple, of the figure and ſize of Venus's Looking-glaſs (Convolvulus Speculum); with a ſhort tube concealed within the calyx, and ſhort ſpreading ſegments: they do not expand here till about noon; but appear the greateſt part of the ſummer. Capſules three-celled or four-celled, with one ſeed in each cell. Native of Mexico[c]. Cultivated in the Eltham garden about 1732; but ſince loſt to the European ſtoves.

20. Root annual. Stem twining, angular, ten or twelve feet high. [Leaves three-lobed, or rather deeply trifid; the ſegments quite entire, ſmooth, and almoſt equal; the middle one ovate, the ſide ones ſemicordate. Corollas cylindric, violet-coloured. Stigmas two, globular. Capſules hairy[d].

It is allied to Convolvulus edulis; but that has the firſt leaves undivided, the next trifid, than quinquifid, and ſometimes even ſeptemfid or ſeven-cleft, but with the ſide-lobes very ſmall. It varies with one, two and three flowers on a peduncle; with violet, red and white corollas, and with black and white tubers to the root[e].

Native of the Weſt Indies and Japan; where it flowers from auguſt to october. Here it flowers in june and july. Cultivated by Mr. Miller in 1759[f].

21. Stem twining, ſmooth, triangular with decurrent lines, even. Leaves an inch and half in length, ſmooth,

[y] Jacquin. [z] Ibid. [a] Linn. mant.
[b] Vahl. [c] Dillenius. [d] Linn. ſpec. and Thunb.
[e] Thunberg. [f] Hort. kew.

pater

palet beneath: lobes lanceolate, blunt, mucronate; the ſide ones ſhorter, the outmoſt gibboſe at the baſe on the outſide, the two middle ones narrower. Petioles filiform, longer than the leaf. Peduncles three times as thick as the petiole, longer than the leaf, triangular: pedicels in threes or ſixes, angular, muricated, one-flowered, jointed at the baſe. Calycine leaflets ovate, mucronate, the length of the capſule. Corolla ſmall.—It is allied to I. triloba, but ſeems to differ in having a ſmooth even ſtem, whereas in that it is hirſute and rugged; five-lobed leaves, and peduncles commonly ſix-flowered[x].

According to Sloane, it has a ſmall ſtringy root, a round purple ſtalk, two feet high, purpliſh green leaves, divided almoſt to the petiole, and ſomewhat like thoſe of the Papaw; the flowers are purple.

Native of Jamaica and Santa Cruz.

22. The corolla in this is four times as long as in I. triloba, and the peduncles bear many flowers in racemes[y].

It is an annual plant, a native of South America, and was introduced here in 1773, by Joſeph Nicholas de Jacquin, M. D.[z]

23. This riſes with a twining hairy ſtalk four or five feet high. Leaves palmate, five-lobed, ſeſſile. Flowers axillary, on ſhort peduncles, two or three together, purple. Capſules round, three-celled, with one brown ſeed in each cell.

[Stem annual, ſimple, ſlender. Leaves cordate, three-lobed, ſomewhat ſharp, hairy, on long petioles. Flowers axillary, blue, on one-flowered, heaped peduncles, not properly aggregate. Tube of the corolla long, thickiſh, border five-cleft. Capſule three-celled[a].

Native of Ceylon and Cochinchina. Cultivated by Mr. Miller in 1759.

24. Flowers cloſely heaped together in heads, and ſurrounded with many hairy leaves. Capſules depreſſed, rounded-four-cornered, two-celled, containing two ſeeds in each cell: but the principal diſtinction conſiſts in the leafy heads and aggregate flowers. Calyxes divided to the bottom into five narrow hairy ſegments, and on the peduncles one or two oblong narrow hairy leaves, ſo that the whole head has a hirſute appearance; but the leaflets are larger towards the outſide of the head, till they become at length like the leaves on the ſtem, only ſmaller. Flowers very ſmall, ſhort, divided into five roundiſh ſegments, commonly plaited and converging, and ſeldom expanding till about noon, when the ſun ſhines hot: they are of a blue colour, but ſoon wither and become brown or black. Capſules membranaceous, depreſſed, roundiſh four-cornered, two-celled, with two ſeeds in each; theſe are ſmall, with a ſmooth even ſurface, ſwelling on the back, but the two other ſides flat. The membranous partition of the capſule not being faſtened to the ſides, but looſe in the middle, ſtrictly ſpeaking the capſule is rather one-celled than two-celled. The ſtems are long and thick, and yield a milky juice on being cut or broken. It is an annual plant, flowering in ſummer, (july) and is a native of the farther Carolina[b].

It was cultivated in 1732, by James Sherard, M. D.[c]

25. Flowers as in the preceding ſpecies, ſmall and converging, but white; and beſides theſe, others larger and more bell-ſhaped, the latter from bell-ſhaped end in a funnel-ſhaped form, are divided at the edge into five bifid ſegments, and are whitiſh, or of a very pale purple colour. Calyx divided to the baſe into five broadiſh hairy ſegments, and each calyx having a ſmall leaf, the heads of flowers are leafy; theſe leaflets are narrower within, wider without, and are larger than in the preceding ſpecies. Five or ſeven flowers come out alternately in each head. The heads are very hairy at the baſe, and ſo are the ſtems, and the leaves on both ſides, but the hairs on the edges of theſe are leſs conſpicuous. Capſules as in the preceding, with the ſame number of ſeeds, which are villoſe, mouſe-coloured, bluntly three-ſided, rounded on the back, angular on the ſides[d].

[x] Vahl. [y] Linn. ſpec. [z] Hort. kew. [a] Loureiro. [b] Dillenius. [c] Hort. kew. [d] Dillenius.

Native of the Eaſt Indies. Cultivated in 1732, by James Sherard, M.D. It flowers in auguſt[e].

Theſe two ſpecies with aggregate flowers, differing ſo much from the others, are placed in a diſtinct genus by Dillenius, under the name of *Volubilis*.

Some of the ſpecies of Ipomoea indeed differ more from others than they do from ſome ſpecies of Convolvulus, from which genus this can ſcarcely be ſeparated; that, however, is too unwieldy already to admit of unneceſſary enlargement, and the Ipomoeas are, to a botanical eye, ſufficiently diſtinct in their habit to be kept together, and ſeparate from Convolvulus.

26. Native of the Cape of Good Hope.

27. The fruit of this is properly a Berry, globular, fleſhy, mucronate at top, either quite round or obſcurely four-cornered, pale green, ſmooth: rind of a moderate thickneſs, fleſhy, eaſily ſeparable from the pulp, which is ſpongy, four-celled, or by abortion two-celled; the cells cloathed with their proper membrane, but not cohering with the ſeeds. Theſe are ſolitary, in the two-celled berries two, plano-convex; in the four-celled four, convex on one ſide, angular on the other, cinereous brown: outer covering leathery, thick, ſmooth. It differs from the other Ipomoeas, except n. 10. in ſtructure of the pericarp, above deſcribed, and alſo in the circumſtance given in the ſpecific difference.

Native of Ceylon, where it is named *Kiritella*[f].]

PROPAGATION AND CULTURE.

1. This is a tender plant, and will not thrive in the open air in England; it is propagated by ſeeds, which ſhould be ſown on a hot-bed in the ſpring; and as the plants will ſoon appear, they ſhould be each tranſplanted into a ſmall pot filled with light earth, before they twine about each other, for then it will be difficult to diſengage them without breaking their tops. When they are potted, they ſhould be plunged into a new hot-bed, and ſticks placed down by each plant for their ſtalks to twine about; after they have taken new root, they ſhould have a good ſhare of air in warm weather to prevent their drawing up weak; and when they are advanced too high to remain under the frame, they ſhould be removed into the tan-bed in the ſtove, where they ſhould have ſupport, for their branches will extend to a conſiderable height. They will begin to flower in june, and there will be a ſucceſſion of flowers till the end of ſeptember, and the ſeeds will ripen well in this ſituation every autumn.

5, 7. If the ſeeds of theſe ſorts are ſown on a hot-bed in the ſpring, and when the plants come up, if they are gradually hardened, and afterward tranſplanted into a warm border, in favourable ſeaſons they will flower and produce good ſeeds; but moſt people raiſe the plants on a very gentle hot-bed, and tranſplant them afterwards into another; by which method they are brought forward, and will perfect their ſeeds earlier.

8. This is a perennial plant, but too tender to thrive in the open air in England; the ſeeds of this muſt be ſown upon a hot-bed in the ſpring, and when the plants come up, they muſt be tranſplanted into ſeparate pots, and plunged into a freſh hot-bed; but as they will ſoon grow too tall to ſtand under a frame, they ſhould be removed into the bark-ſtove, where they muſt be ſupported, otherwiſe they will twine about all the neighbouring plants. As theſe plants extend their ſhoots to a very great length, they require a tall ſtove, where they may have room to grow, without which they will never produce any flowers. I have had theſe plants ſeveral years, but have only ſeen one flower produced from them; for they grow ſo very large before they begin to have flowers, as that few of the ſtoves in England have height enough for their growth.

9, 20, 23. Theſe are alſo tender, ſo the plants muſt be raiſed on a hot-bed in the ſpring, and afterwards planted in ſeparate pots, plunging them into another hot-bed; where they may remain till they reach the glaſſes, when they ſhould be removed into a glaſs caſe where they may have room, and be ſcreened from the cold, but ſhould have a large ſhare of free air admitted

[e] Hort. kew. [f] Gaertner.

to them in warm weather; with this treatment the plants will flower and produce ripe ſeeds.

Celoſia fol. lanceolato-ovatis, paniculâ diffuſa filiformi. *Gron. virg.* 144. 35.

DESCRIPTION, *&c.*

Perennial. Stems weak, requiring ſupport, riſing ten or twelve feet high, (Sloane and Browne ſay two or three) having large knots at each joint, with oval-lanceolate (or oval entire,) ſmooth leaves. Stems very diffuſed, branching out on every ſide. Flowers terminating, in ſlender looſe panicles, covered with a filky down, and of a pale yellow colour; theſe appear in july and auguſt, and in warm ſeaſons the ſeeds will ripen in autumn.

[According to Sloane, the ſtems are cornered, yellowiſh green, hollow, ſmooth, needing ſupport, but not twining, as big as a gooſe quill, having few joints, and at them leaves, which are oppoſite, an inch and half long, and half as broad near the round baſe, ending in a point, and of a yellowiſh green colour.

Browne deſcribes it with male and female flowers ſeparate. Swartz on the contrary never found it but with hermaphrodite flowers. He thinks it very nearly allied to Celoſia, if not a ſpecies of that genus. He thus deſcribes it.—Root annual. Stem upright, from a foot to a fathom in height, divided at top, round, ſtriated, ſmooth, looſe, jointed at the inſertion of the branches, joints ſwelling: branches oppoſite, ſpreading a little. Leaves oppoſite, petioled, lanceolate or ovate-lanceolate, acuminate, ſmooth. Panicles terminating, branched; branches diffuſed, alternate, ſpreading: flowers in a ſort of ſpike, on ſhort peduncles, ſmall, ovate, whitiſh; at the baſe of the flowers are extremely minute, ſhining, yellowiſh, imbricate ſcalelets. Calyx or corolla five-cleft, with acute upright ſegments. Filaments ſhorter than the corolla. Germ roundiſh. Style very ſhort, trifid. Stigmas reflex. The calyx inſtead of a capſule incloſes a black ſhining ſeed. A white wooll burſts out from among the ſcales after the flowering is paſt.] Native of Jamaica, and moſt of the other iſlands in the Weſt Indies, [among ſhrubs, chiefly in a cretaceous ſoil. It was cultivated by Mr. Miller before 1768.

DESCRIPTIONS, *&c.*

Root bulbous or fleſhy, in a few ſpecies tuberous and fibrous. Scape round, angular or compreſſed; ſimple or divided, few-flowered or many-flowered, ſhorter than, equal to, or longer than the leaves. Leaves ſheathing, equitant, naked (or very ſeldom rough-haired); entire, ſometimes waved, curled or ſpiral; enſiform, linear-enſiform, linear, or linear-filiform; in one inſtance quadrangular; longer than the ſtem or ſcape, equal to it, or ſhorter. Flowers one, two, three or more, but the number inconſtant, flowering one after another, of a great variety of colours, white, yellow, blue, purple, or variegated. The corolla is uſually ſix-petalled, with the petals divided to the very baſe; ſometimes, however, they cohere ſo ſlightly at bottom, that they have been reputed by ſome botaniſts (Knauth, Ruppius, &c.) as monopetalous; but they do not cohere by their entire claws as in monopetalous flowers properly ſo called. The filaments often cohere more or leſs (as in monadelphous, flowers), eſpecially in the african ſorts; but in other ſpecies they are perfectly free and diſtinct. The capſules in moſt of the ſpecies are trigonal, but in ſome are hexagonal.

The Iris is an inhabitant of every quarter of the world; America, however produces very few; ſeveral are found natives of the colder regions of Aſia; more ſtill of Europe; and moſt of the Cape of Good Hope.

1. Bulb ovate, fibrous, netted, the ſize of a hazle nut. Scapes ſeveral, moſt of them concealed by the ſheaths of the leaves, and a ſingle one only flowering: this is wholly ſheathed by leaves, ſimple, compreſſed, weak, white, ſmooth, upright, one-flowered, a palm in height. Leaves radical, about ſix, convoluted at the baſe, alternately ſheathing the ſcape to the very top, acuminate, from upright, ſpreading, or curved back, nerved, ſmooth, entire, nearly equal to the ſcape, the inner ones gradually ſhorter, and more convoluted. Corolla yellow; the ſmaller petals obovate; the inner lip of the ſtigma bifid, the ſegments briſtle-ſhaped, the length of the ſtigma. Capſule three-cornered, three-grooved. Native of the Cape of Good Hope, on the hills near Cape Town.

2. Bulb ovate, netted, the ſize of a large pea. Scape ſimple, ſheathed with leaves, upright, a palm in height. Leaves about four, alternately ſheathing, ſubfalcate-reflex, entire, ſmooth, equalling the ſcape, the upper ones gradually ſhorter. Corolla yellow, the ſmaller petals lanceolate. Native alſo of the Cape, on Leuweſtart mountain near Cape Town. Theſe were both firſt obſerved by Chevalier Thunberg[a].

3. Root browniſh on the outſide, white within, knobbed, with pale fibrils. Leaves acute, ſometimes ſhorter, ſometimes longer than the flower. Stem or ſcape very ſhort, often ſcarcely an inch in length. Germ oblong, bluntly and obſcurely three-cornered, an inch long, incloſed within two ſpathes, ending in the tube of the corolla, which is ſlender, and from two to three inches in length. All the petals are almoſt entire, blue or purple, varying much in colour, ſo much that the ſame flower changes, and from blue becomes more and more red. Outer beards blue, inner white, with yellow rips. Anthers blue. Stigmas deeply bifid and acuminate, uſually of the ſame colour with the corolla. The fruit is ſeldom obſerved in this ſpecies; it is ovate, bluntly three-cornered, an inch long. Seeds wrinkled, angular, yellow-ruſt-coloured[b].

Thunberg remarks that the ſcape is ſheathed with leaves; which are about five in number, alternately ſheathing, ſtriated, ſmooth, equalling the ſcape.

Native of Auſtria and Hungary on open hills, flowering in april[c]. It was cultivated in 1596 by Gerarde[d].

There are many varieties of this ſort, with white, ſtraw-coloured, pale blue, bluſh-coloured, yellow-variable, blue-variable, and other colours in the flowers, which are now in great meaſure neglected[e].

4. Scape ſimple, round, grooved, a ſpan high. Leaves alternate, ſheathing, upright, very finely ſtriated, obſcurely waved. Corolla the largeſt of all the ſpecies, very thin. The claws of the larger petals purple on the outſide, dotted and ſtreaked with purple within, border ſuborbiculate, waved, bent in at top, upright: border of the ſmaller petals ovate, bent down, with the edge frequently bent back, blunt, of the ſame colour with the larger ones, but ſhorter and narrower; the claws bearded within from the flexure to the baſe with browniſh-yellow cilias. Stigmas of the ſame colour with the petals: inner lip very blunt; outer bifid, ſegments ovate, crenulate, bent back. Capſule obſcurely three-cornered, with a long point and a wide top, marked with three purple lines[f].]

Mr. Miller obſerves, that the leaves are of a graviſh colour, that the ſtalks are two feet and a half high, that the three upright petals of the flower are almoſt as broad as a hand, but very thin, ſtriped with black and white; the three bending petals or falls of a darker colour, whence ſome gardeners call it the Mourning Iris. It flowers at the end of may or beginning of june, but never bears any ſeeds in England.

Native of the Levant. It takes the name from Suſa in Perſia. Cluſius informs us that this magnificent Iris was brought from Conſtantinople to Vienna and Holland in 1573. *In 1596* it was cultivated by our Gerarde[g].

5. Scape round, ſtriated, ſimple, upright, a foot high and more, bearing two or three flowers. Leaves nerved, ſubfalcated, obſcurely curved on the outer edge. Lower petals connate at the baſe: the claws of the larger ones thickiſh, with a thin winged edge, an inch long, green on the outſide, bearded within, with white cilias yellow at the tip: border blunt, emarginate, an inch wide, a little more in length, hanging down, white, ſtriated near the flexure. Smaller petals oblong, from upright bent in with a reflex margin, blunt, emarginate, white; claws thickiſh, attenuated, greeniſh. Anthers white. Stigmas ſnowy white, the ſame length with the claws of the larger petals; inner lip very blunt, outer bifid, ſegments acute, crenulate, upright. Capſule three-grooved, having a point an inch in length, ſomewhat compreſſed, two-grooved, obſcurely trigonal.

[a] Thunb. diſſ. p. 8. [b] Jacquin. [c] Ibid.
[d] Hort. kew. [e] Park. parad. and Curt. magaz.
[f] Thunberg. [g] Hort. kew.

It

It reſembles I. germanica very much, but differs in having the petals white and entire, the edges of the ſmaller petals reflex at the baſe, the larger ones more upright, and the lip of the ſtigma crenated and more upright [b].

Native of the South of Europe. Cultivated in 1596 by Gerarde. It flowers in may and june [i]. This is named by our old writers White Flower de-luce, or Flower de-luce of Florence. The preceding is called by them Turky Flower de-luce from the French *Fleur-de-lys*.

6. Scape ſimple, ſtriated, longer than the leaves, a ſpan in height, ſuſtaining two or three flowers, ſometimes four. Leaves ſubfalcated, acute, ſtriated, from erect patulous. Petals violate coloured, entire. Capſule cylindric, with three ſtreaks [k]. Native of Portugal and Spain. Cultivated in 1596 by Gerarde. It flowers in april and may [l]; and again in autumn, whence it had the name of *biflora* [m], but improperly becauſe it tends to miſlead. It ſhould have been *biflorens*, or more claſſically *bifera*. I have therefore named it *Twice flowering Iris*.]

7. This has three or four large bright-purple flowers, which ſtand above each other, and have purpliſh ſheaths; the three bending petals or falls are ſtriped with white from the baſe to the end of the beard. The capſules are large, blunt and triangular. It flowers at the end of may, and the ſeeds ripen at the beginning of auguſt. [Its native place of growth is unknown.

8. Scape ſtriated, ſcarcely longer than the leaves, a foot and more in height. Leaves acute, ſtriated, upright, the lower ones the length of the ſcape, but the upper ones gradually ſhorter. Flowers at the top of the ſcape divided, alternate, coming out ſucceſſively, handſome, yellow, netted with black [n]. The upper part of the ſtem is naked, and divides into three branches, each of which has two or three flowers one above another: the three upright petals or ſtandards are yellow, and the bending petals or falls are variegated with purple ſtripes. It flowers in june, but is rarely ſucceeded by ſeeds in England. Native of Hungary. [Cultivated by Gerarde in 1597 [o]. He calls it Variable Flower de-luce.

9. Scape divided at top, larger than the leaves. Leaves reflex-falcated, nerved, an inch wide. Flowers blue, with the ſmaller petals quite entire [p].]

This has the largeſt leaves of any of the ſpecies; They are of a greyiſh colour and ſpread wide, embracing each other at their baſe, where they are purpliſh. The ſtalks riſe near four feet high, and divide into ſeveral branches, each ſupporting three or four flowers, which are covered with a thin ſheath; the three bending petals or falls are of a faint purple inclining to blue, with purple veins running lengthwiſe: the beard is yellow, and the three erect petals or ſtandards are of a bright blue, with ſome faint purple ſtripes; the flowers have an agreeable ſcent.

[Native of Germany, Switzerland and Dauphiné.—Cultivated in 1596 by Gerard. It flowers in may and june [q].

10. Outer petals bent back, very dark purple, with yelloviſh ſtains below the middle; beard yellow. Inner petals obovate-oblong, a little ſhorter than the outer ones, with a purpliſh border, and a dirty yellow claw. Stigmas dirty yellow, pale purpliſh above. It may perhaps be no more than a variety of I. ſambucina, but it is totally void of ſmell. Native of the South of Europe. Cultivated by Mr. Miller in 1758. It flowers in april [r].

11. Scape divided at top, longer than the leaves, two (or three) feet high. Leaves inflex-falcated at top, ſtriated, the upper ones gradually ſhorter. It reſembles I. germanica, from which, however, it differs in having the larger petals of a deeper violet colour, and ſubemarginate; the ſmaller petals emarginate, and of a deeper blue colour; the ſtigmas acute and ſerrate, with a blueiſh keel [s]. It derives the trivial name from the ſmell of the flowers, which is very like that of Elder in bloom [t]. It flowers at the end of may, and in june; is a native of the South of Europe; and was cultivated in 1748, by Mr. Miller [u]. Mr Curtis takes it to be the ſame with Iris Camerarii of Parkinſon (parad. 181.); and if ſo, it was probably known to our gardens in his time.]

12. The roots of this are very thick, fleſhy, and divided into joints, ſpreading juſt under the ſurface of the ground; they are of a browniſh colour on their outſide, but white within; the leaves ariſe in cluſters, embracing each other at their baſe, but ſpread aſunder upwards in form of wings; they are a foot and a half long, and two inches broad, having ſharp edges, ending in points like ſwords; the ſtalks between theſe, which are a little longer than the leaves, having at each joint one leaf without a foot-ſtalk; theſe diminiſh in their ſize upwards; the ſtalks divide into three branches, each of which produces two or three flowers one above another at diſtances, each incloſed in a ſheath; they have three large violet-coloured petals which turn backward, and are called falls; theſe have beards near an inch long on their midrib towards their baſe, and have a ſhort arched petal which covers the beard, with three broad erect petals of the ſame colour, called ſtandards; the ſtamina lie upon the reflexed petals. Under each flower is ſituated an oblong germ, which turns to a large three-cornered capſule, filled with large compreſſed ſeeds. This flowers in june, and the ſeeds ripen in auguſt.

There is a variety of this with blue ſtandards and purple falls, and one with pale purple ſtandards, another with white, and a third with a ſmaller flower, but theſe are accidental varieties which have come from ſeeds.

[It differs from I. germanica, to which it bears ſome reſemblance, in having the larger petals folded back in the middle, of a deeper violet colour, with white or yelloviſh veins, and blueiſh in the middle; and the ſmaller petals and ſtigmas of a ſqualid yellow colour, and emarginate. The ſcape is divided at top, that is, the lower flowers are pedunculed, it is ſtriated, and about two feet high. The leaves are ſharp and nerved [x].

Native of the South of Europe. Cultivated by Mr. Miller in 1768 [y].

13. Stem frutеſcent, compreſſed, ſmooth, branching dichotomouſly, jointed, decumbent, ſomewhat upright at top, bracted, a foot high and more; branches alternate, elongated, like the ſcape, one-flowered. Bractes or ſpathes on the ſtem and branches alternate, compreſſed with a ſharp keel, ſmooth, membranaceous at top, an inch long, ſhorter than the internodes. Leaves acute, nerved, ſhorter than the ſtem, a foot long. Corolla white; claws of the larger petals a little widened, bearded within, dotted with yellow. A yellow ſpot in the flexure. Border blunt. Claws of the ſmaller petals only half the width of the others, and without any ſpots: borders oblong, blunt, upright. Filaments connate at the baſe, awl-ſhaped, white. Stigmas blueiſh-white; outer lip crenulate, inner bifid; ſegments lanceolate, upright, ſhorter than the petals. Native of Africa, in the interior country of the Hottentots [z].

14. Root tuberous, creeping. Stems ſeveral, ſhort, inclining upwards, compreſſed, leafy. Leaves ſcarcely ſix inches long, ſharpiſh, a little curved like a ſickle at the tips, entire, with a pale membranaceous margin. Flower generally ſolitary, a little ſhorter than the leaves, erect, of a pale purpliſh blue: outer petals drooping, obtuſe, blue, with deeper blue ſpots, creſted in the place of the beard with three longitudinal, elevated, waved ribs, variegated with orange and yellow; inner petals narrower, pointed, uniform in colour. Stigmas of the ſame colour as the petals, and half as long [a].

Native of North America, whence it was ſent by Mr. Peter Collinſon in 1756. It flowers in may [b].

15. Stem round, ſmooth, branched. Branches ſimple, elongated, naked, ſpreading very much, three-

[b] Hort. kew.

flowered or thereabouts. Leaves radical, fix or ſeven, embracing, diſtich, ſhort; there is a very ſhort ſtem-leaf at each ramification. Flowers on long peduncles, pale purple, the ſmalleſt of any in the genus[a].

Native of Siberia. Introduced in 1784 by Mr. John Bell. It flowers in auguſt[a].

16. Bulb ſtriated, globular, fibrilled. Leaf ſingle, ſheathing, channelled, ſmooth, nerved, looſe, hanging down, twice the length of the ſcape; which is ſingle, upright, round, jointed, moſtly one-flowered, ſmooth, a foot high: joints embraced by bractes reſembling ſpathes. Flower terminating, ſolitary. Spathe two-valved, embracing the peduncle; the lower ſhorter, acute, ſmooth. Within this lies the unfolded flower, with two very thin, linear-oblong bractes. Corolla blue, with a yellow joint: claws of the larger petals broader, linear, dotted on the inſide with blue, having a nectareous hollow at the baſe; border ovate, acute, very pale blue, with the joint bearded: claws of the ſmaller petals very narrow, convex on the outſide, frequently having two oppoſite teeth below the joint; border from jointed ſpreading, linear awl-ſhaped: all the claws connate at the baſe, and inſerted into the germ. Filaments half the length of the tube, connate at the baſe. Anthers yelloviſh. Germ ovate, ſix-grooved. Style three-cornered, incraſſated, ſmooth. Stigmas linear: outer lip blunt, inner very long, acute, almoſt the length of the border.

Native of the Cape of Good Hope near Cape Town, Picketberg, &c.

17. Bulb the ſize of a hazel nut. Scape ſimple, round, jointed, upright, bearing one or two flowers, a foot and half in height. Leaf ſingle, nerved, upright, with the tip hanging down, two feet long. Border of the larger petals white, ſuborbiculate, with a point; claws green on the outſide, yellow within, dotted with black. Smaller petals ſeveral times ſhorter and leſs: claws convex on the outſide, green, concave within, dotted with brown, the length of the larger ones, but narrower; ſegments lanceolate, divaricating, a line in length, the middle one of the three a little longer, white dotted with brown. Inner lip of the ſtigma bifid, the clefts ovate, blunt, only half the length of the larger petals, white, upright. It varies in the ſhape of the larger petals, and very much in the colours, blue, purple, yellow, white, and ſpotted.

Native of the Cape, on the hills below Duyvelſberg, in Swartland, and near Bergrivier[a].

Mr. Curtis, when he figured this ſpecies under the name of *I. paronia* (*magaz. t.* 168.) had his doubts whether it was the *paronia* of the *Syſtema vegetabilium*. He deſcribes it as a ſmall delicate Iris, about a ſpot and half high, with very narrow leaves, bearing on the top of the ſtalk one, or at moſt two flowers; three of the petals large and white, with a brilliant blue ſpot at the baſe of each, edged on the outer ſide with deep purple; the delicacy of the flower, and the eye-like ſpot at the baſe of three of the petals, render it one of the moſt ſtriking plants of the genus. His figure is from a plant that flowered with Meſſ. Grimwood and Co. in june 1794; and they received it from Holland.—It had flowered, however, before in the Royal botanic garden at Kew, namely in 1776[f].

18. Scape jointed, flexuoſe, almoſt upright, branched at top, bracted, from a hand to a ſpan in height. Leaf linear, from reflex ſpreading, ſhorter than the ſcape. Petals connate at the baſe: claws of the larger ones obovate, greeniſh on the outſide, with a thinner blue edge; pale blue within; a yellow ſpot, three-toothed, and the beard in a double line; borders blunt, violet, alternately a little narrower and ſhorter. Anthers ſaffron-coloured in front, black at the tip and on the back. Stigmas pale blue, ſhorter than the borders of the petals, cowl-two-lipped: outer lip linear, awned at the tip with five or ſix ſhort briſtles, and curved in; the inner ſhorter, briſtly-multifid, like the petals of Dianthus plumaris. Sometimes, but very ſeldom, the ſcape is one-flowered, but it is moſtly branched, with one-flowered and three-flowered branches.

Native of the Cape of Good Hope below Duyvelſberg[c].

19. Xiphium or bulboſe-rooted Iris has the leaves channelled and convoluted, not only at the baſe, as in the other ſpecies, but the whole length of them; they are awl-ſhaped at the tip, and ſhorter than the ſcape. The flowers are blue, with emarginate petals[a].]

Mr. Miller makes two diſtinct ſpecies, which are here given as varieties. The *latifolium* (our *a*) he ſays, has much larger roots, with larger leaves, the flower-ſtalk is near twice the height, and the flowers are more than double the ſize.

There are many varieties of theſe, the moſt common colour is blue, deeper or lighter; but it is alſo yellow, white, blue with white or yellow falls, violet-coloured with blue falls, variegated, &c.

[Native of the South of Europe.—Dr. Naſh, in his hiſtory of Worceſterſhire, informs us, that it was diſcovered by the late Dutcheſs Dowager of Portland by the river ſide near Fladbury, and in other parts of that county[i].

Gerarde cultivated it, and ſays that he received it from his brother James Garret, Apothecary. He ſays, "it is daſht over, inſtead of the blew or watchet co-"lour, with a moſt pleaſant gold yellow colour, and "is of ſmell exceeding ſweet."

20. Root fleſhy, the thickneſs of the thumb, ſpreading horizontally near the ſurface, blackiſh on the outſide, reddiſh and ſpongy within, the upper part covered with numerous rigid fibres, the lower part ſending down many long, whitiſh, wrinkled, ſtringy roots. Leaves from the root, two or three feet long, upright, an inch or more in breadth, ſtriated, having a prominent longitudinal midrib, equal to the ſcape, deep green, ſmooth: ſtem-leaves ſhorter, forming a ſheath at the bottom. Scapes from one to three feet in height, upright, alternately inclined from joint to joint, round or flatted a little, ſmooth and ſpongy. Peduncles axillary, flat on one ſide, and ſmooth; each ſuſtaining two or three flowers, the two outer (when there are three) having one ſheath, and the middle flower two. Corolla yellow: the three outer petals large, roundiſh-ovate, reflex, one-toothed on each ſide, ſtreaked with purple lines at the baſe of the lamina, and having two ſmall holes at the bottom of the claw. Anthers yellow with purpliſh edges, two celled, opening beneath. Germ three-cornered, the angles blunt and grooved. Stigma much larger than the ſmall petals, yellow, cut into fringed ſegments at the top[k]. Dr. Withering ſays he ſhould be tempted to deſcribe the flower as having nine petals, and three ſtyles connected longitudinally to the three innermoſt petals.

It is common in moſt parts of Europe, in marſhy meadows and fens, by the ſides of rivers, brooks, lakes, pools and ditches, flowering at the end of june, or the beginning of july.

It is called by Engliſh writers water Flower de-luce, Yellow Flag, Water Flag, and provincially Skeggs or Lugs.]

21. Root thick, tufted, fibrous. Leaves graſs-green, when broken emitting a ſtrong odour, not much unlike that of hot roaſt beef at the firſt ſcent, but if ſmelt too cloſe, becoming diſagreeable: [Dr. Withering compares the ſmell of them to rancid bacon. They are acute and nerved, rather ſhorter than the ſcape; which is ſingle, cylindrical, but angular on one ſide, jointed, ſheathed with alternate ſpathaceous leaves, two feet high, bearing ſeveral flowers. Corolla of a lurid purpliſh aſh colour, not ſmelling in the night time: claws of the outer petals wrinkled and plaited on the under ſurface: inner petals larger than the ſtigmas, ſpreading[l].

Native of France, Italy, England: as near Hornſey; about Charlton wood, and between Eltham and Chiſlehurſt in Kent; near Braintree and Woodford in Eſſex; Bath hills, Ditchingham, Norfolk; near Cherry-Hinton, Teverſham, Fulborn and Triplow in Cambridgeſhire; between Dunſtable and St. Alban's; near Perſhore in Worceſterſhire; and in all the South Weſt

[a] Thunberg. [b] Hort. kew. [c] Thunberg. [d] M. S. Soland. [e] Thunberg. [f] Ibid. [g] Withering. [h] Curtis. [i] Linneus.

counties

counties very common: on hedge banks and ſloping ground: flowering from the end of june to auguſt. It runs much at the root and flowers ſparingly. In Engliſh it is named Stinking Iris or Flower de-luce, Stinking Gladwyn or Gladdon.

22. Root white within, black without, the thickneſs of the thumb, having white fibres, and briſtly at top, with the remains of leaves. Scape compreſſed, upright, jointed, ſheathed with alternate leaves, many-flowered, the length of the leaves, or a little higher, a foot in length. Leaves narrow, ſharp, curved in at the tip, nerved and ſmooth, as is the whole plant. Spathes membranaceous, acute, brownish, ſhorter than the peduncles, very thin at the edge and tip. Peduncles two or three inches long, round, ſlender, upright, one-flowered. Flowers elegant, but without ſcent. Claws of the outer petals channelled, green on the outſide, yellow on the inſide, ſtreaked with dark purple; border flat, rounded-ovate, blunt, quite entire, pale at the baſe, then blue with deep-blue ſtreaks: inner petals ſpatulate, blunt, upright, ſhorter, bluer and ſtreaked. Stigmas bifid, blunt, of the ſame colour with the inner petals. Anthers violet-coloured [m].

Native of Virginia. It flowers here in june and july;—and was cultivated by Mr. Miller in 1758 [n].

23. Scape jointed, bifid at the top or ſimple, many-flowered, higher than the leaves, two feet in length. Leaves alternate, ſheathing; the upper ones gradually ſhorter. Flowers blue, large [o].

Dillenius has deſcribed and figured two varieties of this, the firſt with the ſtigmas not crenated, and the ſecond with the ſtigmas crenated; they differ alſo ſomewhat in colour.

Mr. Curtis remarks that this ſpecies has, for the moſt part, a ſtalk unuſually crooked or elbowed, that it is the *pitta* of Mr. Miller, and that the *verſicolor* of Miller is probably the *fibirica* of Linneus.

It is a native of North America, and was cultivated in 1732 by James Sherard, M.D. It flowers in may and june [p].

24. Scape round or roundiſh, covered with the ſheaths of leaves, many-flowered, longer than the leaves, a foot high. Leaves falcated, acute, ſtriated, nerved. Spathes membranaceous at the edge. Larger petals dilated at the baſe with duſky veins; leſſer ſnowy-white, with yellowiſh veins at the baſe. Stigmas ſnowy-white. Capſule hexagonal, with blunt angels [q].

This being the higheſt of the ſpecies of Iris cultivated in our gardens, Mr. Curtis has named it *Tall Iris*.

Notwithſtanding Mr. Miller's deſcription of his *orientalis* accords very badly with this, they have been generally conſidered as the ſame plant, diſtinguiſhed by the name of *Pococke's Iris*, Dr. Pococke having firſt introduced it, according to Mr. Miller, from Carniola; but that is probably a miſtake, for it is a native of the Levant [r]; and Mr. Miller accordingly names it *orientalis*.

It was cultivated by Mr. Miller in 1759 [s]. It flowers in july.

25. Long-leaved Iris is a native of Siberia, and was introduced in 1780 by Chevalier Pallas. It flowers from july to ſeptember [t].

26. Scape ſimple, many-flowered, a foot high. Leaves two, or one only, from the middle to the end gradually but much attenuated, margined, nerved, ſtriated, rigid, ſmooth. Spathes like the leaves, but broader, membranaceous at the tip, a ſpan long.—Native of the Cape of Good Hope, in Hauteniquas near Wolfwekraal, and Langekloof near Keurbooms river [u].

27. Stem round at bottom, the thickneſs of a finger, very much branched at top, and many-flowered. Branches ſubtrichotomous, panicled, compreſſed and angular, flexouſe, ſmooth. Root-leaves with long ſheaths, nerved, attenuated at the tip, ſmooth, about the ſame length with the ſtem. Stem-leaves gradually ſhorter, and dwindling into ſpathes. Flowers yellow, ſmall. Bractes at the ramifications ovate, acute, membranaceous, ſhorter than the branches and peduncles. Native alſo of the Cape, in the ſands of Swartland [x].

28. Root compoſed of two bulbs, one over the other, as in Gladiolus and Crocus. Scape very ſhort, ſimple, the whole ſheathed with leaves, a finger's length. Leaves ſeveral, attenuated at the tip, reflex, waved, longer than the ſcape. Petals purple, with a yellow ſpot in place of the beard [y].

Native of Spain and Portugal. Cultivated in 1597 by Gerard. It flowers in may [z]. Gerarde and Parkinſon name it Spaniſh Nut. Ray found it in Sicily flowering in the month of april.]

29. This has tufted fibrous roots, from which ariſe many graſs-like leaves about nine inches long; from between them come out the ſtalks, which are ſhorter than the leaves, and ſupport one purple flower with blue ſtandards. It flowers in may, but ſeldom produces ſeeds in England.

[Scape covered with alternate ſpathes, ſimple. Leaves linear, nerved [a]. Native of North America. Cultivated by Mr. Miller in 1739 [b].]

30. Perſian Iris has an oval bulbous root, from which come out five or ſix pale-green leaves, hollowed like the keel of a boat, about ſix inches long, and one inch broad at the baſe, ending in points. Between theſe the flower-ſtalk ariſes, which is ſeldom above three inches high, ſupporting one or two flowers, incloſed in ſpathes: theſe have three erect petals or ſtandards, of a pale ſky-blue colour, and three reflexed petals or falls, which on their outſide are of the ſame colour, but the lip has a yellow ſtreak running through the middle, and on each ſide are many dark ſpots, with one large deep-purple ſpot at the bottom.

[Linneus remarks, that the bulb puts forth a gem from two pairs of ſcales, between which are the leaves and a ſingle flower in a ſimple ſpathe; that the leaves are ſubulate-channelled, and longer than the ſtem.

The leaves are ſtriated and nerved, unequal, and a ſpan in length. The larger petals are oblong, blunt, waved, ſubemarginate, convoluted; having a yellow line along the middle, with violet-coloured dots, and ſpots of the ſame at the tip: the ſmaller petals are linear oblong, patulous, white, convoluted: each lip of the ſtigma upright, pale blue; inner bifid, with lanceolate ſegments [c].

Native of Perſia. Cultivated here in the time of Parkinſon (1629.) [d], who remarks that it was then very rare, and ſeldom bore flowers.]

The Perſian Iris is greatly eſteemed for the beauty and extreme ſweetneſs of its flowers, as alſo for its early appearance in the ſpring, it generally being in perfection in february or the beginning of march, according to the forwardneſs of the ſeaſon. [Like the Hyacinth and Narciſſus it will blow within doors in a water-glaſs, but ſtronger in a ſmall pot, or ſand or ſandy loam, and a few flowers will ſcent a whole apartment [e].

31. Bulb ovate, tunicated, ſmooth, fibroſe, the ſize of a hazel nut. Scape round, upright, almoſt ſimple, ſheathed, jointed, a ſpan or a little more in height. Leaf ſheathing the ſcape for a conſiderable length at bottom, acuminate, ſtriated, longer than the ſcape. Flowers terminating, one or two, upright. Outer ſpathe ſmooth, green with a red tip; the inner ones very thin, white. Claws of the larger petals yellow with the edge white, dotted with purple on both ſides; joint even, ſaffron-coloured, with a purple circle; border ovate, blunt, ſpreading, yellow within, purple-nerved on the outſide. Smaller petals lanceolate, blunt, yellow, ſtreaked with duſky purple on the outſide, narrowing gradually into the claws, all of which are connate at the baſe. Inner lip of the ſtigmas bifid; segments oblong, acute, the inner ſide ſtraight, the outer produced, erect, yellow. Capſule acutely three-cornered, blunt.

Native of the Cape of Good Hope, on the hills below Duyvelſberg and Lewekopp [f].

[m] Jacquin and Thunb. [n] Hort. kew. [o] Hort. kew. [p] Thunberg. [q] Hort. kew. [r] Thunberg. [s] Thunb. Hort. kew. Curtis. [t] Hort. kew. [u] Ibid. [x] Thunberg. [y] Ibid. [z] Hort. kew. [a] Thunb. [b] Hort. kew. [c] Curtis. [d] Thunb. [e] Hort. kew. [f] Thunberg.

32. Scape filiform, generally ſimple, but ſometimes divided and three-flowered, upright, from a hand to a ſpan in height. It has commonly only one leaf; (but ſometimes there are two) it is upright except at the tip, where it droops, and is twice as long as the ſcape. Flowers blue, ſmall.—Native of the Cape.

33. Scape ſimple, covered with the ſheaths of the leaves, which are few, but the ſheaths are broad. Flowers terminating, pale blue: outer lip of the ſtigma very ſhort and blunt: inner bifid, ſegments oblong. Capſule filiform, longer than the corolla.

Native of Siberia, in the ſands of Dauria, and near the Wolga [c].

34. This has narrow, flat, graſs-like leaves, about a foot long, of a light green colour; between theſe ariſe the ſtalks about ſix inches high, having two narrow leaves much longer than the ſtalks. Flowers two or three, ſmall: the petals have a broad yellow line with purple ſtripes: the three falls are of a light purple colour ſtriped with blue, and have a convex ridge running along them: the others are of a reddiſh purple variegated with violet: they have a ſcent like freſh plums. Capſule ſhort, with three borders or wings, [hexagonal by means of ſix deep grooves [k].

Native of Auſtria. Cultivated in 1597 by Gerarde. It flowers in june [l].

35. Root knobbed, blackiſh on the outſide, whitiſh within, with long pale fibres. Stem round very ſlightly compreſſed, ſtraight or a little flexuoſe, from two to three feet in height, taller than the leaves. Flowers commonly two, on ſhort peduncles, each involved in its ſpathe; ſometimes there are three; they have no ſcent. Colour blue-purple; but under the ſtigmas the reflex petals are more inclined to red: upright petals flat, and uſually quite entire.] Mr. Miller ſays that the flowers have light blue ſtandards, and purple variegated falls, having a broad white line in the middle inſtead of the beard. [Capſule oblong, acuminate, hexangular, three of the ſides alternately thrice the breadth of the other three [k].

Mr. Curtis remarks, that it is diſtinguiſhed by the narrowneſs of the leaves which emit a diſagreeable ſmell when bruiſed; by the fine rich purple colour of the flowers inclining to blue, and by its hexangular germs.

Native of Germany and Auſtria, in wet meadows. Cultivated by Mr. Miller in 1759. It flowers in july [l].

36. Scape a foot high or more, dividing at top, three-flowered or many-flowered, longer than the leaves; which are nerved and flat. Flowers blue in brown, ſcarioſe ſpathes [n]. The inner petals are upright. Germ trigonal, not grooved at the angles [o]. It is diſtinguiſhed from the other ſorts uſually cultivated in our gardens by the ſuperior height of its ſtems; and the narrowneſs of its leaves; by the latter circumſtance however, it is often confounded with the *graminea* [n].

Native of Siberia, Auſtria, and Switzerland. Cultivated by Gerarde in 1596. It flowers in may and june [p].

37. Root oblique, knobbed, covered with brown filaments from the remains of the leaves, fibroſe beneath, above producing in joints abundance of ſmall narrow bulbs. Leaves linear-awl-ſhaped, the third part of an inch in breadth; root-leaves five, ſtem-leaves few, flexuoſe at the top or in the middle. Stem fiſtular, many-flowered. Spathe ferruginous, two-valved or many-valved. Flowers terminating, three; the middle one peduncled; the others, as alſo the lower ſolitary one, ſubſeſſile. Corolla white; the reflex petals have the border toothletted, the claw linear, yellow with violet-coloured veins; the upright petals ſhorter by half, wholly white, waved, with very narrow claws. Stigmas large, white, deeply bifid, crenated. Capſule ovate-oblong, trigonal, with wrinkled valves [q]. It approaches very near to the preceding ſpecies [r].

[c] Thunberg. [k] Jacquin. [l] Hort. kew.
[n] Jacquin. [o] Hort. kew. [p] Thunberg. [q] Linn.
[r] Curtis. [s] Hort. kew. [t] Murray in comm. got.
[u] Murr. in ſyſt.

38. Root ſolid, ſubbulboſe, ſurrounded by whitiſh fibres, and throwing out other tubers. Stem upright, roundiſh, two feet high, ſimple. Root-leaves acuminate, quite entire, ſomewhat rigid, diſtich, flat, keeled at the baſe, above ſimple, from upright ſpreading, few. Flowers few, coming out ſucceſſively from the ſame ſpathe, yellow, without ſcent, peduncled; the petals have a black ſhining glandular hole or pit, like that which is common to ſeveral ſpecies of Ranunculus.

Native of Martinico, in moiſt mountainous woody paſtures; flowering in november and december. It was raiſed from ſeed at Vienna about the year 1760, but had not flowered there in three years after [t].

Native alſo of the iſland of St. Lucia, whence it was introduced into the royal garden at Kew in 1782, by Mr. Alexander Anderſon. It flowers in june [t].

39. Scape round, jointed, villoſe, ſimple, a foot high, ſuſtaining one or two flowers. Leaf ſomewhat channelled, ſtriated, villoſe, the length of the ſcape. Spathes acute, ſtriated, ſmooth, two inches long. Peduncles ſubancipital, one-flowered, ſmooth. All the petals united at the baſe: the three outer ſeveral times bigger than the others, ovate, obtuſe, entire; the three inner much narrower and ſhorter by half, lanceolate, acute. Nectaries three within the larger petals; each an ovate, blunt leaflet, petal-ſhaped at the baſe. Filaments connected beyond the middle into a cylinder, linear-ſubulate, ſeveral times ſhorter than the corolla, purpliſh. Anthers preſſed cloſe to the ſtigmas, orange-coloured with two brown lines. Stigmas the length of the ſtamens. Capſule trigonal.

This beautiful flower is orange-coloured, with black ſpots and dots at the baſe, and a heart-ſhaped blue ſpot above the baſe, which at bottom is tomentoſe and black.

Native of the Cape of Good Hope, in Swartland and elſewhere among buſhes [u].

40. Scape grooved, flexuoſe, divided at top, a hand or more in height. Leaves radical, alternate, reflex, equal to or longer than the ſcape. Flowers terminating, alternate, the lower peduncled, three or four in number. Corolla ſix-petalled. Alternate petals larger, border ovate obtuſe veined, yellow and very finely dotted at the flexure: the ſmaller petals a little narrower, ſcarcely ſhorter than the others, like them and ſpreading. Anthers ovate, black; pollen orange burſting from the outer ſide. Outer lip of the ſtigma very ſhort, yellow; inner bifid, yellow, ſegments lanceolate, acute, the length of the petals. This varies in the colour of the corolla, yellow with blood-red veins, blue, and fleſh-colour.

Native of the Cape of Good Hope, on the hills near Cape Town [x].

41. Bulb ovate, coated, the ſize of a pea. Scape upright, hairy, divided, many-flowered, a hand in height. Leaves convoluted, flexuoſe and recurved, marked on the outſide with lines and hairy; within pubeſcent; the length of the ſcape or a little longer; the upper ones ſhorter; the uppermoſt ſpathe-form. Spathes in pairs, ſheathing, reſembling the leaves, hairy. Peduncles three-cornered, two together from the ſame point, three or five, incraſſated, ſmooth, unequal. Flowers expanding ſucceſſively. Claws of the larger petals broader, with a nectareous excavation at the baſe, green variegated; border ovate, acute, with a green circle at the knee: claws of the ſmaller petals linear, border ovate-oblong, acute: all the claws connate at the baſe. Inner lip of the ſtigmas bifid; ſegments oblong, acute. There are ſeveral varieties of this ſpecies alſo; as wholly yellow, except the green circle mentioned above; with the petals and piſtils red within, a yellow ſpot at the knee, and a duſky circle; and the larger petals yellow, with a green circle at the knee, the borders of the leſſer petals and inner lips of the ſtigmas blood-red.

This ſpecies differs from *I. ciliata* in having the whole leaves rough-haired, and the alternate borders of the petals ovate.

Common on the hills about Cape Town [y].

[x] Jacquin. [y] Hort. kew. [z] Thunberg. [a] Ibid.

42. Scape deeply radicate, round, flexuose, divided at top, a foot high. Leaf sheathing the scape at bottom for a great length, erect but hanging down at the tip, thrice the length of the scape. Flowers solitary or several, alternate, chiefly directed one way. Petals connate at the base. Filaments awl-shaped, white, connate at the base like the petals. Anthers grooved in front, yellow or white. Outer lip of the stigma obtuse quite entire: inner bifid, segments lanceolate, acute; notchletted on one side, which is produced from upright bent in, the length of the smaller petals. It varies with blue, white and yellow flowers, the first having dusky streaks, and the last spotted.

Common at the Cape, in the sands of Groenekloof, Swartland, the low plants near Cape Town, Duyvelberg, &c. [a]

43. Scape divided, almost upright, many-flowered a span in height. Branches or peduncles flexuose, spreading very much hirsute, from one to three-flowered. Leaves waved, nerved, hanging down at the tip, longer than the scape. Smaller petals narrower by half than the others, ovate-lanceolate: tube greenish, connate at the base: all the borders dull-coloured or ruescent, with a red keel, bright yellow at the bending. Anthers blue. Inner lip of the stigma bifid; segments lanceolate, with the keel blue on the outside, a little shorter than the borders.

Native of the Cape, below Duyvelberg, near Cape Town [b].

44. Scape round, divided at top, jointed, many-flowered, a foot and more in height. Leaves setaceous-attenuated at the tip, nerved, upright, equalling the scape. Flowers large handsome, blue with yellow at the flexures. Spathes scarious at top, jagged. It differs from I ramosa by its branched scape and simple peduncles.

Native of the Cape, between Sondagsrivier and Visshrivier [c].

45. Scape round, smooth, jointed, from flexuose upright, divided at top, glutinose, purplish, a foot high. Peduncles alternate, flexuose, glutinose, one-flowered. Leaves few, upright, longer than the scape. Borders of the larger petals ovate, blundtish, whitish at the flexure: smaller petals a little narrower and shorter; claws greenish white within and without. Inner lip of the stigma bifid; segments lanceolate, shorter by half than the borders of the larger petals: outer lip bifid, half the length of the other.

Native of the Cape, in Saldahna bay [d].

46. Scape jointed, from flexuose-upright, divided at top, glutinose, many-flowered, a foot and more in height. Leaf single, attenuated at the tip, striated, smooth, shorter than the scape. Spathes sheathing the joints, striated, smooth. Flowers solitary on peduncles. Peduncles from sheaths with the scape two, filiform, flexuose, spreading, viscid, an inch and more in length. Corolla reflex, yellow all over. The three larger petals blunt, with red dots at the flexure. Stigmas yellow: outer lip very small; inner bifid: segments lanceolate, acute, the length of the smaller petals.

Native of the Cape, near Bergrivier, &c. [e]

47. This has a tuberous root, as the name implies. There arise from it five or six long narrow four-cornered leaves, and from between these the stalk, supporting one small flower, of a dark purple colour. It flowers in april, but does not produce seeds in England.

[Native of the Levant. Cultivated in 1597, as appears from Gerarde [f].

Linneus remarks that this differs from its congeners not only in having tuberous roots and four-cornered leaves, but the three inner petals awl-shaped, and all parts of the flower very minute, the three segments of the stigma bifid beyond the middle, and the colour of the flower greenish.

48. Scape jointed, striated, smooth, upright, a foot high. Leaves nerved shorter than the scape. Spathes like the leaves, obverse, gradually shorter. Flowers from the axils of the spathes. Corollas one-petalled, white.

Native of Japan. Thunberg originally took it for the *squalens* of Linneus.

49. Scape striated, smooth, upright, a foot high or more. Leaves radical, nerved, smooth, attenuated at the tip, equal to the scape. Spathes like the leaves, gradually shorter. Flowers about two, subterminating. Corolla dusky-netted.

Native of Japan, where it was found by Thunberg, and supposed by him at first to be the same with I. fibrinea of Linneus.

50. In the Flora Japonica Thunberg took this to be I. graminea of Linneus; but the scape is round or columnar, not two-edged or ancipital; and the germs are hexagonal.

Native of Japan [g].

Uses of the Iris.

Most of the species are cultivated in flower-gardens for their beauty, and would attract more regard, were it not for the facility with which they are propagated.

Many of the African sorts, especially the *edulis*, furnish nutriment both to men and monkeys: the bulbs with the scapes collected in bundles and gently boiled are esteemed pleasant and nourishing.

The roots of Iris are recommended for their medical qualities by Dioscorides and the Arabians: those of *Florentina*, *Germanica*, and *Pseudacorus* are still used in medicine [h].

The root of *Iris Florentina* is extremely acrid, and when chewed excites a pungent heat in the mouth, which continues some hours: on being dried, this acrimony is almost wholly dissipated, the taste being slightly bitter, and the smell agreeable, and approaching to that of Violets. No essential oil has hitherto been obtained from this root, but spirituous tinctures of it contain more of its virtues than watery infusions. The fresh root is a powerful cathartic, and for this purpose its juice has been employed in the dose of a dram and upwards in dropsies. It is now chiefly used in its dried state, and ranked as a pectoral, or expectorant, and hence has a place in the Trochisci amyli of the Lond. Pharm. We have however no evidence of its expectorant powers, and therefore must consider it as valuable only for the pleasantness of its perfume, and the flavour which it communicates.

The root of *Iris Pseudacorus* or Common Yellow Water-Flag had formerly a place in the London Pharm. under the name of Gladiolus luteus. It has an acrid burning taste, and the juice on being snuffed up the nostrils produces a great heat in the mouth and nose, accompanied by a copious discharge from these organs: hence it is recommended as a sialogogue and an errhine. The root is such a powerful astringent, that it has been used instead of galls in making ink, and also for the purpose of dying black: and from the same quality, it has also been used successfully in diarrhœas: when given with this intention, the root should be well dried; the fresh root and its juice being so strong a cathartic that eighty drops of the latter produced repeated evacuations after jalap, gamboge, &c. had failed: this dose was given every hour or two in a little syrup of buckthorn, and had very immediate effects; causing the patient to discharge by stool several Scots pints of water in the course of the night. By continuing its use in an increased dose it cured an inveterate dropsy. Hence Bergius says "Virtus *recent.* hydragoga, purgans; *siccat.* adstringens." The expressed juice is likewise said to be an useful application to serpiginous eruptions and scrophulous tumours [i].

The *Iris Germanica* or Common blue Flower de Luce possesses similar qualities; the fresh roots being a strong irritating cathartic: in this intention their fresh juice may be given in hydropic cases in doses of one or two drams to three or four ounces, diluted largely with watery or vinous liquors, to prevent its inflaming the throat. The remarkable differences in the dose, as directed by different practitioners, appear to arise

[a] Thunberg. [b] Ibid. [c] Ibid. [d] Ibid. [e] Hort. kew. [f] Thunb. in Linn. transf. [g] Thunb. dis. [h] Woodv.

from this circumſtance; viz. that ſome have employed the juice in its recent turbid ſtate, loaded with the acrimonious cathartic matter of the root, while others uſed ſuch as had been depurated by ſettling, and which had depoſited its more active and acrimonious parts[1].

The root of the Flower de Luce ſuſpended in wine or beer keeps the latter from growing ſtale, and communicates a pleaſant taſte and ſmell to the former. The juice is alſo ſometimes made uſe of as a coſmatic, and for removing freckles.

A moſt beautiful paint or colour is prepared from the flowers in the following manner; viz. the flowers are collected before they are fully expanded, and are to be bruiſed in a ſtone mortar with a wooden peſtle: then put into a glaſs, and placed for ſome days in a cellar or other moiſt place: after the ſpace of about a fortnight the maſs, which is now become liquid, is to be ſet over the fire in a glaſs pot, till about a third part is conſumed; then ſome roche alum is to be put into it, more or leſs, till it becomes clear, and acquires its fine blue colour; after which it is poured into ſhells for uſe, as a water colour.

Iris foetidiſſima or Stinking Gladdon. The country people in ſome parts of England are ſaid to purge themſelves with the decoction of this plant. Thoſe who would not have it work too ſtrongly, make an infuſion of the ſliced roots in ale; and ſome take the leaves, which are more convenient for tender ſtomachs. The juice of the root has alſo been uſed as an emmenagogue as well as for cleanſing eruptions of various kinds.]

PROPAGATION AND CULTURE.

All the hardy ſorts of Iris are generally propagated by parting their roots, which moſt of them multiply faſt enough. The beſt time to remove and part the roots is in autumn, that they may get good root before the ſpring, otherwiſe they will not flower ſtrong the following ſummer. All thoſe ſorts which ſpread much at their roots ſhould be tranſplanted every other year, to keep them within bounds, otherwiſe they will ſpread ſo much as to become troubleſome, eſpecially if they are planted near other flowers; indeed, the large growing kinds are moſt of them too ſpreading for the flower-garden, ſo are only fit to fill up the ſpaces between trees and ſhrubs in large plantations, where they will have a good effect during the time of their flowering.

The third, fourth, ſixth, twenty-third, twenty-fourth, thirty-fourth, thirty-ſixth, and ſome others grow in leſs compaſs, ſo may be admitted into the large borders, or in clumps of flowers in the pleaſure-garden, where they will add to the variety. The fourth ſort ſhould have a warm ſituation, being a little tender, but all the other ſorts will grow in almoſt any ſoil or ſituation; theſe may all be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, then the plants will come up the following ſpring; but if the ſeeds are ſown in the ſpring, they will lie a year in the ground before they vegetate: when the plants come up they muſt be kept clean from weeds, and the following autumn ſhould be tranſplanted into beds at ten inches or a foot diſtance, where they may remain till they flower, which will be the ſecond ſummer after tranſplanting; but as moſt of the ſorts are ſo eaſily propagated by their roots, few people care to wait for ſeedling plants, unleſs of thoſe ſorts which are ſcarce.

[4. The Chalcedonian Iris flowers well in favourable ſituations, but ſucceeds beſt in a loamy ſoil and ſunny expoſure, with a pure air: moiſture, which favours the growth of moſt of the genus, is injurious, and ſometimes even fatal to this ſpecies. As it rarely ripens ſeeds with us, it is generally increaſed by the roots. Being liable to be deſtroyed by ſeaſons unuſually ſevere, it will be prudent to place a few roots of it in pots, either in a green-houſe or hot-bed frame during the winter: or it may be had of the importers of bulbs from Holland at a reaſonable rate. It bears forcing well[2].]

[1] Lewis. [2] Curtis.

19, 30. Xiphium or Bulbous Iris and Perſian Iiris are alſo propagated by offſets from the roots. The bulbs of the former need not be taken up oftener than every other year, and of the latter every third year: this ſhould be done ſoon after the leaves decay, otherwiſe they will ſend out freſh fibres: nor ſhould they be kept above a month out of the ground, becauſe they will ſhrink, and flower weakly the following year.

They may alſo be propagated by ſeed in the ſame manner as the HYACINTH: and this is the only way to obtain varieties of the Xiphium. The Perſian Iris does not vary even from ſeeds.

Theſe flowers thrive beſt in a light ſandy loam; and if it be taken from a paſture ground with the ſward, laid in a heap to rot, it will be ſtill better; for theſe bulbs do not delight in a rich dunged ſoil: nor ſhould they be too much expoſed to the ſun, but in an eaſt border, they will thrive and flower extremely well.

In propagating the Perſian Iris from ſeed, the boxes in which the ſeeds are ſown, ſhould be put under a garden frame in winter, to ſhelter them from hard froſt.

47. The Snake's-head Iris is propagated by the roots, which ſend out offſets; theſe may be taken up and tranſplanted when their leaves decay, but ſhould not be kept too long out of the ground. If theſe are planted in a deep looſe ſoil, the roots will run down, and be loſt in a few years where they are not diſturbed, ſo they ſhould be annually tranſplanted, and have a ſhallow ſoil: they are hardy in reſpect to cold, and require no farther care but to keep them clean from weeds.

They flower beſt when planted to an eaſt aſpect. If they are to be increaſed they ſhould not be removed oftener than once in three years. The diſtance which they ſhould be allowed is ſix inches ſquare, and they ſhould be planted three inches deep in the ground. As the multiply pretty faſt by the roots few perſons raiſe them from ſeeds. This however may be done in the way directed for the Bulbous Iris and Hyacinth. In light land it will be proper to lay rubbiſh in the bottom of the border where the Iris is planted, to prevent the roots from running deep into the ground; in which caſe they ſeldom produce flowers.

[The Cape Iriſes muſt be kept in the dry ſtove; and increaſed and managed in the ſame manner as other Cape bulbs.

DESCRIPTIONS, *&c.*

1. Our common Woad is a biennial plant, with a fuſiform, fibroſe root. Stem upright, round, ſmooth, woody at bottom, branched at top. Root-leaves ovate-lanceolate, on long footſtalks, down which they run a little. Stem-leaves alternate, quite entire, embracing, ſmooth, from two to three inches long, and ſcarcely half an inch in breadth. Theſe are ſometimes very ſlightly toothletted: and a few hairs are ſometimes found both on the ſtem and leaves. Flowers ſmall, terminating the ſtem and branches in a cloſe raceme. Both corolla and calyx yellow: petals notched at the end. Seed-veſſels on ſlender peduncles, handing down, cheſtnut-coloured or dark brown and ſhining when ripe, of an oblong elliptic form, near half an inch long and two lines wide, compreſſed at top and on the ſides into a ſharp edge, ſwelling like a convex lens in the middle, with a ſtraight longitudinal ſuture on each ſide, one-celled, two-valved, but hardly opening ſpontaneouſly: valves of ſpongy ſubſtance like cork, and boat-ſhaped. Seed ſmooth, ſtriated a little, two lines long, and three quarters of a line wide, yellow or brownith yellow when ripe: it has only a ſingle membranaceous coat. Embryo curved, yellowiſh. Cotyledons ovate, fleſhy, plano-convex. Radicle ſubcylindrical, bent in upwards, lying on the back, not on the cleft of the cotyledons, ſuperior [a].

Gærtner remarks, that the ſituation of the radicle in the *ſiliculoſæ* is various: being centrifugal in all thoſe which contain ſeveral ſeeds; generally ſuperior in one-ſeeded ſilicles; ſeldom centripetal; and in Cakile alone inferior.]

Mr. Miller thus deſcribes the cultivated plant, which however differs little from the wild one except in luxuriance. The lower leaves are of an oblong oval figure, and pretty thick conſiſtence, when growing in a proper ſoil; they are narrower at their baſe, but broad above, and end in obtuſe roundiſh points; are entire on their edges, and of a lucid green. The ſtalks riſe near four feet high, dividing into ſeveral branches, with arrow-ſhaped leaves, ſitting cloſe: the ends of the branches are terminated by ſmall yellow flowers, in very cloſe cluſters. The pods are ſhaped like a bird's tongue, half an inch long, and one-eighth of an inch broad, turning black when ripe. It flowers in july, and the ſeeds ripen the beginning of ſeptember.

Mr. Miller has another ſpecies, which he names

[a] Pollich, Gærtner, Engl. bot. Withering.

I. dalmatica or Dalmatian Woad, from the place of its growth. The lower leaves of this are ſpear-ſhaped and crenated; thoſe on the ſtalk very narrow and arrow-pointed. The ſtalks branch more than thoſe of the firſt ſort, and riſe higher. The flowers are larger, and of a brighter yellow colour. The ſeed-veſſels are ſhorter, and broader at the ends, which are indented. [It is probably a variety of the common Woad, but no ſpecimen of it occuring in Mr. Miller's herbarium, we cannot ſpeak of it with certainty.

Dyer's Woad is a native of ſeveral parts of Europe, as on the coaſt of the Baltic and Ocean, by way-ſides in Switzerland, &c. [b] In England, in corn-fields and on the borders of them, as at New Barns near Ely, by the river Wear near Durham, &c. This makes us ſuſpect that Woad is not an aboriginal with us, but has been naturaliſed by its frequent culture for dying; for, according to Linneus at leaſt, it is a maritime plant. Yet if the plant which Pliny informs us the ancient Britons painted their bodies with be ours, which is very probable, it muſt be a native [c].

Woad is much uſed by dyers for its blue colour, and it is the baſis of black and many other colours.

Queen Eliſabeth, as Hume words it, took offence at the ſmell of this herb, and iſſued an edict prohibiting any one to cultivate it [d].

According to Hakluyt, we were dependent upon France for it in 1576 [e]. But in 1582 he ſays, "thus "was Woad brought in, and came to good perfec-"tion, to the great loſs of the French, our old ene-"mies [f]."

2. According to Linneus this is ſcarcely different from the preceding, only it is annual and ſmaller. Gmelin ſays the flowers are white.] Mr. Miller affirms, that there are very eſſential differences between them, particularly in the ſhape of the under leaves, which in this are narrow and ſpear-ſhaped, and thoſe on the ſtalks are not more than half the breadth of thoſe on the cultivated Woad. The ſtalks do not branch ſo much, and the pods are narrower, nor do the roots abide ſo long, for they generally die within the year. [Native of Portugal and the Levant. Cultivated by Mr. Miller in 1739 [g].

3. Stem a foot high, loaded with yellow flowers.—Native of Armenia in dry paſtures, by the ſides of brooks [h].]

4. An annual plant, and a native of Egypt.

[5. Stem half a yard high, dividing into two, three or four ſhort branches, ſupported by ſhort leaves. Flowers in a ſort of umbel, in ſhort racemes, yellow, on yellow filiform peduncles. The calyx is alſo yellow. Corolla ſpreading very much, with the petals twice as long as the calyx, oblong-cordate, with linear claws. Filaments and anthers yellow; the latter ſagittate. The flowers have hardly any ſmell. Siliclc not wedge-ſhaped, but ovate and larger, than that of I. tinctoria, from which it differs in having a perennial root, in the height of the whole plant, in the flowers being much larger, the ſiliclcs ſhort, ovate, and alſo much larger.

Native of the mountains of Piedmont [i].]

PROPAGATION AND CULTURE.

None of the ſorts are cultivated for uſe except the firſt, but are preſerved only in botanic gardens. The ſecond and fifth ſorts are propagated by ſeeds ſown in autumn, and when the plants come up they muſt be thinned, leaving them ſix inches apart, and kept clean from weeds: the ſummer following they will flower and produce ripe ſeeds, after which they ſoon decay.

3, 4. Theſe are too tender to thrive in the open air in England. Sow the ſeeds on a hot-bed in the ſpring, and when the plants are fit to remove, tranſplant them on a freſh hot-bed; as ſoon as they have taken new root give them a large ſhare of freſh air, to prevent their being drawn up weak. In this bed they may remain five or ſix weeks, by which time they will be fit to tranſplant into pots, which ſhould be plunged

[b] Linn. [c] Engl. bot.

into

into a moderate hot-bed, giving the plants plenty of air when the weather will permit, and ſupporting their ſtalks, which will otherwiſe trail on the ground: with this management the plants will flower in june, and ripen their ſeeds in ſeptember.

1. The firſt ſort which is propagated for uſe, is ſown upon freſh land which is in good heart, for which the cultivators of Woad pay a large rent; they generally chuſe to have their land ſituated near great towns, where there is plenty of dreſſing, but they never ſtay long on the ſame ſpot, for the beſt ground will not admit of being ſown with Woad more than twice; for if it is oftener repeated, the crop ſeldom pays the charges of culture, &c.

Thoſe who cultivate this commodity, have gangs of people who have been bred to this employment; ſo that whole families travel about from place to place, wherever their principal fixes on land for the purpoſe; but theſe people go on in one track, juſt as their predeceſſors taught them; nor have their principals deviated much from the practice of their anceſtors, ſo that there is a large field for improvement, if any of the cultivators of Woad were perſons of genius, and could be prevailed on to introduce the garden culture ſo far as it may be adapted to this plant; this I know from experience, having made numbers of trials in the culture of this plant, therefore I ſhall inſert them here for the benefit of thoſe who may have ingenuity enough to ſtrike out of the old beaten track.

As the goodneſs of Woad conſiſts in the ſize and fatneſs of the leaves, the only method to obtain this, is to ſow the ſeed upon ground at a proper ſeaſon, and allow the plants proper room to grow, as alſo to keep them clean from weeds; which, if permitted to grow, will rob the plants of their nouriſhment. The method practiſed by ſome of the moſt ſkilful kitchen-gardeners in the culture of Spinach, would be a great improvement to this plant, for ſome of them have improved the round-leaved Spinach, ſo much by culture, as to have the leaves more than ſix times the ſize they were formerly; and their fatneſs has been in the ſame proportion, upon the ſame land, which has been effected by thinning the plants when young, and keeping the ground conſtantly clean from weeds; but to return to the culture of Woad.

After having made choice of a proper ſpot of land, which ſhould not be too light and ſandy, nor over ſtiff and moiſt, but rather a gentle hazel loam, whoſe parts will eaſily ſeparate: the next is to plough this up juſt before winter, laying it in narrow high ridges, that the froſt may penetrate through the ridges, to mellow and ſoften the clods; then in the ſpring plough it again croſſways, laying it again in narrow ridges; after it has lain ſome time in this manner, and the weeds begin to grow, it ſhould be well harrowed to deſtroy them; this ſhould be twice repeated while the weeds are young, and if there are any roots of large perennial weeds, they muſt be harrowed out, and carried off the ground. In june the ground ſhould be a third time ploughed, when the furrows ſhould be narrow, and the ground ſtirred as deep as the plough will go, that the parts may be as well ſeparated as poſſible; and when the weeds appear again, the ground ſhould be well harrowed to deſtroy them. Towards the end of july, or the beginning of auguſt, it ſhould be ploughed the laſt time, when the land ſhould be laid ſmooth, and when there is a proſpect of ſhowers, the ground muſt be harrowed to receive the ſeeds, which ſhould be ſown either in rows with the drill plough, or in broad-caſt, after the common method; but it will be proper to ſteep the ſeeds one night in water before they are ſown, which will prepare them for vegetation: if the ſeeds are ſown in drills with a plough, they will be covered by an inſtrument fixed to the plough for that purpoſe; but thoſe which are ſown broad-caſt in the common way, muſt be well harrowed in. If the ſeeds are good, and the ſeaſon favourable, the plants will appear in a fortnight, and in a month or five weeks after will be fit to hoe; the ſooner this is performed when the plants are diſtinguiſhable, the better they will thrive, and the weeds being then young, will be ſoon deſtroyed. The method of hoeing theſe plants is the ſame as for Turneps, with this difference only, that theſe plants need not be thinned ſo much; for at the firſt hoeing, if they are ſeparated to the diſtance of three or four inches, and at the laſt to ſix inches, it will be ſpace enough for the growth of the plants; if this is carefully performed, and in dry weather, moſt of the weeds will be deſtroyed: but as ſome of them may eſcape in this operation, and young weeds will ariſe, the ground ſhould be a ſecond time hoed in october, always chuſing a dry time for this work; at this ſecond operation, the plants ſhould be ſingled out to the diſtance they are to remain. After this the ground will be clean from weeds till the ſpring, when young weeds will come up, therefore about a fortnight in april will be a good time to hoe the ground again, when the weeds will be young, and it may be performed in leſs than half the time it would require if the weeds were permitted to grow large, and the ſun and wind will much ſooner kill them, this hoeing will alſo ſtir the ſurface of the ground, and greatly promote the growth of the plants; if it is performed in dry weather, the ground will be clean till the firſt crop of Woad is gathered, after which it muſt be again well cleaned; if this is carefully repeated, after the gathering of each crop, the land will always lie clean, and the plants will thrive the better. The expence of the firſt hoeing will be about ſix ſhillings per acre; and for the after-hoeings half that price will be ſufficient, provided they are performed when the weeds are young; for if they are ſuffered to grow large, it will require more labour, nor can it be ſo well performed; therefore it is not only the beſt huſbandry to do this work ſoon, but it will be found the cheapeſt method; for the ſame number of men will hoe a field of ten acres three times, when it is performed while the weeds are young, as is required to hoe it twice only, becauſe the weeds have longer time to grow between the operations.

If the land in which the ſeed is ſown, ſhould have been in culture before for other crops, ſo not in good heart, it will require dreſſing before it is ſown, in which caſe rotten ſtable dung is preferable to any other; but this ſhould not be laid on till the laſt ploughing before the ſeeds are ſown, and not ſpread but as the land is ploughed, that the ſun may not exhale the goodneſs of it, which in ſummer is ſoon loſt, when ſpread on the ground. The quantity ſhould not be leſs than twenty loads to each acre, which will keep the ground in heart till the crop of Woad is ſpent.

The time for gathering the crop is according to the ſeaſon, but it ſhould be performed as ſoon as the leaves are fully grown, while they are perfectly green; for when they begin to change pale, great part of their goodneſs is over; for the quantity, will be leſs, and the quality greatly diminiſhed.

If the land is good, and the crop well huſbanded, it will produce three or four gatherings, but the two firſt are the beſt; theſe are commonly mixed together in the manufacturing of it, but the after crops are always kept ſeparate; for if theſe are mixed with the other, the whole will be of little value. The two firſt crops will ſell from twenty-five to thirty pounds a ton; but the latter will not bring more than ſeven or eight pounds, and ſometimes not ſo much. An acre of land will produce a ton of Woad, and in good ſeaſons near a ton and a half.

When the planters intend to ſave the ſeeds they cut three crops of the leaves, and then let the plants ſtand till the next year for ſeed; but if only one crop is cut, and that only of the outer leaves, letting all the middle leaves ſtand to nouriſh the ſtalks, the plants will grow ſtronger, and produce a much greater quantity of ſeeds.

Theſe ſeeds are often kept two years, but it is always beſt to ſow new ſeeds when they can be obtained. The ſeeds ripen in auguſt; when the pods turn to a dark colour, the ſeeds ſhould be gathered; it is beſt done by reaping the ſtalks in the ſame manner as Wheat, ſpreading the ſtalks in rows upon the ground, and in four or five days the ſeeds will be fit to threſh out, provided the weather is dry; for if it lies long the pods will open and let out the ſeeds.

Some of the Woad planters feed down the leaves in winter with ſheep, which is a very bad method; for all plants which are to remain for a future crop, ſhould never be eaten by cattle, for that greatly weakens the plants.

ISATIS INDICA. See *Indigofera tinctoria.*

ISCHÆMUM. (*From* ἰσχω *reprimo, and* αιμα *ſanguis, on account of its virtue in ſtopping hæmorrhages.*)

Lin. gen. n. 1148. *Reich.* 1254. *Schreb.* 1569. *Juſſ.* 30.

Claſſ. 23. 1. Polygamia Monoecia.

Nat. order of *Gramina, Graminæ* (Juſſ.) or *Graſſes.*

GENERIC CHARACTER.

CAL. *Glume* two-flowered, bivalve, cartilaginous, placed tranſverſely: *Valves* nearly equal: the *exterior* ſubovate, gibboſe, with biſid tip, ſharp, the upper part of the back flat in the middle, ſtriated, emarginated; the *interior* oblong, acuminate or awned at the tip, the back beneath the tip increaſed by a longitudinal membrane.

Floſcule exterior male, interior hermaphrodite; each leſs than the calyx.

COR. In the hermaphrodite a bivalve *glume*; *valves* membranaceous, thin, colourleſs; the *exterior* bellied, either mutic or awned, biſid to the very awn, acute: *awn* long, ſlender, jointed, tortile beneath; the interior lanceolate, acute, conduplicate at the edges.

In the male a bivalve *glume*, rather firmer, diaphanous, rather coloured; the *exterior* oblong, bellied, contracted above, ſharp, mutic; the *interior* oblong, obtuſe, with concave back, acutely margined, margin thinner.

Nectary in each two-leaved: *leaflets* ſmall, ſpatulate, truncate-emarginate.

STAM. *Filaments* three, capillary, ſhort. *Anthers* oblong, biſid on both ſides.

PIST. In the hermaphrodite, *Germ* oblong. *Styles* two, capillary, erect, ſhorter than the corolla. *Stigmas* oblong, plumoſe, ſpreading, exſerted.

PER. none. Calyx and corolla unchanged.

SEED (in the hermaphrodite) ſingle, oblong, linear, convex on one ſide.

OBS. *The flowers are ſpicated, and grow double: the one ſubſeſſile, the other ſeated on a broad glumaceous foot-ſtalk; each hermaphrodite.* S.

ESSENTIAL CHARACTER.

HERM. *Cal.* Glume two-flowered. *Cor.* two-valved. *Stam.* three. *Styles* three. *Seed* one.

MALE. *Cal.* and *Cor.* as in the other. *Stam* three.

SPECIES.

Tagadi. *Rheed. mal.* 12. 91. *t.* 49.
Leaves lanceolate, flowers awnleſs.

2. Iſchæmum ariſtatum.
Lin. ſpec. 1487. *Reich.* 4. 312.
I. ciliare. *Retz. obſ.* 6. 36. *n.* 78.
Leaves lanceolate, calyxes two-flowered, pedicels ciliate, each female flower with a twiſted knee-jointed awn.

3. Iſchæmum imberbe.
Retz. obſ. 6. 35. *n.* 76.
Leaves lanceolate, florets naked, outer valve of the ſeſſile calyx having two knobs on each ſide, and the corolla elongated by a twiſted awn.

4. Iſchæmum barbatum.
Retz. obſ. 6. 35. *n.* 77.
Leaves lanceolate, calyxes two-flowered, bearded at the baſe, and ciliate at the edge, the edge of the ſeſſile one with two knobs on each ſide, awn twiſted, knee-jointed.

5. Iſchæmum murinum.
Forſt. fl. auſtral. n. 384. *nov. act. upſ.* 3. 185.
Spike two-parted, calyx and ſeeds awned.

6. Iſchæmum involutum.
Forſt. fl. auſtral. n. 385.
Spike directed one way, awnleſs, four-flowered, involved in a leafy concave receptacle.

7. Iſchæmum importunum.
Lour. cochinch. 646.
Panicle contracted, corollas one-valved.

8. Iſchæmum rugoſum.
Saliſb. ic. t. 1.
Outer barren glumes tranſverſely wrinkled, male and female florets fertile one only awned.

DESCRIPTIONS, &c.

1. Spike two-parted, imbricated, with alternate, ſimple, two-flowered, angular peduncles, preſſed cloſe to the culm. One flower terminates each peduncle, which is hermaphrodite, from a two-glumed one-flowered calyx: the ſecond or lower flower is androgynous, ſeſſile and inſerted into each peduncle at the outer baſe, from a two valved hardiſh calyx, the length of the florets, of which it contains two, one male, the other female. Stigmas thick, bearded. Peduncle of the ſpike cloathed with leaves [a].

Culms a foot or eighteen inches high, leafy to the very ſpike, frequently branched to the baſe. Leaves two inches long, ciliate-ſpinuloſe on the edges. Spikes two, terminating, joined ſo as to appear one, or one divided to the baſe. Calyxes in pairs, cartilaginous; one ſeſſile, two-flowered, androgynous; the other pedunculed, male or neuter, one-flowered. The outer glume of the firſt ovate, flattiſh, ſpread out at the edge, biſid at the tip, the inner edge bent in: the inner glume equal in ſize, mucronate at the tip, the edge of one ſide only bent in. Outer corolla male, with one edge of the outer valve bent in, the other flat; but the inner valve has both edges bent in: inner corolla female, with the outer valve awnleſs; the inner ending in a ſhort awn-ſhaped dagger-point, with both edges bent in. Stigmas two, thick, feathered, yellow; all the corolline glumes hyaline.—The ſecond flower lateral, neuter or ſometimes male, on a three-ſided pedicel. Calycine valves three-ſided and compreſſed. One glume of the corolla ſhortly awned [b].

Native of the Eaſt Indies, and of the iſle of Tanna.

2. The ſtructure of the ſpike and of the flowers is entirely the ſame as in the preceding, but the culm is higher, the ſpike longer, and the peduncle naked. The ſeeds are armed with a twiſted awn, longer than the florets [c].

It is thus deſcribed by Retzius, under the name of *I. ciliare.*—Culm a foot and half high, branched, decumbent and rooting, with hairy joints. Leaves ſhort, with the ſheaths hairy at the edge. Peduncle naked. Spikes in pairs, an inch and half long, narrow, awned. Calyxes in pairs, two-flowered: one flower ſeſſile; the outer glume cartilaginous, ovate, ſwelling, ſtriated, both edges bent in; inner lanceolate, keeled; outer flower male, awnleſs, inner female awned, the awn having a long twiſted knee-joint: the other flower pedunculed, the peduncle three-ſided, ciliated at the corners and on the upper edge; both glumes cartilaginous, keeled, ſharp; one flower male, awnleſs, the other female and awned; the awn in both female flowers iſſues from the back of the corolla, which is cloven to the very baſe of the awn.

Native of China, where it was found by Oſbeck [d].

3. Culms two feet high, leafy, ſomewhat branched. Leaves like thoſe of the firſt ſort, but longer. Spike alſo like that, but awned and without hairs. Calyxes in pairs; one ſeſſile, two-flowered, the other pedunculed, one-flowered, neuter. In the firſt, the outer valve is cartilaginous, flattiſh, lanceolate, with two knobs on each ſide, and both edges bent in; the inner membranaceous, acute, one edge ſpread out flat, the other bent in; outer corolla neuter? awnleſs, inner hermaphrodite, with an elongated twiſted awn without any joint. In the ſecond floret the outer valve is cartilaginous, lanceolate, with one edge bent in, the other flat; inner equal in length, acute, membranaceous, with both edges bent in; corolline glumes hyaline ruſeſcent [e].

Native of the Eaſt Indies.

4. Culm and leaves as in the preceding, only the latter ſhorter. Spike longer, two-parted, awned, with the teeth of the rachis ciliate-bearded. Calyxes in pairs, each androgynous and two-flowered: one floret ſeſſile, the outer valve cartilaginous, bearded at the baſe, having two or three little knobs on each ſide, lanceolate, bent in on both ſides; the inner valve keeled, ſharp, ciliated along both edges; florets two, the outer male, the inner female and awned, awn bent

[a] Linn. ſpec. [b] Retzius. [c] Linn. ſpec. [d] Ibid. [e] Retzius.

as if broken, brown at the base, the rest white; glumes of the corolla hyaline, white, acute: the other floret pedunculed; outer valve half-ovate, cartilaginous, naked, inner lanceolate, acute; flowers two, outer male, inner female or neuter, both awnless, glumes of the corolla as in the others. Native of Java, where it was found by Wennerberg[f].

5. Culms filiform, slender, simple, a long span in height. Leaves linear, acuminate, flattish, striated, dry, a span long. Sheaths thin, lax, with the little membrane very short, and having hairs placed on it. Peduncle filiform, upright, frequently naked. Spike closely converging, cylindrical, two inches long, resembling that of Hordeum murinum. Florets on one side, distich, in pairs, one sessile, the other pedicelled, minute, being scarcely a line in length besides the awns. Valves of the calyx almost equal; outer oblong-lanceolate, striated, flattish, one edge bent in and keeled, embracing the inner valve, having two awns at the tip, or solitary, terminated by little granules: inner valve more slender, with a longer awn: base of the glumes hairy. Valves of the corolla awnless, oblong, hyaline, less than those of the calyx. A minute membrane invests the germ, having a flexuose awn four times as long as the floret, which may be considered as the nectary.

Native of the isle of Tanna, on dry sand, near the coast[g].

6. Native of the Society isles, and elsewhere between the Tropics[h]. Found in the island of Otaheite may 13th, 1774[i].

7. Root perennial, simple, long, jointed, white, very tough. Culm three feet high, almost upright, round, hollow, thickish. Leaves awl-shaped, short. Flowers ovate, smooth, awnless, small. Calycine glume two-valved, two-flowered, one flower hermaphrodite, the other male. Corolla one-valved, embracing each flower. Seed awnless.

Native of Cochinchina, where it is a common weed, not easily eradicated[k].

8. Root annual. Plant from seven inches to a foot in height. Stems pale green, slender, decumbent, bent back, branched dichotomously, round, little jointed, smooth, striated, somewhat rigid. Leaves pale green, dense, except one or two of the upper ones, which are more remote. Spike terminating, dense, two-parted. Some of the flowers at the base of each flexure of the peduncle are fertile, others at the ends of the branchlets are abortive. Glumes six, upright: two opposite, equitant, barren; and four within these, much less, and fertile: in the abortive flowers they are smaller.

Native of the East Indies, and found by Koenig in Orissa, on the borders of the Rice-fields[l].

Cultivated by Richard Antony Salisbury, Esq. at Chapel-Allerton, before 1791.

ISCHÆMUM. See *Andropogon* & *Panicum*.

ISERTIA. (*From M. Isert, a German, in the Danish service, as a Surgeon, on the coast of Guinea.*)

SPECIES.

Isertia coccinea.

Lin. syst. ed. Gmel. 567.

Guettarda coccinea. *Aubl. guian.* 317. *t.* 123.

DESCRIPTION, &c.

This is a tree with a trunk ten or twelve feet in height, and about eight inches in diameter; the bark wrinkled, and of a russet colour, the wood light, and of a loose texture. Branches quadrangular, straight, with opposite branchlets, channelled and covered with a russet down; at their origin are two embracing stipules. Leaves opposite, disposed crosswise, smooth, entire, oval, ending in a long point, ash-coloured underneath, with russet-coloured nerves; the largest fourteen inches long, and seven wide: petiole cylindric, channelled, two inches long, swelling at the base, with two wide, sharp, deciduous stipules. Flowers terminating, in a large, straight panicle, the branches of which are opposite and subdivided, and come out from between two little scales. Each branchlet has three flowers, of which that in the middle is sessile. Calyx purplish, that part which borders the germ yellow. Tube of the corolla two inches long, bright red. Border yellow, covered on the inside with hairs of the same colour. Fruit a succulent red berry (or pome), the size of a Cherry, sweet and good to eat.

The wood is bitter. A decoction of the leaves is used by the Creoles in fomentations.

It is common in the island of Cayenne, and on the Continent of Guiana, flowering and bearing fruit great part of the year[a].

ISNARDIA. (*So named by Linnæus, in memory of Monf. Antoine Dauti d'Isnard, member of the Academy of Sciences, and who published descriptions of some plants in their memoirs for* 1716, &c.)

Alsine palustris rotundifolia repens, foliis portulacæ pinguibus. *Lind. alsat. t.* 2. *f.* 6.

DESCRIPTION, &c.

This bears a great resemblance to Peplis Portulaca. It is creeping and floating. The flowers are axillary, opposite, sessile and green[b].

It is native of Italy, France, Alsace, Ruffia, Jamaica and Virginia, in rivers, and is annual[c]. According to Allioni it is perennial.

Swartz has determined it to be a species of *Ludwigia*, frequent in the rivers of Jamaica, with petals to the flower, though fugacious. The plant without petals differs from this, just as in Ammannia.

Leaves filiform, erect, smooth.

DESCRIPTIONS, *&c.*

1. Root fibrous; fibres numerous, simple, slender, striking deep into the mud. Leaves in thick tufts (eight or ten), from three or four to six or seven inches in length, extremely like young rushes, convex on the back, flat or slightly convex in front, at the base swelling into a kind of bulb, covered by a thin tender skin, which bursts and discovers itself to be filled with numerous minute whitish seeds, that appear spherical when examined in the microscope, roughish, somewhat transparent, and having three ribs meeting in a centre [a]. The leaves are so brittle, that they break on the least attempt to bend them [b]. Each leaf consists of several slender tubes, imbedded in a soft spongy substance, and furnished with transverse diaphragms that are very visible. When newly taken out of the water it is pellucid. The edges of the inflated base of the outer leaves, where the female flowers reside, form a thin fine membrane, which so closely embraces the gibbous part of the inner leaf, where the male flower is found, as to exclude the water. And by this admirable contrivance, the flowers of each sex are not only near each other, but though at the bottom of a lake are kept perfectly dry. After the discharge of the seeds the outer leaves fall off and perish, and the next in order perform the same office a succeeding year; and the number of leaves is kept up by a supply of young ones from the centre [c].

Native of mountain lakes, in the north of Europe. Westmoreland. Cumberland. Wales and Scotland. Flowering from may to september.

2. This resembles the preceding very much, but is larger. The bulb consists of the membranaceous dilated bases of the petioles. The leaves are near a foot long, filiform, not semicylindric.

Native of Coromandel, in wet places that are inundated in the rainy season. *Koenig* [a].

ISOPHYLLUM. See *Bupleurum*.

DESCRIPTIONS, *&c.*

1. This is an annual plant, seldom more than three or four inches high. The leaves, which are shaped like those of Fumitory, are small, and of a gray colour. The stalk is naked to the top, where there is a circle of leaves just under the flowers. The flowers are small, of an herbaceous colour on the outside, but yellow within. [Capsules ten to fifteen, leguminose, compressed a little, setaceous-beaked, curved a little inwards, veined, pale, thin, opening inwards. Seeds fixed in a double row to the edge of the opening suture, small, ovate-globular, covered with little raised dots, blackish, marked on one side with a linear hilum or scar [a].] Native of Siberia, whence the seeds were sent to the imperial garden at Petersburgh, and Dr. Ammann sent a part of the seeds to Mr. Miller, [who cultivated them at Chelsea in 1759 [b].] It flowers at the beginning of april (june, H. K.), and the seeds ripen in may.

2. [All parts of this plant are smooth, except the lower part of the stem and radical leaf, which is a little villose. Root perennial, creeping horizontally.

[a] Woodw. Mſs. [b] Withering. [c] Bolton.

[a] Linn. suppl. [a] Gærtn. [b] Hort. kew.

tally. Root-leaf one, seldom two, tender, shorter than the stem, on a long upright petiole, twice trifid; leaflets blunt, widening towards the end, two-lobed or three-lobed, netted-veined, ash-coloured, resembling the leaves of Thalictrum minus or bulbous Fumitory. Stem commonly single, from six inches to near a foot in height, simple or very seldom branched, naked below; but having a leaf or two towards the top, like the root-leaf, only less compound; the upper leaves are ternate or lobed. All the leaves have a pale roundish stipule on each side. The stem terminates in a few spreading slender peduncles, each bearing one small flower; the petals of which are at first white, but turn red or purple, the natural number is five, but there are sometimes six. Stamens from thirty to thirty-six; filaments a little thickened at the top; anthers upright. Germs one, two, or three, seldom four; becoming smooth, broad-oblong capsules, flatted a little, acuminated by the style from the inner suture, but opening by the upper, in this state spreading very wide open, keeled and concave, displaying two or three seeds.—The leaflets of the nectary are inserted into the receptacle before the petals, but not always in a regular order, they are shorter than the stamens by half or two thirds, are upright, ovate, white, concave, from a pedicelled base widening into a cowl, but quite entire[a].

Native of the South of Europe.] Mr. Miller had it from the neighbourhood of Verona, and cultivated it in 1759. It flowers at the end of march, and the seeds ripen in may. [According to Jacquin it flowers in Austria in april or the beginning of may.]

3. This has leaves like the second, but a little larger, and of a greener colour. The stalks rise about six inches high, supporting two or three small white flowers, shaped like those of the preceding. It flowers in april, and the seeds ripen in june.

[According to Caspar Bauhin, and Haller, and Kroeker from him, it differs from the preceding in having a very small root; the stem a long span in height, slender, having two or three, short, entire, stipular leaves on it, the rest like those of Thalictrum minus, only smaller; and a single blue flower, five times less than that of the preceding.

Native of the mountains of Switzerland, Moravia, Trent, and the Apennines, in meadows, flowering in the spring.

It is the same with Aquilegia viscosa of Linneus.]

ROPAGATION AND CULTURE.

Sow the seeds in a shady border soon after they are ripe, or permit them to scatter; and when they come up keep them clean from weeds. These plants delight in a shady situation.

DESCRIPTIONS, *&c.*

1. This is a shrub six or seven feet high, sending out many branches from bottom to top. Leaves alternate, slightly serrate, reflex, veined, light green. At the extremity of the same year's shoots, in the month of july, are produced fine spikes of white flowers, three or four inches long, and erect. When this shrub is in vigour, it is entirely covered with these flowers, and then makes a fine appearance.

[Linneus remarks, that the Itea has the appearance of the Padus; that the leaves are petioled, and the flowers in terminating racemes. The stigma is headed in this species, whereas in the next it is bifid or double[a].

Native of North America. Cultivated in 1744, by Archibald Duke of Argyle[b].

2. This is also a shrub three feet in height. Stem upright somewhat branched, round, ash-coloured: branches alternate or scattered, spreading, angular, rufous, smooth. Leaves alternate, bluntish, revolute with the edges a little waved, one-nerved; the midrib marked with lines above, prominent underneath, smooth, paler underneath, dry, spreading, flat, permanent, three inches long and an inch wide. Petioles very short, cylindric below, flat above, reddish. Racemes very many, lateral at the base of the new shoots, one from each bud, on short peduncles, spreading, from four to six inches long. Flowers scattered pedicelled, spreading, white, two or three lines in diameter. Bractæ linear, very sharp, white, withering, under the pedicels, than which it is scarcely longer. Bracteole two-leaved, opposite, linear, sharp, pressed close, on the pedicel itself next the calyx; which is white. Petals longer than the calyx. Anthers two-celled, peltate, very pale violet. Germ whitish: style short, compressed, scarcely bifid, shorter than the stamens: stigmas headed. Capsule sitting on the calyx, resembling two united styles by means of its double partitions.

The conformity of the flower and two-celled fruit persuade us to unite these two species under one genus[c].

Native of Carolina and Jamaica. It was observed in the former by Dr. Garden, in the latter by Swartz. Introduced here in 1765, by Mr. John Cree. It flowers in july and august[d].]

PROPAGATION AND CULTURE.

1. This shrub will live in the open air in England, but will not thrive upon dry gravelly ground. It is propagated by layers, which, if laid down in the autumn, will put out roots so as to be fit to remove by the following autumn, when they may be transplanted into a nursery, or to the place where they are to remain.

[2. This requires the protection of the greenhouse: and may be increased by layers or cuttings.

DESCRIPTIONS, *&c.*

1. This is an annual plant, with an herbaceous ſtalk, riſing from two to three feet high, ſending out ſeveral branches from the ſides. The leaves have three deep longitudinal veins and are ſerrate. The ſtalks and branches are terminated by ſmall cluſters of pale blue flowers, which appear in july, and the ſeeds ripen in autumn.

[Calyx globular, five-leaved, ſeldom three-leaved or four-leaved. Chaffs of the receptacle linear, longer than the androgynous flowers. Female corollets crenulate, not diſtinctly and regularly cut into teeth. Seeds (to the females) obcordate, angular*.

Native of South America, in many parts of the Weſt Indies. Cultivated, by Mr. Miller in 1768.]

2. This has ſlender woody branches, eight or ten feet high. Leaves ſerrate. Branches terminated by ſmall cluſters of pale purple flowers. [Receptacle flattiſh, with linear, diſtant chaffs, almoſt equal to the calyx. Seeds (in the female corollets) obovate, acuminate downwards, ſlightly convex on one ſide, angular or three-ſided on the other, pale ſtraw-coloured, ſmooth, bald†.

Native of Virginia and Peru. Cultivated in 1711 by the Dutcheſs of Beaufort. It flowers in auguſt‡.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds on a moderate hot-bed, and when the plants are fit to remove tranſplant them to another hot-bed, treating them as is directed for IMPATIENS.

2. This ſhrub was preſerved in the green-houſe, but ordinary winters in England ſeldom hurt it, provided it is planted in a dry ſoil and a ſheltered ſituation. If the branches be layed in the ſprings they will put out roots in ſix months; or if cuttings be planted in a ſhady border in may, they will take root.

Leaflets in threes.

DESCRIPTIONS, *&c.*

1. The Walnut is a very large and lofty tree, with ſtrong ſpreading boughs. Leaves pinnate, with a very ſtrong but not unpleaſant ſmell: Leaflets three pairs (ſometimes two or four), nearly equal, except that the odd one is larger, they are entire, ſmooth, and ſhining. Male flowers in cloſe, pendulous, ſubterminating aments. Females ſcattered, frequently two or three together. Fruit an ovate, coriaceous, ſmooth drupe incloſing an irregularly grooved nut, which contains a four-lobed, oily, eatable kernel, with an irregular knobbed ſurface, and covered with a yellow ſkin.

There are ſeveral varieties of the Common Walnut, which have been ſpecified above, but they all vary again when raiſed from the ſeed, and nuts from the ſame tree will produce different fruit; perſons therefore who plant the Walnut for its fruit, ſhould make choice of the trees in the nurſeries, when they have their fruit upon them.

The flowers begin to open about the middle of april, and are in full blow by the middle of may, before which time the leaves are fully diſplayed. Even in the South of France it is frequently injured by ſpring froſts; to avoid this, it is a practice in Switzerland to engraft the common ſtocks with the late-ripe variety, which does not produce its fruit before the month of may or june[a]. This might perhaps be too late for us, but in warmer climates, where the fruit is of much conſequence for the oil which it yields, where the Olive will not ſucceed, it may be worth attending to. In France, Switzerland, &c. the wood is in great requeſt for furniture, as it was formerly in England, till the uſe of Mahogany ſuperſeded it.

Were this timber, ſays Mr. Evelyn, in greater plenty amongſt us, we ſhould have far better utenſils of all ſorts for our houſes, as chairs, ſtools, bedſteads, tables, wainſcot, cabinets, &c. inſtead of the more vulgar Beech, ſubject to the worm, weak and unſightly; but which, to counterfeit and deceive the unwary, they waſh over with a decoction made of the green huſks of Walnuts, &c.

What univerſal uſe, he continues, the French make of the timber of this tree for domeſtic affairs, may be ſeen in every room both of poor and rich. It is of ſingular uſe with the joiner for the beſt grained and coloured wainſcot; with the gunſmith for ſtocks; with the coachmaker for wheels and the bodies of coaches; the cabinet-maker uſes it for inlayings, eſpecially the firm and cloſe timber about the root, which is admirable for flecked and cambleted works. To render this wood the better coloured joiners put the boards into an oven after the batch is forth, or lay them in a warm ſtable; and when they work it, poliſh it over with its own oil very hot, which makes it look black and ſleek, and the older it is, the more eſtimable; but then it ſhould not be put in work till thoroughly ſeaſoned, becauſe it will ſhrink beyond expectation. It is only not good to confide in it much for beams or joiſts, becauſe of its brittleneſs.

Beſides the uſes of the wood, the fruit, when tender and very young, is uſed for preſerves. It makes alſo food and oil: this laſt is of extraordinary uſe with the painter in whites and other delicate colours, alſo for gold ſize and varniſh; and with this they poliſh walking-ſtaves, and other works which are wrought in with burning. They fry with it in ſome places, and eat it in Berry inſtead of butter, of which they have little or none good; and therefore they plant infinite numbers of theſe trees all over that country: the uſe of it to burn in lamps is common there.

The very huſks and leaves being macerated in warm water, and that liquor poured on graſs-walks and bowling-greens, infallibly kills the worms, without endangering the graſs[b]. Not that there is any thing peculiarly noxious in this decoction, but worms cannot bear the application of any thing bitter to their bodies, which is the reaſon that bitters, ſuch as Gentian, are the beſt deſtroyers of worms lodged in the bowels of animals. Worms are ſeldom obſerved in the inteſtines of the human body, exceeping in caſes where the bile is either weak or deficient[c].

The dye made of this lixive will colour woods, hair and wool; and the green huſks boiled, make a good colour to dye a dark yellow, without any mixture.

The younger timber is held to make the better-coloured work; but the older, being more firm and cloſe, is finer cambleted for ornament. Thoſe trees which are raiſed from the thick-ſhelled fruit become the beſt timber; but the thin-ſhelled yield better fruit.

Thoſe nuts which come eaſily out of their huſks ſhould be laid to mellow in heaps, and the reſt expoſed in the ſun till the ſhells dry, elſe the kernels will be apt to periſh: ſome again preſerve them in their own leaves, or in a cheſt made of walnut-tree wood; others in ſand, eſpecially for a ſeminary. Old nuts are not wholeſome till macerated in warm water; but if you bury them in the earth in pots, out of the reach of the air, and ſo as no vermin can attack them, they will keep marvellouſly plump the whole year about, and may eaſily be blanched. *In Spain, they ſtrew the* gratings of old and hard nuts, firſt peeled, into their tarts and other meats. For the oil, one buſhel of nuts will yield fifteen pounds of peeled and clear kernels, and that half as much oil, which the ſooner it is drawn, is the more in quantity, though the drier the nut, the better in quality: the lees or marc of the preſſing is excellent to fatten hogs with. After the nuts are beaten down, the leaves ſhould be ſweeped into heaps, and carried away, becauſe their extreme bitterneſs impairs the ground[d].

The unripe fruit, ſuch as has been long uſed as a pickle, is directed for medicinal uſe by the London College, as an anthelmintic, and many authors ſpeak of its effects in deſtroying worms. An extract is the moſt convenient preparation, as it may be kept for a ſufficient length of time, and made agreeable to the ſtomach by mixing it with cinnamon water. In this ſtate the Walnut is ſaid alſo to be laxative, and of uſe in apthous affections and ſore throats: for this purpoſe a rob may be prepared from the juice. The vinegar in which Walnuts have been pickled is a very uſeful gargle. The kernel is ſimilar in qualities to the Almond; the oil does not congeal by cold, and anſwers the medicinal purpoſes of the oil of almonds[e].

We are not certain of the native place of growth of the Walnut-tree. It is not an aboriginal of Eu-

[a] Villars.

[e] Woodville.

rope,

rope, and there is little doubt but that it came into Italy from Greece, and into Greece from ſome part of Aſia. Some authors take it for the *Nux Perſica* of Theophraſtus; Pliny (l. 15. c. 24.) ſays, it was brought from Perſia by the kings; and on the authority of Lerche it is now ſet down as a native of Perſia in the later works of Linneus. According to Loureiro, it is found wild in the northern provinces of China.

It is much cultivated in ſome parts of Italy; France, Germany, and Switzerland. Burgundy, ſays Mr. Evelyn, abounds with Walnut-trees, where they ſtand in the midſt of goodly wheat-lands, at ſixty and a hundred feet diſtance, and ſo far are they from hurting the crop, that they are looked upon as great preſervers by keeping the ground warm, nor do the roots hinder the plough. Whenever they fell a tree, which is only the old and decayed, they always plant a young one near him. In ſeveral places betwixt Hanau and Frankfort in Germany, no young farmer is permitted to marry a wife, till he bring proof that he has planted a ſtated number of Walnut-trees. The Bergſtras, which extends from Heidelberg to Darmſtadt, is all planted with Walnuts[4]. According to Pallas, it is common in the Ukraine, the Cherſoneſus Taurica and Caucaſus, where it alſo appears here and there in a wild ſtate. From the northern ſide of Caucaſus it becomes more ſcarce, but on the lower parts towards the ſouth it is very common, large, and appears to be indigenous.

Formerly there were conſiderable plantations of this tree in England, particularly on the chalk hills of Surry. Mr. Evelyn inſtances thoſe of Sir Richard Stidolph near Leatherhead; Sir Robert Clayton's at Morden near Godſtone, once belonging to Sir John Evelyn; and about Carſhalton, where many thouſands of theſe trees celebrate the induſtry of the owners, and will certainly reward it with infinite improvement, beſides the ornament which they afford to thoſe pleaſant tracts, for ſome miles in circumference[5].

Little uſe having been made of the wood of late years for furniture, the old trees that have been cut down have not been always replaced with young ones, and thus the plantations of this tree have gradually diminiſhed. The wood is now principally uſed for making gun-ſtocks; and the fruit with us is only eaten ripe in deſerts, or green in pickles: ſo that the call for this tree is not equal to what it was formerly.

The Engliſh name of this tree and fruit has nothing to do with *wall*: it is *Gaul-nut*, whence we may conclude it came to us anciently from Gaul. The French call the tree *Noyer*, and the fruit *Noix*; as the Romans named it excluſively *Nux*. In German it is *Wallnuß* or *Welſche Nuß*.]

2. The leaves of the White Walnut-tree, or Hickery Nut, as it is called in North America, where it is very common in moſt of the provinces, are compoſed of two or three pairs of oblong lobes, terminated by an odd one; theſe are of a light green, and ſerrate; the lower pair of lobes are the ſmalleſt, and the upper the largeſt. The fruit is ſhaped like the common Walnut, but the ſhell is not furrowed, and is of a light colour.

[Gærtner deſcribes the outer ſhell or rind as thick, coriaceous, when ripe opening at top into four parts. The ſhell ovate-globular, four-cornered, terminated by a ſtrong, quadrangular dagger-point, marked with obſolete lines not with wrinkles; ſmooth, whitiſh, two-valved, half-four-celled: valves bony, very thick, without any viſible future on the outſide: partitions alſo bony, thick, ruſeſcent; two lateral longitudinal, and one tranſverſe at the baſe of the ſhell, but all incomplete, and forming a half-four celled cavity. Seed or kernel large, half-four-lobed; the lobes variouſly and irregularly wrinkled and tubercled.

Cateſby ſays, it is uſually a tall tree, and often grows to a large bulk, the body being from two to three feet diameter. The leaves differ from thoſe of the common Walnut, not only in being ſerrated, but in being narrower and ſharper pointed. In october, when the nuts are ripe, the outer ſhell opens and divides in quarters (as repreſented in the figure) diſcloſing the nut, the ſhell of which is thick, not eaſily broke but with the hammer. The kernel is ſweet and well taſted; the Indians draw from it a wholeſome and pleaſant oil, and ſtore up the nuts for winter proviſion. Hogs and many wild animals receive great benefit from them. The wood is coarſe-grained, yet of much uſe for many things belonging to agriculture. Of the ſaplings or young trees are made the beſt hoops for tobacco, rice, and tar barrels. For the fire no wood in the northern parts of America is in ſo much requeſt. The bark is deeply furrowed.

Cultivated in 1699 by the Dutcheſs of Beaufort[6].

β Du Roi as well as Miller gives the Juglans glabra as a diſtinct ſpecies.]

Miller ſays, it is not ſo large as the Hiccory, that the leaves are compoſed of two pairs of leaflets, beſides the odd one, narrow at their baſe, broad and rounded at their ends, ſerrate and of a light green; and that the nuts are ſmall, have a ſmooth ſhell, and are very hard and white.

[Cateſby calls it *Nux Juglans carolinenſis fructu minimo, putamine lævi*, or Pignut, and gives a figure of the fruit. He ſays, the branches ſpread more than the common Hiccory, are ſmaller, and the leaves not ſo broad; nor is the bark ſo wrinkled. The nuts are not above one-fourth part of the ſize, and both inner and outer ſhell being very thin, they are eaſily broken with the fingers. The kernels are ſweet, but being ſmall, and covered with a very bitter ſkin, they are chiefly eaten by ſquirrels and other wild animals.]

3. The Black Virginia Walnut grows to a large ſize. The leaves are compoſed of five or ſix pairs of leaflets, which end in acute points and are ſerrate; the lower pair is the leaſt, the others gradually increaſe; but the pair at top and the terminating leaflet are ſmaller: theſe leaves when bruiſed emit a ſtrong aromatic flavour, as does alſo the outer cover of the nuts, which is rough, and rounder than that of the Common Walnut. The ſhell is very hard and thick, and the kernel ſmall but very ſweet.

[Cateſby on the contrary ſays, that it is very oily and rank-taſted; when laid by however for ſome months it is eaten by indians, ſquirrels, &c. He remarks, that the leaves are much narrower, as well as ſharper-pointed than thoſe of our Walnut, and not ſo ſmooth; that the thickneſs of the inner ſhell requires a hammer to break it; and that it ſeems to have taken its name from the colour of the wood, which approaches nearer to black than any other wood that affords ſo large timber, and therefore is eſteemed for making cabinets, tables, &c.]

Mr. Miller ſays that this is the moſt valuable wood of all the ſorts of Walnut, and that ſome of the trees are beautifully veined, and will take a good poliſh; that others however have very little beauty. He adds, that this is full as hardy as our common ſort, and that there are ſome large trees of it in the Cheſſea garden, which have produced great quantities of fruit upwards of forty years[7], which have generally ripened ſo well as to grow; but the kernels being ſmall, they are of little value on that account. [It was cultivated in 1656, by Mr. John Tradeſcant, junior[8].

Jacquin gives a long deſcription of this tree and its fructification at the beginning of the ſecond volume of his miſcellanies.

Cateſby ſays, that moſt parts of North America abound with this tree, particularly Virginia and Maryland, towards the heads of the rivers, where in low rich land it grows in great plenty, and to a vaſt ſize. According to Jacquin, it abounds in Penſylvania and New Jerſey, and is common not only in Virginia and Maryland, but in Carolina, at a diſtance from the ſea, the neighbourhood of which it diſlikes. To the north of New York it becomes ſcarce, and is not found wild beyond the latitude of 41° 30'. It is cultivated however more to the northward, between New York and Albany: and it will grow, though not bear fruit in Sweden. In Penſylvania the flowers began to un-

[4] Sylva, 174, 175. [5] Ibid, 176. [6] Hort. kew. [7] He ſays this in 1759. [8] Hort. kew.

fold about the fifth or ſeventh of may, when thoſe of the Juglans regia were already paſſed. The leaves come out there about the ninth of may. The nuts ripen there and in New Jerſey at the end of ſeptember; about the middle of october they are all fallen from the trees. The leaves fall ſoon after the fruit.

The growth of this tree is remarkably quick; it ſpreads out roots horizontally to a conſiderable diſtance, and will not ſuffer any thing to grow under its ſhade. When planted in an orchard, it deſtroys all the Apple trees that are near it.

It ſeems to be hardier than our Walnut, in Penſylvania and New Jerſey, when the Peaches, Hickories and Mulberries have been much injured by froſt, the Black Walnut has ſuſtained no damage. At eight or ten years of age it begins to bear plenty of fruit, and with age increaſes in fertility. Profeſſor Jacquin obſerved trees in New Jerſey that were forty-four years old, nine fathoms in height, and three ells and a half in diameter at the diſtance of an ell from the ground. It is much planted in America near houſes for the ſhade [l].

4. Leaflets alternate, ſeſſile, oblique, acute, naked above, pubeſcent underneath, void of ſmell. Petiole and upper nerve tomentoſe. Drupe oval, tomentoſe, viſcid. Nut oblong, acuminate, the colour of the common Walnut.

It was raiſed from nuts brought from America by Kalm, and firſt bore fruit in 1774. It was ſuppoſed to be the J. nigra, but the colour and form of the fruit is different, and the leaves have no ſmell [m].]

5. This grows to a large ſize. The leaves have ſeven or eight pairs of long heart-ſhaped leaflets, broad at their baſe, where they are divided into two round ears, but terminate in acute points; they are rougher and of a deeper green than thoſe of the Black Walnut, and have nothing of the aromatic ſcent which they have. The fruit is very long; the ſhell deeply furrowed and very hard; the kernel ſmall but well-flavoured.

[In habit, trunk, and bark this is the ſame with Juglans nigra. The male aments alſo are pendulous, but they are more often in pairs than ſolitary, and without flowers at their filiform tip: in ſtructure they reſemble thoſe of J. regia, but are more oblong. The peduncles of the females are ſomewhat villoſe, round and terminating, bearing from three to five ſeſſile flowers at the extremity. Germ oblong. Stigmas purple and long. Drupe oblong-ovate, villoſe, viſcid. with very little ſmell. Nut acuminate, rough and unequal on the outſide. Kernel leſs pleaſant and more oily than our Walnut. Leaflets about ſeven on each ſide, beſides the end one, oppoſite, ſubſeſſile, villoſe when magnified, ſerrulate, ovate-oblong, acuminate, having little ſmell, the baſes nearly equal: midrib round and villoſe [n].

Jacquin ſuſpects that Linneus's ſpecific differences of this and the nigra are tranſpoſed. This and the *oblonga* of Retzius and Miller ſeem to be one ſpecies.

Native of North America. Cultivated in 1656, by Mr. John Tradeſcant, junior [o]. The order of flowering, according to Jacquin is, firſt *J. regia*, then *cinerea* and laſtly *nigra* in a few days after. The order of fruiting is different, for when the fruit of the common Walnut begins to drop on the eighth of ſeptember, the *nigra* follows at the end of the ſame month, and the *cinerea* not till after the beginning of october.]

6. This tree is of a middling ſtature. The leaves have three pairs of leaflets, of a dark green colour, ending in acute points. The fruit is oval; the ſhell white, hard and ſmooth; the kernel ſmall, but very ſweet. The young ſhoots are covered with a very ſmooth brownish bark, but the ſtems and older branches have a rough ſcaly bark, whence it has the appellation of *Shagbark* in America.

[Gærtner deſcribes the ſhell as ovate-rounded, obliquely truncate at the baſe, flatted like a lens, but four-cornered and ſhaped like a rhomb, white, ſmooth, very thick and hard. Suture linear, ſcarcely perceptible; valves boat-ſhaped, with a compreſſed, acute keel; partitions as in the alba. Kernel ſmall in proportion to the ſhell, half-four-lobed, with a ruſeſcent-yellow ſkin.

Native of North America.

Gærtner has another ſort, which he names *Juglans rubra* (Noix Pacanes de Madagaſcar); the ſhell of which is ovate-oblong, acuminate at both ends, eſpecially at top, where it is produced into a long four-cornered dagger-point; it is ſmooth, with the ſuture ſcarcely diſcernible, of a middling thickneſs, hard, and of a pale teſtaceous colour: partitions coriaceous-cruſtaceous, brittle, brown. Kernel oblong, four-lobed, like the reſt in ſtructure; with the outer cuticle entirely of a blood-red colour.

He remarks, that the firſt ſpecies only has a diſtinct ſuture to the ſhell with a ſwelling rim.

Wangenheim has two others: 1. J. ovalis, or thin-ſhelled White Walnut, with five or ſeven leaflets, the outer ones broader, the fruit (t. 23.) oval, acuminate at both ends, with a brittle ſhell. 2. J. cordiformis, the Bitter Nut, with ſeven leaflets, lanceolate, ſerrate; the fruit (t. 25.) bitter, heart-ſhaped, with a brittle ſhell.—Theſe are natives of North America.

7. Native of North America. Introduced in 1766, by Meſſrs. Kennedy and Lee [p].

Probably this may prove to be the ſame with ſome of the preceding ſpecies: perhaps n. 6.

8. Height twenty feet, as thick as the human thigh, with a comely top, and a gray bark having ſome furrows in it. Leaves terminating, always three together, three inches long, and one inch broad, thin, ſmooth, browniſh green: common petiole reddiſh, two inches long; petiolules a quarter of an inch in length. Aments axillary, two together, an inch long. The fruit hangs from the branches on peduncles an inch in length; it is yelloviſh, oval, as big as a nutmeg, having under a very thin mucilaginous pulp, a large ſhell [q], which is hard and woody. The partitions and lobes of the ſeed, as well as the parts of the flower, agree with the characters of this genus [r].

Native of Jamaica.

PROPAGATION AND CULTURE.

The common Walnut is propagated in many parts of England for the fruit, and formerly the trees were propagated for their wood, which was in very great eſteem, till the quantity of Mahogany, and other uſeful woods which have been of late years imported into England, almoſt baniſhed the uſe of Walnut.

Theſe trees are propagated by planting their nuts, which, as was before obſerved, ſeldom produce the ſame ſort of fruit as are ſown; ſo that the only way to have the deſired ſort, is to ſow the nuts of the beſt kinds; and if this is done in a nurſery, the trees ſhould be tranſplanted out when they have had three or four years growth, to the place where they are deſigned to remain; for theſe trees do not bear tranſplanting when they are of a large ſize, therefore there may be a good number of the trees planted, which need not be put at more than ſix feet apart, which will be diſtance enough for them to grow till they produce fruit; when thoſe whoſe fruit are of the deſired kind may remain, and the others cut up, to allow them room to grow, by this method a ſufficient number of the trees may be generally found among them to remain, which will thrive and flouriſh greatly when they have room; but as many people do not care to wait ſo long for the fruit, ſo the next beſt method is to make choice of ſome young trees in the nurſeries, when they have their fruit upon them; but though theſe trees will grow and bear fruit, yet they will never be ſo large or ſo long lived, as thoſe which are planted young.

All the ſorts of Walnuts which are propagated for timber, ſhould be ſown in the places where they are to remain; for the roots of theſe trees always incline downward, which being ſtopped or broken, prevent their aſpiring upward, ſo that they afterwards divaricate into branches, and become low ſpreading trees; but ſuch as are propagated for fruit are greatly mended

[l] Jacq. miſc. [m] Retzius. [n] Jacquin. [o] Hort. kew. [p] Ibid. [q] Sloan. [r] Brown. jam.

by

by tranſplanting; for hereby they are rendered more fruitful, and their fruit is generally larger and fairer; it being a common obſervation, that downright roots greatly encourage the luxuriant growth of timber in all ſorts of trees; but ſuch trees as have their roots ſpreading near the ſurface of the ground, are always the moſt fruitful and beſt flavoured.

The nuts ſhould be preſerved in their outer covers in dry ſand until february, when they ſhould be planted in lines, at the diſtance you intend them to remain; but in the rows they may be placed pretty cloſe, for fear the nuts ſhould miſcarry; and the young trees, where they are too thick, may be removed, after they have grown two or three years, leaving the remainder at the diſtance they are to ſtand.

In tranſplanting theſe trees, you ſhould obſerve never to prune either their roots or large branches, both which are very injurious to them; nor ſhould you be too buſy in lopping or pruning the branches of theſe trees when grown to a large ſize, for it often cauſes them to decay; but when there is a neceſſity for cutting any of their branches off, it ſhould be done early in ſeptember (for at that ſeaſon the trees are not ſo ſubject to bleed) that the wound may heal over before the cold increaſes; the branches ſhould always be cut off quite cloſe to the trunk, otherwiſe the ſtump which is left will decay, and rot the body of the tree.

The beſt ſeaſon for tranſplanting theſe trees is as ſoon as the leaves begin to decay, at which time if they are carefully taken up, and their branches preſerved entire, there will be little danger of their ſucceeding although they are eight or ten years old, as I have ſeveral times experienced; though, as was before obſerved, theſe trees will not grow ſo large, or continue ſo long, as thoſe which are removed young.

This tree delights in a firm, rich, loamy ſoil, or ſuch as is inclinable to chalk or marl; and will thrive very well in ſtony ground, and on chalky hills, as may be ſeen by thoſe large plantations near Leatherhead, Godſtone, and Carſhalton in Surry, where are great numbers of thoſe trees planted upon the downs, which annually produce large quantities of fruit, to the great advantage of their owners; one of which I have been told, farms the fruit of his trees, to thoſe who ſupply the markets, for 30l. per annum.

The diſtance theſe trees ſhould be placed, ought not to be leſs than forty feet, eſpecially if regard be had to their fruit, though when they are only deſigned for timber, if they ſtand much nearer, it promotes their upright growth. The black Virginia Walnut is much more inclinable to grow upright than the common ſort, and the wood being generally of a more beautiful grain, renders it preferable to that, and better worth cultivating. I have ſeen ſome of this wood which has been beautifully veined with black and white, which, when poliſhed, has appeared at a diſtance, like veined marble. This wood is greatly eſteemed by the cabinet-makers for inlaying, as alſo for bedſteads, ſtools, chairs, tables, and cabinets; and is one of the moſt durable woods for thoſe purpoſes of Engliſh growth, being leſs liable to be infected with inſects than moſt other kinds (which may proceed from its extraordinary bitterneſs;) but it is not proper for buildings of ſtrength, it being of a brittle nature, and exceeding ſubject to break very ſhort.

The general opinion is, that the beating off this fruit improves the trees, which I do not believe, ſince in the doing this, the younger branches are generally broken and deſtroyed, but as it would be exceeding troubleſome to gather it by hand, ſo in beating it off, great care ſhould be taken that it be not done with violence, for the reaſon before aſſigned. In order to preſerve the fruit, it ſhould remain upon the trees till it is thorough ripe, when it ſhould be beaten down, and laid in heaps for two or three days; after which it ſhould be ſpread abroad, when, in a little time, the huſks will eaſily part from the ſhells; then you muſt dry them well in the ſun, and lay them up in a dry place, where mice or other vermin cannot come to them, in which place they will remain good for four or five months; but there are ſome perſons who put their Walnuts into an oven gently heated, where they let them remain four or five hours to dry, and then put them up in oil jars, or any other cloſe veſſel, mixing them with dry ſand, by which method they will keep good ſix months. The putting them in the oven is to dry the germ, and prevent their ſprouting; but if the oven be too hot it will cauſe them to ſhrink.

All the other ſorts are propagated in the ſame way but as few of the ſorts produce fruit in England, their nuts muſt be procured from North America; they ſhould be gathered when fully ripe, and put up in dry ſand, to preſerve them in their paſſage to England: when they arrive here, the ſooner they are planted the greater chance there will be of their ſucceeding; when the plants come up, keep them clean from weeds; and if they ſhoot late in the autumn, and their tops are full of ſap, cover them with mats, or other light covering, to prevent the early froſts from pinching their tender ſhoots, which often cauſes them to die down a conſiderable length before the ſpring; but if they are ſcreened from theſe early froſts, the ſhoots will become firmer and better able to reſiſt the cold. Some of the ſorts being tender whilſt young, require a little care for the two firſt winters, but afterwards will be hardy enough to reſiſt the greateſt cold of this country. The black Virginia Walnut is full as hardy as the common ſort. They all require the ſame culture as the common Walnut; but grow beſt in a ſoft loamy ſoil, not too dry; and where there is a depth of ſoil for their roots to run down. The Hickery, when young, is very tough and pliable, ſticks of it therefore are much eſteemed; but the wood, when large, being very brittle is not of any great uſe. The Black Virginia Walnut is the moſt valuable.

[In ſetting the nuts, Dr. Hunter recommends drills to be made at one foot aſunder, and two inches and a half deep, into which put the nuts four inches apart. Mr. Evelyn adviſes ſome furze to be chopped among them, to preſerve them from vermin. The ſpring following the plants will come up; and in two years they will be of a proper ſize to plant out in the nurſery. They are to be planted in fields they ſhould be out of the reach of cattle, before they come out of the nurſery; but theſe ſhould be removed with great caution; the knife ſhould be very ſparingly applied to the roots; and they ſhould be planted as ſoon as poſſible after taking up, ſoon after the fall of the leaf.

In raiſing the Walnut for fruit, Mr. Boutcher recommends flat ſtones, tile-ſherds or ſlates to be buried eight inches deep, under the nuts when they are ſet: the diſtance to be ſix inches, and the depth two inches. After two ſeaſons remove them early in autumn, and plant them fourteen or ſixteen inches aſunder, on the ſame kind of bottom, or any hard rubbiſh to prevent them from ſtriking downwards, and to induce them to ſpread their roots on the ſurface. At the end of two or three years repeat this again, making the bedding at the depth of fifteen or ſixteen inches, and planting them two feet aſunder: here let them remain three or four years, when they will be fit to remove for the laſt time. The ſoil for fruit ſhould be dry and ſound, with a ſandy, gravelly or chalky bottom. The trees managed in this way, will have higher-flavoured fruit that ripens earlier, and they will bear a plentiful crop twenty years ſooner than in the uſual method. The beſt manure for them is aſhes, ſpread the beginning of winter, the land having been firſt ploughed or dug.

Since plants raiſed from the nuts of the ſame tree will bear fruit of very different quality, Mr. Boutcher adviſes the inarching one of the beſt ſorts on the common Walnut-tree; by which method the planter is both ſecure of his ſort, and he will have fruit in one-third of the time that he would obtain it from the nut. This however can be practicable only in few ſituations. The time in which I have experienced a Walnut-tree to bear from the nut is about twenty years.

If these trees be intended to form a wood, for which purpose they answer extremely well, Dr. Hunter advises to take them out of the nursery when they are three or four feet high, and to plant them three yards asunder; thinning them when their heads begin to interfere. Thus these large and branching trees will be drawn up with beautiful stems to a great height.

For raising timber, Mr. Boutcher recommends to set the nuts in february, in drills five feet asunder, eighteen inches distant in the rows, and two or three inches deep; taking up every other plant after two years. They may stand thus four or five years longer, the ground between being cropped with Turneps, Carrots, Beans, Cabbages, or other kitchen-garden plants. From time to time the least promising may be cut off below ground, when they are near touching each other, till they are left at the distance of about thirty feet.

The size to which the Walnut will attain may be judged of from what Scamozzi the architect says, as Mr. Evelyn reports; that he saw a table of Walnut tree in Lorrain, all of one piece, which was twenty-five feet in breadth, of competent length and thickness.

Leaf round, culm one-flowered, flower upright, single, naked.

DESCRIPTIONS, &c.

The Rushes have a simple grassy stem, without leaves or knots, or else knotty, with a sheathing leaf at each knot. Flowers terminating or lateral, corymbed or panicled, with the branchlets spathaceous at the base [a].

[a] Jussieu.

These plants agree with the Grasses in the glumes of their flowers, and the sheaths of their leaves, they differ in having the stems filled with pith, whereas in Grasses the stem it is well known is hollow. The Rushes form an intermediate link between the Grasses, and some of the Liliaceous plants, as Anthericum, &c. They form naturally two divisions, one without leaves, allied to Scirpus, &c., and the other with leafy stems. Some authors have made two genera of these. But all classical botanical writers, says Dr. Smith, have judiciously, preserved this very natural genus entire, notwithstanding the capsule is in some species one-celled, in others three-celled: and who can help wishing that botanists had not divided many natural genera on more trivial grounds.

Probably varieties have been exalted into species. Mons. Reynier is of opinion that Juncus effusus, inflexus, conglomeratus and filiformis are all one species; and that J. compressus, nemorosus, uliginosus, and alpinus are another [b].

1. Root perennial. Leaves round and hard. Culm round, hard and smooth, finishing in a winged feathered membrane, and bearing at top several round lateral spikes, some sessile, and others pedunculed; the stem continues above these, and ends in a hard pungent point [c]. The panicle is crowded, close, from two to three inches long. Involucre, the sheath of the outer leaf, from an inch and half to two inches in length, terminating in a stiff pungent leaf, an inch or an inch and half long: that of the inner leaf about one inch long, terminating in a sharp point about half an inch long [d].

Native of France, Italy, Carniola, Wales on the coast of Merionethshire; Inslow, Devonshire, and Braunston Burrows; Holker, Lancashire; Brancaster, Norfolk.

2. Panicle not spreading, from three to six inches long, consisting of two principal branches, one of which is from three to upwards of six inches long, the other very short, immediately dividing into lesser branches. Involucre the sheath of the outer leaf about one inch long, terminating in a very sharp-pointed pungent leaf, from three to upwards of six inches long; that of the inner about half an inch long [e].

Mr. Woodward, who is doubtful whether it be not a variety of J. inflexus, says that grows in tufts near six feet high, and that the leaves are extremely rigid and sharp. It is found on the west coast of Wales; in the salt marshes about Maldon, Essex; on the coast of Norfolk Lancashire and Scotland.]

These Sea Rushes are planted on the sea banks in Holland. The roots running deep in the sand, and matting very much, so as to hold it together. In the summer, when they are fully grown, they cut them, tie them up in bundles, dry them, and work them into baskets, &c. On the Maese, &c. they grow upwards of four feet high.

3. [Root perennial, horizontal, close, covered with ovate scales; fibres filiform, very long. Culms from one to two feet in height, upright, round, smooth: sheaths at the base striated, blunt, leafless, awned, the uppermost three times as long as the rest. Root-leaves few, very like the culms. Head of flowers roundish, solitary, seldom two together, from the fissure of the culm, bursting out below the top. Peduncles short, numerous, crowded, subdivided, with a little sheath at the base, and a lanceolate-acuminate scalelet by way of bractæ. The two calycine scales small. Stamens constantly three, never six. Seeds obconical, sharpish, white [f]: according to Withering, kidney-shaped. Native of Europe, on moist meadows and heaths.

4. Root, culms, root-leaves and peduncles as in the preceding, only larger. Culm three feet high, thicker, softer to the touch, easily broken, filled with a close pith. Panicle lateral, more or less scattered. Peduncles clustered, unequal, branched; with oblong, awned bractæ. Flowers brownish. Leaflets of the (perianth or) corolla equal. Capsule obovate, subtrigonal, very blunt, the length of the perianth. Seeds fulvous [g].

[b] Memoires, vol. 1. [c] Villars. [d] Scheuchzer.
[e] Ibid. [f] Leers. [g] Ibid.

The looſe panicle at once diſtinguiſhes this from the preceding [h]. The flowers have only three ſtamens [i].

Native of Europe, in wet meadows, marſhes, &c. They flower in july and auguſt.

Theſe are uſed ſometimes for making little baſkets. The pith of both makes wicks for watch-lights, and toys.]

Theſe with the hard ruſh grow common on moiſt, ſtrong, uncultivated lands in moſt parts of England, and conſume the herbage where they are ſuffered to remain. The beſt method of deſtroying them is, to fork them up clean by the roots in july, and after having let them lie a fortnight or three weeks, to put them in heaps, and burn them gently: the aſhes will be good manure for the land. But to prevent their growing again, and to make the paſture good, the land ſhould be drained; and then, if the roots be annually drawn up, and the ground kept duly rolled, the Ruſhes may be ſubdued.

5. Root perennial. Culms glaucous green, with the ſheaths at the baſe of a dark red cheſtnut colour, ſpear-ſhaped, but blunt at the end. Panicle bay-coloured, more upright and diffuſe than in the preceding [k]. Stamens ſix.

The hard Ruſh is common in paſtures and by road-ſides, in a moiſt ſoil; in England, Madeira, New Zealand, &c.

6. Roots tufted, ſlightly compreſſed, with a black bark, and abundance of fibres. Culms three quarters of a yard in height, with a dark-red ſhining ſheath at the baſe, and curved at top; below the curvature, for almoſt a foot in length, it puts forth on one ſide, from a cleft in the culm, many peduncles, ſuſtaining abundance of flowers [l].

Sauvages obſerves, that the top of the culm is flatted and arched over ſo as to cover the paniele.

This has been taken, by many authors, for our common Hard Ruſh.

Native of the South of Europe, in a ſtrong ſoil, ſubject to wet, but where the water is clear.

7. Root perennial, horizontal, creeping; covered with ſmooth, brown, ſtriated, imbricated ſcales: fibres filiform, but little branched, downy. Culms about a foot high, nearly erect, weak, ſtriated, ſmooth; at the baſe clothed with oblong, ſheath-like, ſtriated, brown, obtuſe ſcales, ſome of which frequently end in a little point, flowering about the middle; at the top more or leſs incurved, and ſharp-pointed. Leaves ſcarcely any, except the barren ſtems be ſo called. Panicle lateral, about the middle of the ſtem, ſomewhat corymboſe, of about five to eight flowers, of a pale whitiſh green. Sheath briſtle-ſhaped, ſcarcely longer than the panicle. Bractes two under each flower, ovate, concave, membranaceous. Peduncles moſtly ſimple, bearing one flower, rarely more, triangular, furniſhed with a few ſheath-like ſcales at their baſe. Calycine leaflets ovate-lanceolate, acute, with a membranous edge, green on the back, ſtriated, permanent, and at length becoming tawny. Stamens ſhorter than the calyx. Germ ſmall, roundiſh: ſtigmas downy, permanent. Capſule roundiſh, red-brown, poliſhed, three-valved, three-celled: the partitions oppoſite to the valves. Seeds ſmall, numerous [m].

Native of Lapland, Switzerland, Germany, Italy, Britain, on turf bogs. Dr. Smith found it on the aſcent of Mont Cenis from Italy, and on the Col de Balm, near Chamouny in Savoy. Mr. Newton, in Weſtmoreland near Ambleſide. Mr. Jackſon, at Windermoor in Cartmel, Lancaſhire. Mr. Dickſon near Derentwater in Cumberland; and on Ben Lawers in Scotland.

8. Root perennial, woody, ſtriking deep, creeping, with blackiſh fibres, putting forth cloſe tufts of ſtems and leaves. Culms a ſpan or more in length, round, ſtiffiſh, briſtle-ſhaped, upright, with lanceolate, brownish ſheaths at the baſe, accompanied by one, two or three briſtle-ſhaped leaves, involving the culm in their ſheaths. The culm is cloven at top into two ſtipular leaflets, almoſt of the ſame length, and there is a third, much ſhorter, ſtretching out laterally. At the diviſions are one or two very ſmall ſcales, villoſe within, but ſmooth without. On the middle leaflet ſit two flowers on very ſhort peduncles, and a third adheres to the cleft, embraced by the ſecond and third leaflets. The outer leaflets of the flower are larger, ſhining, of a rufous bay colour; the inner are paler and ſmaller. Stigma trifid. Capſule ſubtriquetrous, acuminate, brown [n]. Dr. Withering ſays that the flowers are from one to four: and Lightfoot, that it varies with one, two and three axillary, and almoſt ſeſſile flowers; but that the ſpecimens he found had all ſingle flowers.

Native of Lapland, Denmark, Switzerland, France, Sileſia, Scotland, on the ſummits of the Highland mountains.

9. Root perennial. Stem upright, ſtiff, from eight to eighteen inches high. Root-leaves numerous, unequal in length, the longeſt near half the length of the culm, rigid and ſpeading. Panicle ſpiked, with unequal peduncles. Glumes at the baſe of the calyx, and the edges of the leaflets white. Capſule dark red or bay-coloured, ſhining [o].

Native of moſt parts of Europe, on mooriſh heathy ground, and turf-bogs [p], flowering in june and july. It indicates a barren ſoil, and the leaves lying cloſe to the ground elude the ſtroke of the ſcythe. Horſes are ſaid to eat it [q].

10. Culm two feet high and more, round, ſmooth. Root-leaves none; but only two membranes, the rudiments of leaves. A ſingle ſtem-leaf, like the culm, but a little longer, ſtiff, mucronate, pungent. Panicle terminating, cloſely conglomerate, of a few glomes ariſing from the glume. It is allied to J. articulatus, but all the parts are ſtouter, not to mention other circumſtances. Native of the Cape of Good Hope [r].

11. This reſembles J. articulatus very much, but the flowers are more collected in heads; the heads thinner, larger, and the branches of the panicle ſimple, not ſuperdecompound: but it is chiefly diſtinguiſhed by the petals being protracted into an awl-ſhaped point. Native of North America [s].

Retzius doubts whether Plukenet's figure belongs to this ſpecies [t].

12. Root perennial, horizontal, woody, round, fibroſe. Root-leaves more than a foot in length, cylindric-compreſſed, ſmooth, fiſtular, divided internally, knotted-jointed when dry. Culm from two to three feet high, upright, round, ſmooth, leafy, with four or five joints concealed by the ſheaths. Culm-leaves bifarious, alternate, ſpreading, ſtraight, very like the root-leaves. Sheaths long, ſlightly compreſſed, ſmooth, cloathing the culm above the middle; the loweſt leafleſs, blunt, awned. Panicle terminating. Peduncles few, alternate, upright, unequal, dichotomous-branched; the lower one having an awl-ſhaped, upright, floral leaf, almoſt the length of the panicle; the reſt bracted with lanceolate-acuminate ſcales. Flowers in a ſort of head, heaped, ſmall, axillary and terminating. Calycine leaflets ovate-acuminate, membranaceous. Petals awl-ſhaped, acute, browniſh, and then turning purpliſh. Capſule three-cornered, acuminate, purpliſh, longer than the petals [u].

Native of meadows and marſhes.

13. This differs, according to Leers, from the foregoing in having the leaves cylindric, higher than the culms; the panicle more branched, and ſuperdecompound; the heads many-flowered and larger; the flowers purple and ſhining; the petals extremely acute, the three inner ones a little ſhorter than the others. Native of moiſt woods.

In Engliſh Botany it is remarked, that there ſeems to be no reaſon for making the upland variety of this plant a diſtinct ſpecies; that it is certain at leaſt, that neither the leaves being more or leſs compreſſed, nor the panicle more or leſs compound, are permanent marks of diſtinction.

The marks given in that work are the following. Root creeping, perennial. Stems from aſcending

[h] Withering. [i] Relham. [k] Withering. [l] Bauh. theat. [m] Smith ſpicil. [n] Krocker [o] Haller, Withering, Lightfoot. [p] Withering. [q] Linn. ſuppl. [r] Linn. ſpec. [s] Obſ. 1. 16. [t] Leers.

erect, ſmooth, round, a foot or more in height, with a few, alternate, ſheathing, recurved, pointed leaves, cylindrical or compreſſed, hollow, divided by numerous tranſverſe partitions, which make the dried leaves appear jointed. Panicle terminal forked, more or leſs compound, the flowers from three to five or ſix together, ſeſſile, in little heads enveloped in membranous bractes. Calyx-leaves lanceolate, pointed, longer than the ſtamens. Style very ſhort, with three long downy ſtigmas. Capſule ſharply triangular, poliſhed brown.

14. This differs from the two preceding in having either all the flowers or a few of them growing out into green and purple bundles of leaves [s].

The flowers in autumn are frequently viviparous, the germs ſhooting young leaves before the ſeeds are ripe, as in J. bulboſus.

The jointed Ruſh alſo frequently produces bunches of reddiſh leaves, inſtead of umbels of flowers, in bogs and ditches in the autumn. Theſe leaves ſeem to put on this appearance from ſome obſtruction in the growth of the plant, occaſioned by an inſect of the Coccus tribe [t].

Native of wet heaths and bogs: as Gamlingay heath, Bullington Green, Eynſham heath.

15. Root creeping. Leaves pointed, ſeldom jointed. Culms five or ſix inches high, terminating in a ſimple umbel of black ſhining flowers, with a hard lanceolate point. Capſule ſhort, and more blunt than in the preceding ſpecies [u].

Native of the Alps and the high mountains of Dauphiné.

Theſe four are probably varieties ariſing from ſituation.

16. Root perennial, horizontal, extremely fibroſe. Culm a ſpan or a foot in height, upright, ſomewhat leafy, ſmooth, compreſſed, convex on one ſide, flatter on the other, having two joints, the lower (ſometimes two) near the root, covered with ſheaths, the other below the panicle and naked. Leaves biſarious, ſmooth, ſtriated underneath, ſlightly ſheathing, ſhorter than the culm; ſheaths heaped at the baſe of the culm, compreſſed, keeled, having a very thin white membrane on each ſide, with a prominent tip. Floral leaves two, very like thoſe of the culm, upright; the lower the length of the corymb, the upper ſhorter. Panicle upright, unequal, corymbed when the fruit is ripe. Peduncles three or four, ſubdivided, the primary one always longer than the reſt: bractes lanceolate-briſtle-ſhaped. Flowers ſolitary, ſmall, coloured, terminating, moſt uſually in threes, the middle one axillary, ſeſſile. Calycine ſcales ovate, white. Petals (calycine leaflets) oblong, very blunt, almoſt upright when in blow, the three inner thinner, purpliſh. Stigmas prominent far beyond the flower. Capſule ſubglobular, almoſt oval, brown, ſhining, longer than the calyx, terminated by a ſcarcely apparent ſtyle. Seeds fulvous, pellucid [x].

With us, the bulbous Ruſh varies in height from two inches to two feet. It is ſometimes viviparous.

Native of wet meadows and heaths, and on the ſea-coaſt: flowering in auguſt.

17. Root annual, fibroſe. Culms uſually from ſeven to nine inches in height (but varying much from one to ten inches), upright, roundiſh, ſmooth. Culm-leaves few, ſomewhat ſheathing, linear, keeled. Bractes lanceolate-briſtle-ſhaped, the lower leaf-ſhaped. Flowers ſolitary, ſeſſile; a ſingle one always axillary in each diviſion of the culm; the reſt towards the ends of the branches, on one ſide and remote. Calycine ſcales ovate-acuminate, white. Petals (calyx-leaves) lanceolate-awl-ſhaped, very ſharp, the three inner ones ſhorter. Capſule oblong, ſubtrigonal, very blunt, brown, ſhining, ſhorter than the calyx, three-valved. Receptacle awl-ſhaped, tripartile, numerous brown ſeeds affixed on both ſides to each diviſion.

In the ſmaller plants the leaves are very ſlender, not angular, but folded together. Flowers moſtly in pairs, and only one ſeſſile, but in all, the ripe capſules are brown, ſhining and ſhorter than the calyx [y]. This is likewiſe found ſometimes viviparous [z].

[s] Leers. [t] Lightfoot. [u] Villars. [x] Leers.
[y] Ibid. [z] Withering. [a] Lightfoot.

Native of wet gravelly or ſandy paſtures, eſpecially where water ſtagnates in winter. It flowers from may to auguſt.

18. Root perennial, ſimple, jointed, with ſolitary radicles, covered with the remains of the leaves of the preceding year. Culm a ſpan high, upright, round, ſmooth, leafy. Stem-leaves two; the lower of the ſame length with the culm, awl-ſhaped, roundiſh, compreſſed a little, ſcarce apparently ſtriated, brown at the tip, channelled at the baſe, with membranaceous, embracing margins; the upper ſhorter, and not attaining the ſame height with the preceding. Spathe, or third terminating leaf awl-ſhaped, channelled, purpliſh with a brown tip, an inch long. From this proceed two ſtiff peduncles; the outer very ſhort; the inner the length of the ſpathe, and ſtraight; each terminated by a two-flowered, two-valved glume; valves ſmall, membranaceous, white, concave, ſharpiſh, equitant at the baſe, one third of the length of the flowers. The three outer ſegments of the calyx lanceolate, narrower, ſtiffer, ſtriated on the back, purple; the inner broader, thinner, flatter, white ſcarcely tinged with purple; all ſharp, permanent, attenuated and withering as the fruit ripens. Filaments ſcarcely the length of the calyx. Germ almoſt the length of the calyx, ovate, three-ſided. Capſule longer than the calyx, ſhining, brown, rufous at the tip, half-three-celled, many-ſeeded: valves ovate, bluntiſh, a little recurved at the tip; partitions from the centre to the baſe, gradually vaniſhing towards the middle. Seeds three-ſided, acuminate at both ends, ſhining, whitiſh. Linneus at firſt confounded this with J. buſonius, from which it is very diſtinct. It is a native of Sweden in deep wood bogs. Linneus had it from Lapland and Upland. Probably it has not been diſtinguiſhed from J. buſonius, and may perhaps be a native of Britain [a].

19. Root perennial, brown, horizontal, knobbed, ſending forth very long fibres perpendicularly. Culms ſeveral, quite ſimple round, upright, from three to ſix inches high, with a few ſheaths at the baſe. On each culm a ſingle leaf, awl-ſhaped, round, ſlightly grooved, acuminate and mortified at the end, almoſt upright, ſheathing at the baſe, varying in ſituation, but never at the bottom of the culm. Root-leaves ſome, of the ſame ſtructure. A two-leaved or one-leafed glume, lanceolate-awned, thin, membranaceous, pale-brown, terminates the culm. A ſhort, branched peduncle collects from three to ſeven flowers (or ten, according to Haller), on very ſhort pedicles, and large in proportion to the plant; cloſed, acuminate, triangular. Calycine glumes roundiſh, concave, blunt, ſmall, purpliſh brown. Leaflets of the perianth lanceolate, concave, mucronate, rigid, very dark bay, ſhining. Filaments very ſhort; anthers linear, long, yellow, almoſt equalling the flower. Stigmas writhed ſpirally, red, villoſe, and double the length of the flower. Capſule blunt, grooved. Seeds few, ovate, acuminate. The whole plant is ſmooth.

Native of the Alps, flowering in june [a]. See J. caſtaneus, *Smith brit.* 383.

20. Root perennial, fibroſe, ſimple, perpendicular. Culm ſeldom an inch in height, round, marked with a ſingle ſtreak, covered at bottom with the remains of withered leaves, at top with the ſheath of the ſingle leaf, which is the length of the ſcape, ſhining, twice as thick as the culm, tubular, mortified at the end, channelled below, ſheathing the culm up to the middle. Leaves four or five ſurrounding the lower part of the culm, and changing into ſcales. Glume terminating; outer valve large, ovate, acuminate, very dark purple, green on the back, keeled; lower only half the ſize, acute, all dark-purple. Leaflets of the perianth of the ſame colour with the glume, but the three outer marked with a greeniſh line along the middle of the inner ſide, lanceolate, narrower at bottom. Three of the filaments oppoſite to the inner leaflets of the perianth near the baſe, the three others fixed at the bale of the germ, all, however, finiſhing at the ſame height. Germ blunt, ſomewhat ciliate at the corners. Stigmas purpliſh, pubeſcent, the length of the ſtyle.

[a] Smith. [a] Jacqu. auſtr.

This

This Rush has the appearance of Schoenus ferrugineus, and is a native of the Lapland alps, where it was found by Montin[f]. Also of the Highland of Scotland.

21. Culms in tufts, three inches high or more, soft, covered at the base with brown sheaths. Culm leaves two, round, fistular, half the length of the culm, from broad sheaths. Head of unequal height, with the three flowers pedunculed. The two first glumes large, keeled, ovate-lanceolate, bay with a mixture of red, white at top: the third glume within the others, and not two at the base. Outer leaves of the flower larger, of a bay rufous colour; the inner paler. Capsule large, ovate and three-sided. Seeds acuminate[g].

Root-leaves sheathing the culm, flat, like those of Grass. Culm without branches or leaves, terminated by a glume, within which are three sessile flowers[h].

Native of the Lapland alps, Denmark, Switzerland, Austria, Italy, Siberia, Scotland and Wales; and near Keswick in Cumberland.

22. Root perennial, with numerous brown fibres, and short pointed shoots, so that it is somewhat creeping. Culms many, about a span or more in length, nearly upright, leafy, naked above, simple, smooth, striated, round, furnished with three or four joints, which are not protuberant. Root-leaves numerous, three or four inches long, three lines, or three lines and a half broad, somewhat narrower at the base, a little concave, dull green on the upper surface, smooth and rather glossy, beneath paler green and slightly glossy, at the edges especially, covered with a few long hairs, which are most numerous towards the base of the leaf, often of a reddish colour, a little blunt, and as it were cut off at the point. Flowers forming a spreading panicle. Flower-stalks of unequal lengths, a few simple, most of them proliferous, dichotomous or trichotomous, finally stretching out backwards, all supporting a single flower, the intermediate ones sessile. Perianth-leaves oblong, pointed, keeled, concave, purplish-brown and permanent. Germ pointed.

This and the following species are distinguished by their grass-like hairy leaves. J. pilosus differs from campestris, not only in its place of growth, but in having its flowers stand singly, and not in clusters. Whilst the campestris delights in exposed places, the pilosus is found only in woods and shady situations. From this circumstance we may perhaps account for its flowering earlier than any of the others: for if the season be not very unfavourable, it will begin to flower in february, and is usually out of bloom the beginning of may[i].

23. Culm a foot in height at most. Root-leaves scarcely two lines in breadth, subhirsute, but with the sheath smooth, springing from a little tuft of brown, membranous scales. Culm-leaves four or five, narrowing insensibly, springing from a sheath as long as themselves, and producing a pencil of long silky hairs at its separation from the stem. Flowers very numerous, in a false umbel, on peduncles that are filiform, and diminish in length as they are higher on the stem, insomuch that the lower ones stand higher at top than the upper ones. They have at their base lanceolate, villose, russet-coloured bractes. Flowers rude, small, solitary. Calyx-leaves two-thirds only of a line in length, and less than half a line in breadth, blunt, ending in a point or short awn; they vary in colour, being whitish, russet, pale yellow or brown, but they are constant in figure and size[k]. Native of the Alps.

24. The leaves of this are not only much broader and more concave, but more sharply pointed than those of the *pilosus*; it flowers three weeks or a month later; and when the flowering is over, the peduncles of the *pilosus* are more reflexed or pendulous than those of the *sylvaticus*. It flowers in may, or earlier, if the season be mild. In some situations this species is very large and tall, but it more usually occurs with a stalk little more than a foot high. If the height of *campestris* be nine inches, that of *pilosus* is eleven, and of *sylvaticus* fifteen. It is not uncommon in woods[l].

25. Height three feet. Leaves scarcely a line in breadth. Panicle of the umbel convex. Two long narrow leaves rise above it, near one another, at the base of the umbel, and a little higher. Stipules under the branches long, stiff, jagged: bractes short, ovate-lanceolate, snow-white, shining. Flowers the handsomest of any in this genus. Calyx-leaves white, smooth; the inner three lines long; the outer only half that length; all lanceolate[m].

Native of the Alps of Switzerland, &c.

26. Root perennial, somewhat woody, with numerous blackish fibres, creeping. Culm simple, from three to nine inches high, upright, leafy, somewhat enlarged at bottom, round, smooth, without joints. Leaves pointed, the tips often mortified, of a reddish brown colour, without any membrane. Two small, upright, unequal leaves, placed under the spikelets, terminate the stalk. Spikelets generally three, subovate, upright when the plant is in flower, on unequal pedicels, the lowest spikelet nearly sessile. Peduncles filiform, proceeding from a small sheath edged with hairs. Flowers ten or twelve in each spikelet, sessile. Four small scales, ovate-acute, membranous, unequal, much shorter than the calycine leaflets, surround the base of each floret. Calycine leaflets lanceolate-acuminate, spreading, permanent, shining, keeled, brownish-purple. Anthers oblong, the length of the calyx, four-grooved, two-cusped, when the pollen is shed becoming twisted. Seeds usually three, roundish, olive-coloured. Thus the Field-Rush appears in its most usual state in dry pastures: in such situations it has seldom more than three or four spikelets: in moister richer soils, particularly in boggy ground, it often has a much greater number. But although it may vary in size and number of parts, it still continues very distinct from the *pilosus*. It flowers in april and may, and ripens its seeds in june. It indicates a dry, and consequently not luxuriant pasturage. The hairs proceed from the edges of the leaves, and appear as if some animal had left its hairs on them by rubbing[n].

27. Linneus, in his *Flora Suecica*, considers this as so nearly allied to the preceding, as to be perhaps only a variety. In his *Flora Lapponica*, however, he has figured and described it thus. Root-leaves ten or twelve, upright, acuminate. Culm very slender, with three small leaves, one at the base, a second in the middle, and a third at the top. Spike single, loose, ovate-oblong, composed of many flowers.

Dr. J. E. Smith affirms that this and *campestris* are perfectly distinct. It is five or six inches high, with a terminating spike, pointing almost horizontally, about half an inch long[o].

Native of Lapland, Denmark, Scotland.

28. Culms leafy, round, as thick as the little finger, from four to six feet high. Leaves alternate, grassy, hard, even, somewhat nerved, scarcely the length of the culm. Panicle conglomerate, not very spreading; flowers scatteringly conglomerate. It is allied to *J. pilosus*, but is much larger even than *J. acutus*.—Native of the Cape of Good Hope.

29. Scarcely a foot high, very smooth. Culm round, covered with sheaths at the base. Leaf single, round, awl-shaped, straight, longer than the culm. One large, upright flower terminates the culm. Calycine valves upright, acute, alternately shorter. Stamens and pistils shorter than the calycine valves[p].

GENERIC CHARACTER.

* *Male flowers* ſeſſile, cluſtered, on the leaves, ſtem, frond.

CAL. ſcarce any.

COR. none.

STAM. *Filaments* hardly any. *Anthers* ovate, one-celled, gaping at the tip.

* *Female flowers* on the ſame, or on a ſeparate individual.

CAL. *Perianth* upright, tubular; truncated, crenated, or laciniated.

COR. *Calyptra* ſeſſile, ſmaller than the perianth, ſubgloboſe, cloſed on every ſide, membranaceous, tender, crowned by the ſtyle, at length burſting at the tip.

PIST. *Germ* oblong, involved by the calyptra, ſeſſile; *ſtyle* ſtraight, ſhort, paſſing through the top of the calyptra; *ſtigma* ſimple.

PER. *Capſule* ſeated on a long and very tender briſtle, globoſe, one-celled, at length gaping longitudinally into four *valves*, which are equal, ſpreading, permanent.

SEEDS many, globoſe, adhering by twiſted elaſtic *threads* fixed to the bottom, tip, diſk, or margin of the valves.

OBS. *Several germs are often found in one perianth, of which, however, only one grows to maturity.*

The Stemleſs Jungermanniæ *have their anthers within the ſubſtance of the fronds, and want the perianth of the female flowers: Qu. Whether they do not conſtitute a diſtinct genus?*

Thirty ſpecies of theſe Moſſes are arranged in five ſubdiviſions, in the fourteenth edition of Syſtema Vegetabilium. Mr. Huſſon has thirty ſpecies in the ſecond edition of his Flora Anglica. Dr. Withering has forty-eight ſpecies in the third edition of his Arrangement of Britiſh Plants. He diſtributes them into four ſubdiviſions:

A. Plant unbranched, and without a midrib.

B. 1. Leaves winged: fruit-ſtalks terminating.
2. Leaves winged: fruit-ſtalks lateral, or at the baſe.

C. 1. Leaves winged: leaflets with appendages: fruit-ſtalks terminating.
2. Leaves winged: leaflets with appendages: fruit-ſtalks lateral, or at the baſe.

D. Shoots tiled or imbricate.

Figures of theſe Moſſes will be found in Dillenius, Micheli, Vaillant, Hedwig, Dickſon, Schmidel, Flora Danica, Engliſh Botany, Moriſon, Withering, &c.

Many of the ſpecies are beautiful microſcopic objects, according to the remark of Dr. Withering.

JUNGERMANNIA. See *Mnium*.

JUNIBANSIA. See *Curtiſia*.

JUNGIA. (*So named from Joachim Jungius, M. D. Profeſſor at Hamburgh: author of* Doxoſcopia, 1662, *and* Phytoſcopia, 1678.)

Lin. gen. Schreb. n. 1348. *ſuppl.* 58. *Juſſ.* 175.

Claſſ. 19. 5. Syngeneſia Polygamia Segregata.

Nat. order of *Compoſitæ Oppoſitifoliæ*. *Cinarocephalæ*. Juſſ.

GENERIC CHARACTER.

CAL. *Common* many-leaved: *leaflets* ſomewhat ſpreading, linear, obtuſe, channelled, ſhorter than the partial perianth, involving three or four flowers.

Perianth partial, many-leaved, almoſt equal, many-flowered: *leaflets* oblong, channelled, obtuſe, upright.

COR. *Compound* uniform; *corollets* hermaphrodite, equal; *proper* one-petalled, funnel-ſhaped; *tube* gradually widened: *border* two-lipped: the *exterior diviſion* rolled back, longer, linear, toothed at the tip: the *interior* two-parted; the *two ſegments* upright, ſharp.

STAM. *Filaments* five, very ſhort, inſerted into the tube. *Anthers* connate.

PIST. *Germ* inferior, linear, cornered. *Style* filiform. *Stigmas* two, revolute, obtuſe.

PER. none. Calyx unchanged.

SEED ſolitary, cornered. *Down* long, ſeſſile, feathered.

REC. chaffy. *Chaffs* reſembling the calycine leaflets.

ESSENTIAL CHARACTER.

Cal. common three-flowered. *Recept.* chaffy. *Flowers* tubular, two-lipped; outer lip ligulate, inner two-parted.

SPECIES.

1. Jungia ferruginea.
Lin. ſyſt. 797. *ſuppl.* 390.

DESCRIPTION, *&c.*

Stems woody, covered with a ferruginous down. Leaves alternate, petioled, remote, flat, rounded, five-lobed, cordate at the baſe: lobes rounded, blunt; they are hirſute, and underneath hoary. Panicle terminating, large, decompounded. Heads of flowers ſmall, heaped. Native of South America.]

JUNIPERUS (*of Pliny, &c.*)

Lin. gen. n. 1134. *Reich.* 1240. *Schreb.* 1552. *Gærtn. t.* 91. *Tournef. t.* 361. *Juſſ.* 413. *Tournef.* 361.

Sabina. *Boerh.* 2. 207. Cedrus. *Tournef.* 361.

Claſſ. 22. 13. Dioecia Monadelphia.

Nat. order of *Coniferæ*.

GENERIC CHARACTER.

* *Male.*

CAL. *Ament* conical, conſiſting of a common ſhaft on which are diſpoſed three oppoſite flowers in triple oppoſition; a tenth terminating the ament: each flower has for its baſe a broad, ſhort, incumbent *ſcale* affixed to the column of the receptacle.

COR. none.

STAM. *Filaments* (*in the terminal floſcule*) three (four to eight) awl-ſhaped, united below into one body: (*in the lateral flowers* ſcarce manifeſt;) *Anthers* three, diſtinct in the *terminal flower*, but faſtened to the calycine ſcale, in the *lateral* ones.

* *Female.*

CAL. *Perianth* three-parted, very ſmall, growing to the germ, permanent.

COR. *Petals* three, permanent, rigid, acute.

PIST. *Germ* inferior. *Styles* three, ſimple. *Stigmas* ſimple.

PER. *Berry* fleſhy, roundiſh, marked on the lower part with three oppoſite obſcure tubercles, (from the calyx having grown there) and at the tip by three teeth (which before were the petals), umbilicated.

SEED three *oſſicles*, convex on one ſide, cornered on the other, oblong.

ESSENTIAL CHARACTER.

MALE. Calyx of the ament a ſcale. *Cor.* none. *Stam.* three.

FEM. *Cal.* three-parted. *Pet.* three. *Styles* three. *Berry* three-ſeeded, irregular with the three tubercles of the calyx.

DESCRIPTIONS, *&c.*

1. Spaniſh Juniper grows to the height of twenty-five or thirty feet, and ſends out many branches, which form a ſort of pyramid. Leaves acute, lying over each other in four rows, ſo as to make the branches four-cornered. Berries very large, black when ripe. Native of Spain and Portugal. Cultivated in 1759 by Mr. Miller.

2. Barbadoes Juniper or Cedar, or Jamaica berry-bearing Cedar has been confounded with the Bermudas Cedar; but the branches of this ſpread very wide, the leaves are extremely ſmall, and are every where imbricate; the bark is rugged, ſplits off in ſtrings, and is of a very dark colour. The berries are ſmaller than thoſe of the Bermudas Cedar, and are of a light brown colour when ripe.

It is a native of the Weſt Indies, where it riſes to be one of the largeſt timber trees: the wood is frequently fetched from thence by the inhabitants of North America, for building ſhips. [It is alſo an inhabitant of China and Japan.] Cultivated in 1759, by Mr. Miller.

3. Bermudas Juniper, commonly called Bermudas Cedar, whilſt young, has acute-pointed leaves, which ſpread open, and are placed by threes round the branches; but as the trees advance their leaves alter, and the branches become four-cornered; the leaves are very ſhort, and lie over each other by fours round the branches. The berries are produced towards the ends of the branches, and are of a dark red colour, inclining to purple. The wood has a very ſtrong odour, and was formerly in great eſteem for wainſcotting rooms, and alſo for furniture.

[Native of America. Dr. Patrick Browne ſays, that it grows very plentifully in moſt of the Blue Mountains of Jamaica, where it is frequently cut down for planks, &c.; that it is a good timber-wood, admired for its ſmell, lightneſs, and cloſe even grain; very fit for wainſcotting, and all the inward parts of cabinet-work.—Cultivated in 1700 by the Earl of Clarendon[a].

4 Loureiro deſcribes the Chineſe Juniper as a ſhrub of three feet in height, with twiſted and very ſpreading branches. Leaves awl-ſhaped, hardiſh, dark green—according to Linneus ſpreading, green on both ſides, more cluſtered than in the other ſorts, faſtened at the baſe, ſcarcely pungent, extremely diſtinct by the denſity of the leaves[b]. Native of China.

5. Mr. Miller makes two ſpecies of the Common or Cypreſs-leaved, and Tamariſk-leaved or Berry-bearing Savin, as he calls it.] The former, he ſays, has by many been ſuppoſed to be only an accidental variety; but the branches grow more erect, the leaves are ſhorter, and end in acute points which ſpread outwards. It riſes to the height of ſeven or eight feet, and produces great quantities of berries: whereas the Tamariſk-leaved Savin very rarely produces either flower or ſeed in our gardens. β. This ſends out its branches horizontally, and ſeldom riſes more than three or four feet high, but ſpreads to a conſiderable diſtance every way. Leaves very ſhort, acute-pointed, running over each other along the branches, with the ends pointing upwards. The berries are ſmaller than thoſe of Common Juniper, but of the ſame colour, and a little compreſſed. The whole plant has a very rank odour when handled. [There is a variety with variegated leaves. Savin is a native of the South of Europe and the Levant. It was cultivated here in 1562, as we learn from Turner[c]: but probably it is a much older plant in our gardens.

Profeſſor Pallas ſays, that in the Cherſoneſus taurica, where it is very common, the Savin is often found with a trunk a foot in diameter; that it grows upright there like a Cypreſs, whereas by the Tanais it is procumbent, the branches extending on the ſand ſeveral fa-

[a] Hort. kew. [b] Mant. [c] Hort. kew.

thoms; that the wood very much resembles that of J. lycia, but has a more cadaverous smell, and the leaves are more fetid.

6. Leaves mutually opposite by threes, fastened at he base by their inner side, in the new shoots imbricate in four rows, giving them the appearance of being quadrangular; the year following these spread from the branch at an acute angle, and appear to be disposed in six rows or longitudinal phalanxes [a]. Berry dark blue, covered with a whitish resinous meal [b].

Native of North America, the West India islands and Japan.

It grows to be one of the largest and highest timber trees in Jamaica, affording very large boards of a reddish brown colour, close and firm contexture, shining, very odoriferous, extremely like Bermudas Cedar, being towards its outsides of a paler colour and looser contexture. The bark is thin, and ready to drop off in great pieces, appearing somewhat contorted, of a reddish brown colour. This tree is much used for wainscotting rooms, making escritoirs, cabinets, &c. Cockroches and other insects disliking the smell of it [c].

I should suspect Sloane's tree to be the Bermudas Cedar.

Mr. Miller has two species. (n. 3, 4.)] The first he names J. virginiana, which he says grows naturally in most parts of North America, where it is called Red Cedar, to distinguish it from a sort of Cypress, which is called White Cedar there. Of this there are two or three varieties; one of which has leaves in every part, like those of the Savin, and upon being rubbed, emit a very strong ungrateful odour: this is commonly distinguished in America by the name of Savin-tree. There is another with leaves very like those of Cypress; but as these generally arise from the same seeds, they may be supposed to be only seminal varieties.

The second he names J. caroliniana. The leaves of this are like those of the Swedish Juniper, but the upper leaves are like those of the Cypress; and this difference is constant, if the seeds are carefully gathered from the same tree; but it often happens that persons who gather the seeds in America mix two or three sorts together. In the Virginia Cedar all the leaves are like those of Juniper. The Carolina Cedar, as the gardeners call it, is also a native of Virginia.

Cultivated here in 1664, according to Evelyn.

7. Juniper is a low shrub, seldom rising more than three feet high, sending out many spreading tough branches, which incline on every side, covered with a smooth, brown or reddish bark, with a tinge of purple. Leaves narrow awl-shaped, ending in acute points, placed by threes round the branches, pointing outwards, bright green on one side, and gray on the other, continuing through the year. The male flowers are sometimes on the same plant with the females, but at a distance from them; but they are commonly on distinct plants. The female flowers are succeeded by roundish berries, which are first green, but when ripe of a dark purple colour. [They continue on the bush two years, and are sessile in the axil of the leaves. Gærtner calls the fruit *galbulus*; and describes it as spherical, berried, blackish-blue, covered with a bloom, marked at top with three raised dots, and a three-forked groove, received at bottom in a very small starred involucre: it is juiceless, spongy-fleshy, and contains three stones. These are bony, one-celled, valveless, gibbose, on one side from a broad and convex back narrowed towards the base and keeled, on the other very bluntly angular, or marked with a longitudinal ridge, and at the base on the outside with four oblong little excavations, into each of which a balsamiferous gland is inserted. Seed single, ovate-acuminate, dun-coloured with a brown mark at the base. Geoffroy first remarked these glands in 1721; but he reckoned only eight, whereas there are twelve, namely four to each seed.

Juniper is common in all the northern parts of Europe, in fertile or barren soils, on hills or in valleys, in open sandy plains or in moist and close woods. On the sides of hills its trunk grows long, but on the tops of rocky mountains and on bogs it is little better than a shrub [e]. In England it is found chiefly on open downs, in a chalky or sandy soil. In the Southern countries of Europe it is less common, except in more elevated situations.

When planted in a good soil it will grow fifteen or sixteen feet high, and form a well-looking bushy shrub. Mr. Evelyn mentions a slender bush of two feet in height, brought from a common, which in ten years measured seven feet square and eleven feet high, and would have been of a much greater altitude and farther spreading, had it not continually been kept shorn. —It is easily transplanted, and bears cropping. Grass will not grow beneath it, but the *Avena pratensis* destroys it. The wood is hard and durable. The bark may be made into ropes. Spirit impregnated with the essential oil of these berries is every where known by the name of Juniper water or Gin. The berries sometimes appear in an uncommon form: the leaves of the calyx grow double the usual size, approaching, but not closing, and the three petals sit exactly close, so as to keep the air from the *Tipulæ Juniperi*, which inhabit them. Other insects feed on this shrub, as *Cimex juniperinus*, *Thrips juniperina*, and *Coccinella novempunctata*. Horses, sheep and goats eat it. Gum Sandarach, known under the name of *Pounce* in its powdered form, is the produce of this shrub [f].]

β. Swedish or Tree Juniper rises to the height of ten or twelve (even sixteen or eighteen) feet; the branches grow more erect than those of the common Juniper; the leaves are narrower, end in more acute points, and are placed farther asunder on the branches; the berries also are longer. It is a native of Sweden, Denmark and Norway. Mr. Miller insists on this being a distinct species, because having raised both from seed for many years, he never found them alter. [Plants raised from seeds have a tendency to grow higher than those which are cropped by cattle; and this misled Mr. Miller, for these are certainly no more than varieties.

γ. Nor is the Alpine or Mountain Juniper at all different from the Common, though the leaves be broader and thicker; the berries rather oval than spherical.

8. Branchlets three-sided. Leaves sessile (by no means adnate), altogether as in J. communis, but larger in all the parts. Berries ruiescent, the size of a hazel-nut [g].]

Height ten or twelve feet, branched the whole length. Branches small and taper, having no angles, as most of the other Junipers have. Leaves small, obtuse, imbricate. Male flowers at the ends of the branches in conical scaly aments: the berries below from the side of the same branch.

[This shrub will be feathered from top to bottom, if left untouched from the first planting, or if not crowded with other trees. Leaves awl-shaped, and finely spread open: they are very short, sharp-pointed, and give the shrub a fine look. The large brownish red berries make a handsome appearance when they are ripe [h].

Native of Spain, Portugal, and the South of France, —Cultivated in 1739, by Mr. Miller [i].]

9. Phenician Cedar or Juniper grows with its branches in a pyramid; the lower ones have short, acute-pointed, grayish leaves, pointing outwards; but those on the upper branches are dark-green and imbricate, ending, however, in acute points. The male flowers are produced at the extremity of the branches, in a loose scaly conical ament, standing erect on a short peduncle: the fruit is sometimes upon the same tree, at a distance from the male flowers, but more generally on separate trees. Berries pale yellow when ripe, about the size of those of common Juniper.

[Leaves ovate, convex, blunt, very minute [k]. Branches, branchlets and fronds thick, dichotomous, and even woody, with the remains of scales; the older branches having a dusky testaceous bark. Fronds imbricate, with decurrent leaflets in threes, with very long sharp points [l].

[a] Linn. [b] Withering. [c] Linn. mant.
[d] Hunter in Evel. [e] Hort. kew. [f] Linn. [g] Pallas.

Ray regards this as scarcely different from the next species *.

Native of the South of Europe and the Levant. Cultivated in 1683, by M. James Sutherland †.] Mr. Miller says, he has frequently received the berries from Portugal.

10. Lycian Cedar has the branches growing erect, and covered with a reddish-brown bark. Leaves small, obtuse. Male flowers at the ends of the branches in a conical ament; and the fruit single from the axils below them on the same branch. Berries large, oval, and when ripe brown.

[According to Pallas, it is entirely prostrate, with the trunk branching from the very bottom, often thicker than the human arm. This and the branches are often compressed or variously deformed, with scarcely any outer bark. Wood smelling very strong like the American Cedar. Branches and extreme branchlets wand-like, straight, thickish, covered with a testaceous bark. Shoots dark-green, dichotomous, imbricate, with leaflets decussately opposite, scale-form, sharp. Berries terminating, globular, middle-sized, black when ripe, with a glaucous bloom; containing three or four stones. Seeds ovate-oblong, convex on the outside, angular-three-sided within.

Pallas remarks, that it is with difficulty distinguished from Savin; that the bruised leaves have the same smell; and that it differs from it principally in the greater thickness of the shoots, and in the leaflets being acute and less clustered. He says that the leaves are never in threes with them.

Native of the South of France, the Levant and Siberia.] Mr. Miller says that he received it both from Spain and Italy. He cultivated it in 1759.

11. Stem frutescent, erect, branched, branches spreading, branchlets three-sided. Leaves sessile, lanceolate, somewhat glaucous, with a double line above. Drupe testaceous, with a glaucous bloom, often three times as long as the leaves, large, roundish, angular, and marked with six or nine retuse tubercles. Nut subovate, large, with three small cells, very hard, hollowed above with three lines; kernel solitary, ovate-oblong, fixed by a pellicle to the bottom of the cells.

Native of mount Cassius: and probably the same with the great Junipers observed by Belon on mount Taurus, and which he describes as rising to the height of a Cypress, and bearing a sweet fruit, the size and shape of an olive ‡.

12. This usually shrubby, with the stems lying prostrate on the rocks, the principal ones often the thickness of the human arm. Branches thickish, testaceous, the younger ones imbricate, with the remains of leaves changed into acuminate scales, which at length are cloven, and fall. Shoots green, dichotomous, imbricate with leaves that are decussately opposite, in pairs, glaucous-green, less crowded.

Respecting the leaves, there are two varieties of this Juniper. In one, the leaves are mostly scale-form, decurrent, with a short awl-shaped point, and closely imbricate, with here and there a longer needle-shaped leaf on the branchlets. This is commonly male, or with female flowers only at the incurved three-leaved tips of the branchlets. The other is commonly berry-bearing all over, except the outer younger shoots; and the leaves, like those of J. Oxycedrus, are acicular or needle, shaped, spreading from the base, almost as long as the berries, keel-grooved, compressed. Berries globular, more bitter than the Common Juniper, blackish when ripe, but appearing blue from the white meal that covers them, peduncled as it were by standing on a leaflet's thickened branchlet, containing one or two stones; kernels ovate globular, large, margined with a blunt rib, or four-grooved, yellowish.

Native of Siberia, and totally different from J. lycia ‖.

The virtues of some species of this genus are very considerable. The *Common Juniper* is celebrated for its diuretic powers: the berries are principally used, and from them a spirit is prepared and kept in the shops, and used plentifully in hydropic cases, and in diuretic draughts; boiled in water these berries give a sweet decoction, tasting very strongly of the Juniper, and from the decoction may be obtained a quantity of sugar: the berries are also considered as stomachic, carminative, and diaphoretic. Of their efficacy in many hydropical affections we have various relations from physicians of high authority; as Du Verney, Boerhaave, Hoffman, Van Swieten, &c. Authors, however, do not seem perfectly agreed which preparation of the Juniper is most efficacious; some preferring the rob or inspissated decoction, while on the contrary Dr. Cullen disapproves of this, as having unavoidably lost a good part of its essential oil, (in which he supposes a great part of the efficacy of the Juniper to consist); in the boiling. Hoffman, however, strongly recommends the rob, and declares it to be of great utility in weakness of the stomach and intestines; and particularly serviceable when such cases occur in old people: but as the modern practice generally depends on more powerful, or stronger medicines, (the Juniper being considered in a secondary view), it may perhaps be allowed that as good a form as any for its use is that of a simple decoction; and this, either by itself, or with the assistance of a small quantity of gin, may be a useful drink for hydropic patients. Medical writers have also commended it in scorbutic cases, and in some cutaneous diseases; but in these cases a decoction prepared from the wood and the tops of the plant is thought preferable to that from the berries. We are told by Linneus that the Swedes prepare a beer from the berries, which they consider as very efficacious in scorbutic cases; and that the Laplanders drink infusions of Juniper-berries as we do tea and coffee, for the same purpose. Juniper wine is sometimes made, and is said to be a very wholesome one. Gum Sandarach, used for pounce, &c. is the gum or resin of old Junipers. *Juniperus Sabina, or Savine*, is more powerful in its operations than the former, and has been much famed as an emmenagogue: it heats and stimulates the whole system very considerably, and is said to promote the fluid secretions: the leaves and tops of Savine have a moderately strong, disagreeable smell, and a hot, bitterish taste: they give out their active matter to watery liquors, and still more completely to rectified spirit; distilled with water they yield a large quantity of essential oil. Decoctions of the leaves, inspissated to the form of an extract, retain a considerable share of their pungency and warmth, together with their bitterness, and have some degree of smell, but not resembling that of the plant itself. On inspissating the spirituous tincture, there remains an extract consisting of two distinct substances; of which one is yellow, oily, bitterish, and very pungent; the other black, tenacious, less pungent, and very astringent. Savine, when used for the purpose of an emmenagogue, has been sometimes found to be too powerful; and it has even been supposed to possess the power of causing abortion: but this seems to be extremely doubtful, and it sometimes fails as an emmenagogue; and its heating qualities are such as to require caution in its administration. In the Edinburgh Infirmary it appears to have been used with great success by Dr. Home, in cases of amenorrhoea, given in powder, from a scruple to a dram, twice a day. Upon the whole, Savine may be considered as a warm stimulant and aperient, and particularly serviceable in uterine obstructions proceeding from a laxity or weakness of the vessels, or a cold, sluggish indisposition of the juices. The distilled oil, exclusive of the powers just mentioned, is also a strong diuretic, and impregnates the urine with its smell. The dose is two or three drops, or more.

Juniperus Lycia.—This is the species from which is taken the gum-resin called Olibanum, which has a strong smell, and a bitterish somewhat pungent taste. When burnt it diffuses a fragrant smell, and is supposed to have been the incense used by the ancients in their religious ceremonies, (though not the same with the substance known by that name in the shops). It is much employed by the Roman Catholics in their churches for similar uses. As a medicine it has chiefly been used in disorders of the head and breast, and in haemoptoes, and alvine and uterine fluxes: the dose from a scruple to a dram or more. It has also been used

uſed in plaſters, &c. and as an ingredient in various pills.]

PROPAGATION AND CULTURE.

Theſe plants are all propagated by ſowing their ſeeds, the beſt ſeaſon for which is as ſoon as they are ripe, if they can then be procured; for when they are kept until ſpring before they are ſown, they will not come up until the ſecond year. The ground in which the ſeeds of the hardy ſorts are ſown, ſhould be freſh and light, but it ſhould not be dunged; it ſhould be well dug and levelled very even; then ſow your ſeeds thereon pretty thick, and ſift ſome earth over them about half an inch thick; this bed will require no farther care than only to keep it clear from weeds, and toward the middle or latter end of april, you will find ſome of your plants appear above ground, though, perhaps, the greateſt part of them may lie till the ſpring following before they come up; therefore you ſhould carefully clear the beds from weeds, and in very dry weather refreſh them with ſome water, which will greatly promote the growth of thoſe plants which are up, and alſo cauſe the other ſeeds to vegetate; but if the bed in which theſe are ſown is much expoſed to the ſun, it ſhould be ſhaded with mats in the day; for when the plants come firſt up, they will not bear too much heat. In this bed they ſhould remain till the next ſpring or ſecond autumn, when you muſt prepare ſome beds to tranſplant them into, which ſhould alſo be of light, freſh, undunged ſoil; and having well dug and cleanſed the ground from all noxious weeds and roots, you ſhould make it level; and then in the beginning of october, which is the proper ſeaſon for removing theſe plants, you ſhould raiſe up the young plants with a trowel, preſerving as much earth as poſſible to their roots, and plant them into beds about five or ſix inches aſunder each way, (or eighteen inches by nine or ten,) giving them ſome water to ſettle the earth to their roots; and if it ſhould prove very dry weather, you may lay a little mulch upon the ſurface of the ground round their roots, which will be of great ſervice to the plants. But as many of the ſeeds will be yet left in the ground where they are ſown, the beds ſhould not be diſturbed too much in taking up the plants; for I have known a bed ſown with theſe berries, which has ſupplied plants for three years drawing, ſome of the berries having lain ſo long in the ground before they ſprouted; therefore the ſurface of the beds ſhould be kept level, and conſtantly clean from weeds.

The plants may remain two years in theſe beds, obſerving to keep them clear from weeds; in the ſpring you ſhould ſtir the ground gently between them, that their roots may with greater eaſe ſtrike into it; after which time they ſhould be tranſplanted either into a nurſery, at the diſtance of three feet row from row, and eighteen inches aſunder in the rows, or into the places where they are to remain. The beſt ſeaſon to tranſplant them (as I before obſerved) is in the beginning of october, when you ſhould take them up carefully, to preſerve a ball of earth to their roots; and when planted, their roots ſhould be mulched; all which, if carefully attended to, as alſo obſerving to refreſh them with water in very dry weather until they have taken new root, will preſerve them from the danger of not growing; and they being extremely hardy in reſpect to cold, will defy the ſevereſt of our winters to injure them, provided they are not planted in a moiſt or rich ſoil.

In order to have theſe trees aſpire in height, their under branches ſhould be taken off, eſpecially where they are inclined to grow ſtrong, but they muſt not be kept too cloſely pruned, which would retard their growth; for all theſe Evergreen trees do more or leſs abound with a reſinous juice, which in hot weather is very apt to flow out from ſuch places as are wounded; ſo that it will not be adviſeable to take off too many branches at once, which would make ſo many wounds, from which their ſap in hot weather would flow in ſuch plenty, as to render the trees weak and unhealthy.

The Virginian Cedars grow to a very great height, and in their native country afford excellent timber for many uſes; but with us there are very few which are above twenty-five or thirty feet high, though there is no doubt of their growing larger: for they thrive very faſt after the three firſt years, and reſiſt the ſharpeſt froſt of our climate exceeding well, and are very apt to grow ſtraight and regular, provided they are not ſuffered to ſhoot out too much at bottom.

Theſe plants are alſo propagated by ſeeds, which muſt be procured from Virginia or Carolina (for they rarely produce ripe ſeeds in England) and ſown as was directed for the other Junipers; but as this ſeed cannot be procured in England till ſpring, ſo when ſown at that ſeaſon, it remains in the ground until the ſucceeding ſpring before the plants appear; therefore you muſt obſerve to keep the beds clear from weeds, and not ſuffer the ſeeds to be diſturbed, which is often the fault of ſome impatient people, who think, becauſe the plants do not riſe the firſt year, that they will never come up, and ſo dig up the ground again, whereby their ſeeds are buried; but if they are let remain, they ſeldom fail to grow, though ſometimes it is two years after ſowing before they come up. When the plants come up they muſt be carefully weeded, and in dry weather ſhould be refreſhed with water, which will greatly forward their growth; and the autumn following they ſhould have a little rotten tan laid between them, to keep out the froſt. In this bed the plants may remain till they have had two years growth, then they ſhould be tranſplanted into other beds, as was directed before for the other ſorts, obſerving to preſerve a ball of earth to their roots; and after they are planted, if the ſeaſon prove dry, they muſt be carefully watered, and the ſurface of the ground covered with mulch, to prevent the ſun and wind from entering the earth to dry the fibres; but they ſhould not be too much watered, which often proves injurious to theſe trees, by rotting their tender fibres ſoon after they are emitted, whereby the plants have been often deſtroyed.

In theſe beds they may remain two years, obſerving to keep them clear from weeds; and in winter you ſhould lay a little freſh mulch upon the ſurface of the ground round their roots, which will prevent the froſt from penetrating to them, and effectually preſerve them; for while the plants are ſo young, they are liable to be injured by hard froſts, when too much expoſed thereto; but when they have attained a greater ſtrength, they will reſiſt the ſevereſt of our cold.

After two years, they ſhould either be removed into a nurſery (as was directed for the common Juniper) or tranſplanted where they are deſigned to remain, obſerving always to take them up carefully, otherwiſe they are ſubject to fail upon tranſplanting; as alſo to mulch the ground, and water them as was before directed, until they have taken root; after which they will require no farther care, than only to keep the ground clear about their roots, and to prune up their ſide branches to make them aſpire in height.

The ſoil in which you plant theſe trees ſhould be freſh and light, but muſt not be dunged, eſpecially at the time when they are planted; for dung is very hurtful to them, if it be not quite rotted to mould; therefore the mulch which is laid upon the ſurface of the ground ſhould not be dung, but rather ſome old tanners bark or ſea-coal aſhes, which will prevent the froſt from penetrating deep in the ground.

Theſe trees being thus managed, will in a few years riſe to a conſiderable ſtature, and by the variety of their evergreen leaves and manner of growth, will greatly add to the beauty of all plantations, if rightly diſpoſed, which indeed is what we ſeldom obſerve in any of the Engliſh gardens or wilderneſſes; for there are few people who conſider the different growths of the ſeveral trees with which they compoſe ſuch plantations, ſo as to place the talleſt growing trees the backwardeſt from ſight, and the next degree to ſucceed them, and ſo gradually diminiſhing till we come to the common Juniper, and others of the ſame growth, whereby all the trees will be ſeen, and the gradual declivity of their tops will appear like a verdant ſlope, and be much more agreeable to the ſight, as alſo more advantageous to the growth of the trees, than to place ſhrubs of humble growth near ſuch plants as will grow

to the firſt magnitude, whereby the ſhrub is hid from ſight, and will be over-ſhadowed and deſtroyed: nor can the diſtance which each tree requires, be ſo juſtly proportioned any other way; for in this diſtribution, the largeſt trees being ſeparated by themſelves, may be placed at a due diſtance; and then thoſe of a middling growth ſucceeding, may be accordingly allowed ſufficient room; and the ſmaller, which are next the ſight, being placed much cloſer, will hide the naked ſtems of the larger trees, and have an agreeable effect to the ſight.

The Bermudas Cedar being a native of that iſland, and alſo of the Bahama Iſlands, being much tenderer than any of the former ſorts, except that of Jamaica, is not likely to thrive well in this country; for although many of theſe plants have lived ſeveral years in the open air in England, yet whenever a ſevere winter happens, it either kills them, or ſo much defaces them, that they do not recover their verdure in a year or two after.

Theſe plants are propagated by ſeeds in the ſame manner as the former, with only this difference, that theſe ſhould be ſown in pots or tubs of earth, that they may be removed into ſhelter in the winter time, otherwiſe the young plants are often hurt by hard froſts; but they will require no more care than only to be placed under a common hot-bed frame, where the glaſſes may be conſtantly kept off in mild weather, when they cannot have too much free air, and only covered in hard froſts. Theſe ſeeds conſtantly remain in the ground until the ſecond year before they come up, therefore the earth in the pots ſhould not be diſturbed; and in the ſummer time they ſhould be placed in the ſhade, to prevent the earth from drying too faſt: and in very dry weather they ſhould be often watered, but do not give too much water to them at once, which would rot the ſeeds.

The ſpring following, when the young plants come up, they muſt be carefully cleared from weeds, and in dry weather refreſhed with water: but ſhould ſtand, during the ſummer ſeaſon, in a place defended from ſtrong winds; and in winter muſt be placed under frames, where they may be covered in hard froſty weather, but muſt have open air when the weather is mild. In april following you ſhould tranſplant them each into a ſingle halfpenny pot filled with freſh light earth, being careful to raiſe them up with a ball of earth to their roots; and when they are planted, you ſhould water them, to ſettle the earth to their roots; then place the pots in a warm ſituation, where they may be defended from ſun and wind: but if you will beſtow a moderate hot-bed to plunge the pots in, it will greatly promote their taking new root; however, you muſt carefully defend them from the great heat of the ſun, which is injurious to them when freſh removed; but when they have taken root, you may expoſe them by degrees to the open air. If you ſuffer the pots to remain plunged all the ſummer, it will preſerve the earth therein from drying ſo faſt as it would do, if they were ſet upon the ground.

In october you ſhould again remove theſe plants into ſhelter, or elſe plunge their pots into the ground under a warm hedge, where they may be protected from the cold north and eaſt winds; and in the ſpring following you muſt ſhift the plants into pots a ſize larger, taking away ſome of the earth from the outſide of the ball, and adding ſome freſh, which will promote their growth; and ſo continue to manage them as was before directed, until you plant them out in the places where they are deſigned to remain; which ſhould not be done till they are four or five years old, by which time they will be ſtrong enough to bear the cold of our common winters.

The reaſon for my directing theſe plants to be preſerved in pots until they are planted out for good is, becauſe they are difficult to tranſplant, and being tender, will require ſome ſhelter while young; and whoever obſerves the method here laid down, will find the plants ſo managed to gain two years growth in ſix, from thoſe raiſed in the open air, and be in leſs danger of being deſtroyed; and as the trouble and expenſe in raiſing them this way is not great, it is worth practiſing, ſince in a few years the trees will recompenſe the trouble.

The timber of this tree is of a reddiſh colour, and very ſweet, and is commonly known in England by the name of Cedar Wood; though there are divers ſorts of wood called by that name, which come from very different trees, eſpecially in the Weſt Indies, where there are ſeveral trees of vaſtly different appearances and genera, which have that appellation: it is this wood which is uſed for pencils, as alſo to wainſcot rooms, and make ſtair-caſes, it enduring longer ſound than moſt other ſorts of timber, which, perhaps, may be owing to ſome extreme bitter taſte in the reſin, with which the tree abounds; for it is very remarkable, that the worms do not eat the bottoms of the veſſels built with this wood, as they do thoſe built with Oak; ſo that the veſſels built with Cedar are much preferable to thoſe built with any other ſort of timber, for the uſe of the Weſt India ſeas, but it is not fit for ſhips of war, the wood being ſo brittle as to ſplit to pieces with a cannon ball.

The Jamaica Juniper being more impatient of cold than the Bermudas, will not live through the winter in the open air in England, and the plants muſt be preſerved in pots and houſed in the winter; this is propagated by ſeeds, in the ſame way as the Bermudas Cedar; but if the pots are plunged into a moderate hot-bed the ſecond ſpring after the ſeeds are ſown, it will bring up the plants ſooner, and they will have more time to get ſtrength before winter.

All the other ſorts being hardy enough to live in the open air, are very well worth propagating, as they add to the variety of Evergeen plantations; ſome of the ſorts riſing to a very conſiderable height, may prove to be uſeful timber, and may be adapted to ſuch ſoils as will not ſuit many other trees.

The common Savin ſhould not be neglected, becauſe it is ſo very hardy as never to be injured by the ſevereſt froſt; and as this ſpreads its branches near the ground, if the plants are placed on the borders of woods, they will have a good effect in winter, by ſcreening the nakedneſs of the ground from ſight.

[The common Savin may be increaſed by ſlips, which will grow almoſt at any time. The upright Savin alſo may be propagated by ſlips planted in moiſt weather in auguſt, and kept ſhaded and watered in dry weather afterwards. The ſtriped Savin muſt be increaſed the ſame way, from the branches which are moſt variegated. They may alſo be raiſed by berries, when the plants produce any; and by theſe the moſt upright and beſt plants are produced.]

Moſt of the ſorts may be propagated by cuttings, which, if planted in autumn, (or at the end of auguſt) in a ſhady border, will take root; but thoſe plants which are raiſed from cuttings will never grow ſo upright, nor to ſo large a ſize as the plants which are raiſed from ſeeds; ſo that when theſe can be procured, it is much the better method, but the other is frequently practiſed on thoſe ſorts which do not perfect their ſeeds in England.

As ſeveral of theſe ſorts grow to the height of eighteen or twenty feet, the procuring as many of the ſorts as can be gotten from the countries of their growth, will be adding to the variety of our Evergreen plantations, which cannot be too much propagated in England, where, in general, our winters are temperate enough for them to thrive to advantage; and as the ſorts which are a little more tender than the others obtain ſtrength, they will be in leſs danger of ſuffering by ſevere winters, as we find by many other plants, which were ſo tender as not to live in the open air at firſt, but now defy the ſevereſt cold of our climate.

DESCRIPTION, *&c.*

Theſe are moſtly herbaceous plants, but ſome are ſhrubby. Leaves alternate. Flowers ſolitary, axillary[a].

1. Roots ſimple, filiform, ſhort. Stem branching, creeping. Branches long, ſubdivided, divaricating, ſomewhat ſucculent, round, ſmooth. Leaves on ſhort petioles, ſcattered, ſmall, blunt, ſpreading, entire, very ſmooth; with ſmaller ones in the axils. Peduncles ſhort, one-flowered, round, thickiſh, ſmooth. Two very minute ſcales at the baſe of the germ. Flowers yellow, ſmall. Calyx five-parted: ſegments lanceolate, the length of the petals. Petals ſubſeſſile, ovate, blunt, veined. Germ attenuated at the baſe: ſtyle thick: ſtigma convex. Capſule thickiſh, opening longitudinally. Seeds diſpoſed longitudinally in five rows, angular, compreſſed.

Native of Jamaica, in moiſt watery places, flowering in the ſpring[b]. Browne ſays it is frequent in the low lands about Plaintain-garden river.

β. The Indian plant, which ſtands as a diſtinct ſpecies in Linneus's mantiſſa, has herbaceous aſcending, ſimple, even ſtems. Leaves petioled, ovate-oblong, even, blunt. Peduncles one-flowered, ſhorter than the leaf; but thoſe of the fruit the length of the leaf.

2. Stems ſmooth, with alternate branches. Leaves quite entire.—Native of Java[c].

3. Native of Lima.

4. Stem uſually brown, ſtrong, four or five feet high, having ſeveral hairy, red, angular branches, thick ſet on every ſide with long narrow hairy nerved leaves, ſeveral of which come out together, ſome larger, ſome ſmaller: the larger three inches long, and ſcarcely one broad, light green, downy and ſoft like velvet. Flowers large, yellow, on peduncles half an inch in length, very open. Capſule large, oblong, with four or five corners, containing much ſmall yellowiſh ſeed[d].

Native of Jamaica.] Mr. Miller ſays, that the ſeeds were ſent him by Dr. Houſtoun, and that it riſes with a hairy branching ſtalk two feet high; that it has narrow ſpear-ſhaped leaves, placed alternate; that the flowers come out towards the ends of the branches ſingly from the axils and are ſeſſile; that the petals are pretty large and yellow; that the ten ſtamens ſit upon a long germ, which becomes a capſule crowned by the calyx, and filled with ſmall ſeeds.

5. This riſes with a ſhrubby ſtalk near three feet high, and ſends out ſeveral ſide branches. Leaves oblong, hairy. The flowers come out from the ſide of the ſtalks ſingly, on ſhort peduncles. Petals yellow. The capſule has a great reſemblance to Cloves.

It flowers in july and auguſt, and the ſeeds ripen in october.

[Linneus ſets it down as a native of India. Mr. Miller ſays it grows naturally at Campeachy, whence the ſeeds were ſent him by Mr. Robert Millar.

[In Linneus's mantiſſa it is ſaid that the ſtem is lofty, and alternately branched; the leaves lanceolate, ſcarcely petioled, pubeſcent as is the whole plant; the capſules a little ſhorter than the leaves, two inches long, ſtriated, ſubſeſſile: according to Gærtner, four-cornered, with prominent nerves along the middle, and ſtriated along the edges of the valves. Receptacle four-cornered-cruciate, columnar. Seeds very numerous, ovate-globular, ſlightly grooved on each ſide, ſerru-

[a] Juſſieu. [b] Swartz. [c] Burm. [d] Sloane.

ginous,

ginous, ſmooth, lucid, divided by a partition within. A bilocular ſeed in a capſular fruit is unuſual.

Gærtner remarks here that Ludwigia indeed differs ſufficiently from this genus in the fabric and ſituation of the receptacle of the ſeeds, but that the diſtinction between Juſſieua and Oenothera is merely factitious and imaginary.

6. Root annual. Stem from two to four feet high, herbaceous, very much branched, four-cornered, ſmooth, reddiſh. Branches filiform, quadrangular, erect, ſubdivided, pubeſcent. Leaves petioled, linear-lanceolate, entire, acuminate, nerved, ſmooth. Petioles very ſhort, red. Flowers abundant, yellow, ſmall. Calyx four-leaved; leaflets ovate-lanceolate, acuminate, ſpreading, ſtriated underneath, ſmooth. Petals four, diſtant, ovate, entire, concave, deciduous. Filaments eight, ſhorter than the petals, upright, contiguous to the piſtil. Anthers very minute, whitiſh, commonly glued to the ſtigma. Germ quadrangular, reddiſh, ſmooth. Style very ſhort, round and thick. Stigma ſpherical. Capſule elongated, quadrangular, retuſe, four-celled, four-valved. Seeds very minute, roundiſh, ferruginous[a].—Gærtner adds, that the capſule is ſlightly narrowed upwards and ſmooth; the partitions cohering with the angles of the receptacle and very narrow: the receptacle columnar, deeply four-grooved, with the angles compreſſed and correſponding with the partition: the ſeeds ovate, ſmooth and yellowiſh. According to Thunberg, though the perianth is commonly four-parted, yet it is ſometimes five-parted.

It is a vernal marſh plant, native of Jamaica, and others of the Weſt India iſlands, as well as of the Continent.—Mr. Miller cultivated it in 1739[b].

Thunberg found it in Japan, and alſo in Java and Ceylon; but in theſe latter places always with narrower leaves and ſubpedoncled flowers, whereas this plant has uſually leaves a quarter of an inch broad and ſeſſile flowers.

7. This is an annual plant, upright and wholly ſmooth. Stem ſimple, round, thick, porous, watery, rooting at the lower joints. Leaves obovate, blunt, petioled, ſcarcely longer than the petioles, ribbed, ſmooth. Peduncles one-flowered, a little longer than the petiole. Germ a little ſhorter than the peduncle, even, thickened, four-cornered, acute-angled. Petals four, ovate, larger, veined, very tender.

Native of Surinam, in marſhes. Found there by C. G. Dalberg[c].

8. Branches almoſt upright, four-cornered, pubeſcent. Leaves acuminate, entire, dotted underneath at the edge, nerved, pubeſcent; on ſhort petioles. Leaflets in the axils ovate, minute. Flowers on ſhort peduncles, large, yellow. Calyx ſeſſile, four-leaved: leaflets ovate-acuminate, pubeſcent. Petals four, three times as large as the calycine leaflets, diſtant, ovate or obovate, blunt, ſpreading, deciduous. Filaments eight, preſſed cloſe to the ſtyle up to the middle, the length of the piſtil, awl-ſhaped. Anthers ovate, incumbent, two-valved. Germ roundiſh-quadrangular, attenuated at the baſe, a little curved. Style thick. Stigma ſpherical. Capſule pedicelled, long, acuminate at the baſe, retuſe, four-celled, four or eight-valved. Seeds very many, roundiſh. Receptacle quadrangular.

Native of South America and the Weſt Indies, in marſhy watery places[d].

9. This is a ſhrubby plant, with a hiſpid ſtem. Branches hiſpid, alternate. Leaves ſeſſile, marked with parallel veins. Flowers large, ſeſſile, contained in a large, hiſpid, four-leaved calyx[e].

Native of South America and Jamaica.]

10. This has a branching ſmooth ſtalk near three feet high, with leaves on ſhort foot-ſtalks. Flowers ſmall and yellow.

It was ſent to Mr. Miller from Carthagena, by Dr. Houſtoun.

11. This riſes with ſingle, upright, red ſtalks three feet high, hairy and channelled. The leaves ſtand nearer together than in any of the other ſorts. Flowers axillary, towards the top of the ſtalk, compoſed of five large yellow petals. Capſules an inch long.

Sent from La Vera Cruz by Dr. Houſtoun. [His ſpecimen is in Sir Joſeph Banks's herbarium, and it is there named Juſſieua elliptica.]

[a] Swartz. [b] Hort. kew. [c] Linn. ſuppl. [d] Swartz. [e] Plumier.

PROPAGATION AND CULTURE.

All theſe ſorts are propagated by ſeeds, which ſhould be ſown early in the ſpring, in pots filled with a ſoft loamy ſoil, and plunged into a moderate hot-bed; but as theſe ſeeds often lie a whole year in the ground before they vegetate, the earth muſt be kept moiſt, and the glaſſes of the hot-bed ſhaded in the heat of the day, by this method the ſeeds may be brought ſoon to vegetate; when the plants come up, and are fit to remove, they ſhould be each planted into a ſmall ſeparate pot, filled with light loamy earth, and plunged into a hot-bed of tanners bark, where they ſhould be ſhaded from the ſun till they have taken new root; after which they ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently refreſhed with water, but it muſt not be given to them in too great plenty: when the roots of the plants have filled theſe ſmall pots, the plants ſhould be removed into others a ſize larger; and if the plants are too tall to ſtand under the frames of the hot-bed, they ſhould be removed into the bark-ſtove, where they may remain to flower and perfect their ſeeds; for when the plants riſe early in the ſpring, and are brought forward in hot-beds, all the ſorts will flower and perfect their ſeeds the ſame year, which is better than to have them to keep through the winter.

[JUSSIEUA. See *Jatropha*.]

JUSTICIA. (*So named by Houſtoun from James Juſtice, Eſq. F.R.S. one of the principal Clerks of Seſſion in Scotland, author of the Britiſh Gardener's Director*, 1764.)

Lin. gen. n. 27. *Reich.* 28. *Schreb.* 35. *Huſt. reliqu.* 1. *Gærtn. t.* 54. *Juſſ.* 104. Adhatoda. *Tournef. t.* 79.

Claſſ. 2. 1. Diandria Monogynia.

Nat. order of *Perſonatæ. Acanthi*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, very ſmall, five-parted, acute, upright, narrow.

COR. one-petalled, ringent. *Tube* gibboſe; *Border* two-lipped: *Lip ſuperior* oblong, emarginate. *Lip inferior* of the ſame length, reflex, trifid.

STAM. *Filaments* two, awl-ſhaped, hid under the upper lip. *Anthers* upright, bifid at the baſe.

PIST. *Germ* top-ſhaped. *Style* filiform, length and ſituation of the ſtamens. *Stigma* ſimple.

PER. *Capſule* oblong, obtuſe, narrowed at the baſe, two-celled, two-valved; the partition oppoſite to the valves, gaping with an elaſtic claw.

SEEDS roundiſh.

OBS. *The upper lip of the corolla differs in point of ſituation.*

Some ſpecies recede ſo much from this character as to ſeem of a diſtinct genus. Vide Maut. p. 172. *R.*

ESSENTIAL CHARACTER.

Cor. ringent. *Capſ.* two-celled, opening with an elaſtic claw. *Stam.* with a ſingle anther.

SPECIES.

* *With a double calyx.*

[1. Juſticia faſtuoſa. *Superb Juſticia.*

Lin. ſyſt. 62. *Reich.* 1. 41. *mant.* 172. *Vahl ſymb.* 1. 2. *t.* 1. & 2. 13.

Suffruticose, leaves elliptic quite entire, peduncles axillary dichotomous, upper lip upright bifid, anthers divaricating.

34. Justicia scandens.
Vahl symb. 2. 7.
Shrubby, leaves ovate acuminate subrepand, branches villose, peduncles axillary trichotomous divaricating.

35. Justicia ciliaris. *Ciliated Justicia.*
Lin. syst. 62. *suppl.* 84. *Jacqu. hort.* 2. *t.* 104. *Ait. hort. kew.* 1. 27.
Herbaceous, leaves lanceolate bluntish, flowers axillary opposite, anthers paralled appendicled.

36. Justicia secunda.
Vahl symb. 2. 7.
Herbaceous, leaves ovate-lanceolate acuminate, racemes terminating compound, racemelets pointing one way, anthers binate.

37. Justicia debilis.
Vahl symb. 2. 15.
Dianthera debilis. *Vahl symb.* 1. 5. *Forsk. descr.* 9. *n.* 23. *Dill. n.* 10.
Shrubby, spikes axillary and terminating, bractes ovate imbricate ciliate, anthers binate.

38. Justicia violacea.
Vahl symb. 2. 15.
Dianthera violacea. *Vahl symb.* 1. 6. *Dill. n.* 11.
Shrubby, leaves lanceolate, spikes terminating, bractes lanceolate imbricate, ciliate, anthers binate.

39. Justicia Rohrii.
Vahl symb. 3. 6.
Herbaceous, leaves elliptic quite entire, spikes terminating compound imbricate pubescent, bractes ovate, anthers binate.

40. Justicia polystachya.
Vahl symb. 2. 7. *t.* 26.
Herbaceous, leaves lanceolate-ovate, spikes axillary opposite pointing one way, bractes ovate hirsute, anthers binate.

41. Justicia retusa.
Vahl symb. 2. 8.
Herbaceous, leaves ovate acuminate, spikes terminating, bractes obovate subretuse imbricate, anthers binate.

42. Justicia flava.
Vahl symb. 2. 15.
Dianthera flava. *Vahl symb.* 1. 5. *Forsk. descr.* 9. *n.* 24. *Dill. n.* 9.
Shrubby, leaves lanceolate-oblong, spikes terminating, flowers in pairs, bractes lanceolate blunt.

43. Justicia americana.
Vahl symb. 2. 15.]
Dianthera americana. *Lin. spec.* 24. *Reich.* 1. 46. *Gron. virg.* 6. 5. *Dill. n.* 1.
Herbaceous, leaves linear-lanceolate, spikes axillary solitary like corymbs, peduncles filiform alternate the length of the leaves, anthers binate.

[44. Justicia punctata.
Vahl symb. 2. 15.
Dianthera punctata. *Vahl symb.* 1. 4. *Dill. n.* 7.
D. americana β. *Forsk. descr.* 9. *n.* 25.
Herbaceous, leaves lanceolate-ovate, spikes terminating, flowers remote in a sort of whorl, bractes lanceolate acuminate.

45. Justicia cristachiana.
Vahl symb. 2. 15 *Houtt. hist. nat.* 3. 46. *t.* 18. *f.* 2.
Dianthera cristachiana. *Lin. syst.* 64. *Jacqu. amer.* 4. *t.* 4. *pict.* 8. *t.* 5.
Shrubby, leaves oblong acuminate, spikes axillary and terminating, flowers in remote whorls two or three together, solitary at top, bractes wedge-shaped.

45. Justicia pectoralis.
Vahl symb. 2. 15. *Swartz prodr.* 13. *obs.* 14.
Dianthera pectoralis. *Lin. syst.* 64. *Jacqu. amer.* 3. *t.* 3. *pict.* 8. *t.* 4. *Brown. jam.* 118. *n.* 3.
Herbaceous, leaves lanceolate petioled, spikes panicled, bractes minute, upper lip undivided, anthers binate.

47. Justicia comata.
Vahl symb. 2. 15. *Swartz obs.* 14.
Dianthera comata. *Lin. syst.* 63. *Dill. n.* 2.
Herbaceous, leaves linear-lanceolate subsessile, spikes subumbelled-whorled, bractes minute, anthers binate.

48. Justicia undulata.
Vahl symb. 2. 8.
Dianthera hyssopifolia. *Burm. ind.* 11. *t.* 5. *f.* 2.
Herbaceous, leaves lanceolate waved, peduncles terminating umbelled simple and trifid, anthers binate.

49. Justicia frondosa.
Vahl symb. 2. 8.
Herbaceous, umbels axillary peduncled compound, peduncles elongated, bractes obovate rhombed smooth, blunt anthers binate.

50. Justicia pubescens.
Vahl symb. 2. 9.
Shrubby, peduncles axillary opposite four flowered pedicelled, bractes ovate-roundish mucronate pubescent, anthers binate.

51. Justicia lævigata.
Vahl symb. 2. 9.
Shrubby, peduncles axillary opposite, three-flowered pedicelled, bractes oblong mucronate pubescent, anthers binate.

52. Justicia cuspidata.
Vahl symb. 2. 9.
Dianthera verticillata. *Forsk. descr.* 9.
Peduncles axillary in whorls subtriflorous pedicelled bractes wedge-form awned, anthers binate.

53. Justicia bifora.
Vahl symb. 2. 9.
Suffruticose, peduncles axillary two-flowered pedicelled equalling the leaves, bractes awl-shaped, anthers binate.

54. Justicia sessilis.
Lin. spec. 1663. *syst.* 62. *Jacqu. amer.* 3. *t.* 2. *f.* 2. *pict.* 8. *t.* 3.
Shrubby, leaves ovate-acute subserrate, flowers axillary solitary sessile, upper lip quite entire.

55. Justicia nigricans.
Lour. cochinch. 24.
Shrubby, leaves lanceolate-linear blunt blackish, spikes distich terminating.

56. Justicia tinctoria.
Lour. cochinch. 25.
Herbaceous, leaves lanceolate subcrenate pubescent, flowers axillary heaped.]

Lin. spec. 1663. *syst.* 62. *Reich.* 1. 41. *Jacqu. amer.* 2. *t.* 2. *f.* 1. *pict.* 7. *t.* 2. *Vahl symb.* 2. 17.
Shrubby, leaves ovate or obovate, spines axillary, lateral peduncles simple, corollas salver-shaped, anthers parallel.

[73. Justicia repanda.
Forst. flor. austral. 3. *n.* 12.
Shrubby, leaves elliptic, repand, peduncle axillary trifid, corollas salver-shaped, anthers parallel.

---

74. Justicia armata.
Swartz prodr. 13.
Shrubby, prickly, leaves oblong emarginate coriaceous shining.

75. Justicia aciculatis.
Swartz prodr. 13.
Shrubby, diffused spiny, spines bristle-shaped, flowers pedunculed axillary solitary.

76. Justicia reptans.
Swartz prodr. 13.
Stem herbaceous creeping, leaves blunt, spike terminating undivided.

77. Justicia humifusa.
Swartz prodr. 14.
Stem herbaceous decumbent, leaves ovate and cordate, spikes umbelled.

78. Justicia nemorosa.
Swartz prodr. 14.
Stem herbaceous four-cornered somewhat upright, leaves ovate-lanceolate, spikes ovate.]

79. Justicia fruticosa.
Mill. dict. n. 3.
J. frutescens & hirsuta, foliis oblongis pediculis longissimis, flore rubro. *Houst. M. S. S.*
Shrubby, leaves ovate or ovate-lanceolate hirsute petioled, bractles cordate acuminate.

80. Justicia arborea.
Mill. dict. n. 7.
Adhatoda arborea, foliis oblongis subtus villosis, floribus spicatis albis. *Houst.*
Arboreous, leaves lanceolate-ovate sessile tomentose underneath, flowers in clustered terminating spikes.

DESCRIPTIONS, *&c.*

[This genus is divided by Linneus into shrubby and herbaceous, but the known species are become so numerous, and the duration of the stem is so uncertain or difficult to ascertain in plants of India cultivated in our stoves, or in specimens sent from hot countries, that Vahl has substituted other circumstances of subdivision taken from the calyx and corolla, as adopted above.

It appears from late observations of Jacquin, Jussieu, Vahl, &c. that the two anthers on each filament are not a sufficient generic distinction; for in some species of Dianthera the filaments are divided into two segments, each of which has an anther; but in others the filaments are undivided, and have two anthers indeed but so approximated as almost to coalesce into one. But not only Diantheras properly so called have two anthers, but most of the Justicias, if not all, are really Diantheras; for not only several of Linneus's Justicias have two anthers quite distinct, as J. hyssopifolia, orchioides, &c. but the rest have generally twin or double anthers, with this difference, that being parallel to each other they seem to be but one, although they are really two.

If this natural genus, consisting of Justicia and Dianthera, is to be separated, Vahl recommends it to be grounded on the capsule rather than the anthers[a].

The species in the first section might very well form a distinct genus, and accordingly were considered as such by the late Dr. Solander. Some of them rather belong to the class Didynamia and the genus Ruellia, as J. pulcherrima, infundibuliformis, gangetica, &c.

Some of the species (n. 9, 10. 31. 37, 38. 42, 43, 44. 47. 62.) are repeated from our article DIANTHERA, because they more properly belong to this place.

1. Stem round, smooth and even. Leaves opposite, petioled, quite entire, with alternate veins, hairy underneath and round the edge. Flowers very abundant, clustered in axillary racemules, not longer than the leaves. Calyx even, the size of a grain of wheat, receding in this and other parts of the flower so much as to warrant the making this plant of a genus separate from Justicia[b].

This is sufficiently distinct from the next species in its elliptic leaves narrowing to both ends, emarginate at top, usually smooth; in its compound elongated terminating raceme; in its flowers pointing one way, with roundish mucronate floral leaves; and in the four-parted outer calyxes including two flowers[c].

Native of Arabia Felix and the island of St. Johanna.

2. Branches at bottom obscurely angular, purplish, very smooth, jointed: joints three inches long marked with four lines. Leaves remote, spreading very much, quite entire, hairy on the veins beneath and about the edge, two inches long. Petiole hairy, half an inch in length. Peduncles axillary, solitary, very short, opposite, sometimes single, but more frequently bearing three subsessile spikes at top. Spikes upright, an inch

[a] Symb. 2. 11, 12. [b] Linn. mant. [c] Vahl.

in length. Flowers cluſtered, imbricate. There is an ovate petioled acute deciduous floral leaf at the baſe of each calyx. Bractæ ſolitary, linear. Scales three minute, membranaceous at the baſe of the inner calyx as in the preceding.—Native of Arabia Felix [a].

3. Stem rooting, brachiate. Leaves broad-ovate, mucronate at top and bottom, ſmooth, petioled, quite entire. Spikes on the ſides and at the tops of the branches, pointing one way. Bractæ narrow, the length of the capſules. Corollas purple; lips upright, one linear and very narrow, the other wide and three-lobed. Stamens purple, the length of the corolla [b].

Stem upright, branching, jointed, three feet high. Leaves oppoſite, ciliate about the edge. Lower lip of the corolla turbinate-oblong, very blunt. Anthers oblong [c].

Capſule ſmall, ovate-lanceolate, elongated into the peduncle tranſverſely compreſſed, opening elaſtically from the peduncle. Partition bifid. Receptacle none; but the ſeeds ſeſſile in the axils of the claws. Seed ſingle in each cell, ovate, ſlightly emarginate at the umbilicus, compreſſed a little, rugged all over with ſharp granules, of a dirty brownish red colour [d].

Found near Canton in China by Osbeck, and ſince by Loureiro.

4. Diſcovered at the Cape of Good Hope by Thunberg.

5. Branches woody, angular at top, with an excavated line running down the ſides of the joints. Leaves an inch long, quite entire, acute, villoſe eſpecially underneath, on ſhort petioles. Flowers eight or ten on each ſide, on two or three very ſhort peduncles. Bractæ of the peduncles two on each ſide, lateral, oval, narrowed at the baſe, ſemiunguicular; floral bractæ linear. Outer calyx four-parted; ſegments linear-awl-ſhaped, the two outer longer. Inner calyx five-parted; ſegments unequal, awl-ſhaped. Corolla villoſe; tube the length of the outer calyx: upper lip erect, lanceolate, entire; lower trifid, with oblong ſegments. Stamens and ſtyle the length of the corolla.

Native of the Cape of Good Hope [e].

6. Stems procumbent, hexangular, a foot long, branched at bottom. Leaves oppoſite, petioled, acuminate, bluntiſh, ſcarcely crenate, or quite entire, ſmooth. Peduncles ſometimes ſolitary, three or four-flowered at top, ſhort. Involucels two, briſtle-ſhaped, naked under each flower. Bractæ oblong, mucronate, narrowed at the baſe. Outer calyx four-leaved; leaflets lanceolate: inner five-leaved. Corolla pale violet; tube long, ſlender; border ringent, upper lip roundiſh, lower oblong.—Native of China [f].

7. Branches villoſe, with joints four inches long four-grooved. Leaves remote, quite entire, ſometimes obſcurely toothletted towards the baſe, hairy, an inch long: petiole twice the length of the leaf. Peduncles ſolitary, ſometimes oppoſite, twice or three times the length of the leaf, hairy, three or four-flowered at the top. Involucre of two petioled linear-lanceolate blunt leaflets ſhorter than the flower. Bractæ two, longer than the calyx, unequal, blunt. Outer calyx five leaved; leaflets linear, unequal: inner many-leaved; leaflets awl-ſhaped, ſhorter [g].—Native of Arabia Felix.

8. Stem filiform, having a ſhort branchlet or two at the joints, ſmooth. Leaves unguicular, often ſmaller, ſpreading very much, oblong ſometimes ſubovate, quite entire, blunt, veined, on petioles the length of the leaves. Flowers ſeſſile, alternate below, oppoſite above. Outer calyx ſemiunguicular, five-cleft; ſegments linear-lanceolate, the uppermoſt longer and broader: inner ſhort, five-parted; ſegments awl-ſhaped. It varies with rounder leaves.—Native of the iſland of Mauritius [h].

9. See Dianthera ſulcata.

10. Stem ſhrubby, angular, rough haired. Leaves oppoſite, petioled, quite entire. Panicles terminating, on trifid or bifid pedicels. Outer calyx five-cleft, the dorſal ſegment lanceolate, almoſt the length of the corolla. Flowers purple [i]. Capſule oblong, compreſſed a little, acuminate at top, elongated below into a linear compreſſed claw, by which it opens elaſtically. Seeds two in each cell, orbiculate, emarginate-beaked at the umbilicus, flattiſh on both ſides, black-brown, rugged with extremely minute headed prickles [k]. Native of the Eaſt Indies, where it was obſerved by Koenig.

11. Branches ſcarcely angular below, ſmooth, jointed: internodes two or three inches long, thicker at top and bottom. Leaves obſcurely crenate towards the baſe, with few very ſhort hairs, preſſed cloſe, two inches long, the upper ones lanceolate, cuſped. Petiole one fourth of the length of the leaf. Peduncles ſolitary, oppoſite, on the branchlets alternate, half the length of the petioles, upright, having two or three pedicels at top longer than the peduncle, and two briſtle-ſhaped leaflets the length of the pedicels. Flowers covered with two quite entire mucronate veined three-nerved unequal unguicular bractæ; the ſide-ones two-flowered, the middle one-flowered. Both calyxes equal in length, five-parted; ſegments lanceolate, villoſe. Capſule villoſe.

From Rumphius's deſcription, and from his figure, t. 22. f. 2. it is plain, that his Bungum belongs to J. purpurea, and Felium tinctorium to this. The ſynonym of Hortus Malabaricus is doubtful.

Native of the Eaſt Indies and Arabia Felix [l].

12. This is an annual plant, with an upright ſtalk, having ſix angles, riſing two or three feet high, and dividing into many branches. Leaves oppoſite, an inch and half long, and one inch broad; ſmooth, as are alſo the ſtalks. At each joint come out cluſters of ſmall bractæ. Long before the ſtalks decay moſt of the leaves fall off, leaving only theſe bractæ. Flowers in ſmall ſpikes at the ſide of the branches, ſitting very cloſe; they are of a beautiful carmine colour. The upper lip is arched, bending over the lower, which is alſo a little reflexed; both are entire. Capſules ſhort, wedge ſhaped, opening lengthwiſe, incloſing two ſmall oval ſeeds.

Native of La Vera Cruz and Jamaica. Cultivated before 1733, by Mr. Miller; whoſe ſpecimen is in Sir Joſeph Banks's herbarium.

13. Stem brittle, five or ſix feet high, ſending out many branches. Leaves two inches long, and one inch broad, hairy, oppoſite. Flowers large, of a carmine colour, and ranged on one ſide of the ſpike. Capſules ſhort, about half an inch long. It was diſcovered at La Vera Cruz by Dr. Houſtoun, [and cultivated by Mr. Miller before 1733. His ſpecimen is in Sir Joſeph Banks's herbarium.

14. This riſes by a ſlender ſtem to the height of about three feet from the ground, and ſhoots into a great number of branches that grow gradually leſs as they aſcend, and are diſpoſed in an oppoſite order, as well as the leaves from whoſe axils they commonly ſhoot [m]. It reſembles J. ſexangularis, but the bractæ are narrow and acuminate [n]. Swartz doubts whether it be really diſtinct from J. ſexangularis.—Native of Jamaica.

15. Root pubeſcent, woolly at top. Leaves radical, ſeveral, narrower at the baſe, ſubſeſſile. Scapes ſeveral, very ſimple, longer by half than the leaf, imbricate, with lanceolate acuminate appreſſed ſcales. Spike terminating, cylindrical, ſimple, imbricate, with ovate acute concave ſcales. Calyx five-parted; upper ſegment oblong, broader than the reſt; the two lower linear villoſe.

β. There is a variety with lyrate-pinnatifid leaves, and ſmooth veins, which perhaps may be a different ſpecies. There is another in Sir Joſeph Banks's herbarium, from North America, with the leaves quite entire, and ſmooth on both ſides [o].

Retzius obſerves, that the leaves are uſually lyrate, but that ſome on the ſame plant are entire.

Found in the Eaſt Indies by Koenig.

16. Stem roundiſh, compreſſed, jointed. Leaves petioled, ſmooth, acuminate, quite entire. Spike

[a] Vahl. [b] Linn. ſpec. [c] Loureiro. [d] Gærtner.
[e] Vahl. [f] Linn. ſpec. Vahl. Loureiro. [g] Vahl.

[i] Linn. ſuppl. [k] Gærtner. [l] Vahl. [m] Browne.
[n] Linn. amoen. [o] Vahl. [p] Linn. ſyſt.

ſtrobile-

ſtrobile-ſhaped; with ſpreading upright bractes. Tube of the corolla filiform, incurved, longer than the bractes; border blueiſh; upper lip very narrow, bifid at top, lower trifid, the middle ſegment broader. Anther at the bending of the upper lip[a].

Loureiro ſays it grows five feet high, upright with ſpreading branches. Mr. Miller affirms that it riſes in its native ſoil with a ſtrong woody ſtem ten or twelve feet high; that the leaves are five inches long, and two inches and a half broad, of a lucid green and oppoſite; that the flowers grow in very long ſpikes from the end of the branches, and are of a greeniſh colour with a ſhade of blue.

[Native of the Eaſt Indies, Cochinchina, &c. Cultivated in 1759, by Mr. Miller[b].

17. Stem upright, ſix feet high, round, ſcarcely branched, often ſeveral from the ſame root. Leaves ovate, acuminate at both ends, obſcurely toothletted, the upper ſurface ſmoothiſh, the lower tomentoſe, with aſcending and parallel veins, oppoſite, on ſhort petioles, eight inches long. Spikes upright, denſe, four-cornered, three inches long, moſtly in pairs or fours. Bractes roundiſh-cordate. Flowers without ſmell, in four rows, of a fine bright red.

It differs from the Juſticias in the ſtructure of the corolla and the number of ſtamens, which are four, filiform, upright, of the ſame length, inſerted into the lower part of the corolla, and nearly as long as that[c]. The younger Linnæus, in the Supplement, reckons only two ſtamens, and ſays that his plant differs from that of Jacquin in no other reſpect.

I ſhould be inclined to refer it to Ruellia; but Jacquin obſerves that it differs very much both from that and Barleria in the petals and the equality of the ſtamens. He refers it to this genus on account of the habit and the agreement of the fruit.

Native of South America, frequent near Carthagena.

18. This is an upright elegant plant, growing ſix feet high among buſhes and in hedges, but only three feet in other ſituations. It appears to be an annual plant. Stems round, ſmooth. Leaves quite entire, ſhining on the back, but ſomewhat rugged on the upper ſurface, on ſhort petioles, oppoſite, half a foot long. Bractes under each flower in threes, blunt with a little point, ſomewhat hairy on the back, upright, much longer than the calyx. Flowers void of ſcent, purple. It has altogether the character of J. euſtachiana.—Native of Carthagena in Spaniſh America[d].

19. Branches roundiſh, ſmooth, oppoſite. Leaves petioled, about a ſpan in length, much attenuated at the baſe, decurrent along the petiole, nerved, obſcurely veined, a little attenuated at the tip, ſmooth on both ſides, except along the midrib and larger veins, not at all ſoft. Spike ſolitary, ſeſſile, imbricate. Bractes brown, ſomewhat convex on the outſide, acute, concave within; the outer ones cloſely imbricate. There are two others at the baſe of each calyx, longer than the outer one, lanceolate, white tomentoſe on the outſide with very cloſe villoſe hairs, within hollow, ſmooth, pale, ſomewhat ferruginous at the tip, as are alſo the calyxes. The rachis between the flowers is alſo covered with very cloſe villoſe hairs. Calyx five-leaved; leaflets lanceolate, longer than the bracte, ſtriated, very ſmooth, the two inmoſt narrower. Upper lip of the corolla bifid: ſegments linear-lanceolate; lower lip undivided, lanceolate. Filaments a little ſhorter than the corolla: anthers parallel. Germ oblong.

It was ſent from Cayenne by von Rohr as J. pulcherrima of Jacquin, with which it agrees in the leaf and corolla; but the leaves are not ſoft to the touch underneath, the ſpikes are terminating and ſolitary; not axillary two or four together, the bractes ovate not ſubcordate-round, the anthers ſmall and ſmooth, not very large and villoſe at the back; nor has von Rohr mentioned any thing of the inner bractes and rachis being tomentoſe. It differs from J. pulcherrima of Linneus in the ſmoothneſs of the branches, and in the leaves not being hoary with ſoft hairs underneath, nor quite entire. It is certainly different from J. pulcherrima of Vahl's ſecond part[e].

[a] Linn. ſyſt. [b] Hort. kew. [c] Jacquin. [d] Ibid. [e] Vahl.

20. Stem ſix feet high, nearly erect, round, covered by a ſmooth brown bark, cracking longitudinally. Branches erect, leafy, ſwelled at the inſertion of the leaves; the younger ones ſlightly quadrangular, ſmooth. Leaves about the tops of the branches, oppoſite, ſpreading but a little deflexed, entire, waved, veiny, dull green, ſmooth, veins alternate: foot-ſtalks ſhort, roundiſh. Spikes terminating, moſtly ſolitary, erect, ſimple, denſe, many-flowered; at length appearing lateral from the growing out of young branches. Common flower ſtalk reſembling the branch, roundiſh. Larger bractes nearly alternate, ſhaped like the leaves, but much ſmaller, nearly erect, ſlightly downy, one to each flower; ſmaller ones two together above each of the larger, minute, linear, acute, ſcarcely perceptible in the upper part of the ſpike. Flowers ſeſſile, one between each pair of the ſmaller bractes, erect, large, handſome, ſcarlet becoming tawny in decay. Segments of the calyx inflexed and ſlightly downy. Corolla an inch and half long, incurved, angular; the angles ſlightly downy; the limb four-cleft; its upper ſegment broadeſt, recurved at the tip, notched; three lower ones equal, linear-oblong, obtuſe, entire, pendulous. Filaments inſerted into the baſe of the corolla before, ſcarcely ſo long as the limb, a little incurved, ſimple, linear, angulated, downy, tawny. Anthers linear, obtuſe, cloven at the baſe, incumbent, tawny. Germ ſuperior, ſtanding on a white fleſhy receptacle, ovate, compreſſed, furrowed on the edges, green, very ſmooth. Style a little longer than the ſtamens. Stigma minute, cloven.

This is the largeſt ſpecies, at leaſt of thoſe that are cultivated here, and grows in the hot-houſe almoſt to the ſize of a tree. The flowers are only to be found on old plants. The leaves, when bruiſed, have an herbaceous ſmell, like ſome trefoils; the flowers have no ſmell.

Native of South America. Found by Aublet on the banks of rivers in the iſland of Cayenne, flowering in October, november, and december. Here it flowers in ſummer[a]. Introduced about 1770[b].

21. Branches obſcurely quadrangular, pubeſcent, with internodes three inches long. Leaves petioled, an inch long, remote, blunt, ending at the baſe in a ſhort petiole, bluntly and remotely toothed, with minute hairs preſſed cloſe on both ſides, whiter underneath. Spikes pedunculed, oppoſite or alternate, an inch long: peduncles longer than the leaves, often two-leaved; leaflets lanceolate, with the rudiment of a flower in the axils. The lower bractes ovate-lanceolate, with three or four toothlets on each ſide: the reſt ovate, quite entire; all hirſute eſpecially at the edge. Flowers oppoſite, with two briſtle-ſhaped bractes at the baſe. Segments of the calyx linear-lanceolate, hirſute.—Found in Java, by Thouin[c].

22. Branches round. Leaves on very ſhort petioles, two inches long, ovate, acute, quite entire, ſmooth. Spikes from the upper axils, a pair on each ſide, oppoſite, on very ſhort peduncles, two inches long, upright. The loweſt flowers oppoſite, the reſt alternate. Bractes from upright ſpreading, three to each flower, permanent, half an inch long, narrow. Calyx five-parted; ſegments linear awl-ſhaped, ſhorter by half than the bractes. Capſules pubeſcent, the length of the bractes.

Native of the Caribbee iſlands[d].

23. Stem ſmooth, round. Leaves on very ſhort petioles, two inches long, quite entire, ſmooth, bluntiſh, with ſimple veins. Spikes from the end of the branches, a hand in length. Flowers two or four on each ſide. Bractes briſtle-ſhaped. Under each whorl a linear-lanceolate leaflet on each ſide, on a ſhort petiole, the length of the flowers, the upper leaflets ſmaller. Segments of the calyx briſtle-ſhaped. Corolla yellow. Style the length of the corolla[e].

Native of the Eaſt Indies.

24. This varies with ſhorter denſer hairy ſpikes, figured by Plukenet in t. 392. f. 4; and with longer narrower ſmooth ſpikes, figured by the ſame author in t. 56. f. 3; with ſmaller rounder leaves, the ſtems branch-

[a] Smith. [b] Hort. kew. [c] Vahl. [d] Ibid. [e] Ibid.

ing

ing very much and diffuſed, the ſtem more upright, or the leaves lanceolate [a].

Burman ſays that his ſpecimens agree with hort. malab. 10. t. 94. and Pluk. phyt. t. 392. f. 4. (in which the ſpikes are longer) in figure, more ovate leaves, and ſeſſile imbricate ſhorter incraſſated ſpikes. Native of Ceylon and Java.

25. Leaves oppoſite. Racemes (ſpikes) ſimple, from each axil, the length of the leaves, ſpreading. Flowers ſeſſile, remote, upright. Calyxes briſtle-ſhaped, long [f]. Native of the Eaſt Indies.

26. Stem ſmooth. Leaves three or four inches long, ſcarcely an inch in breadth, attenuated, blunt, quite entire, ſmooth. Petiole linear, filiform, an inch long. Spikes double the length of the petiole. Flowers alternate. Bractes two at the baſe of the calyx; one ſmaller, the other the ſame length with the calyx, covering the flower; both lanceolate, acuminate. Segments of the calyx briſtle-ſhaped. Corolla ſmall, twice the length of the calyx.—Native of the iſland of Mahé. Thouin [g].

27. Branches round, ſmooth. Leaves three inches long, broad-ovate, ſmooth, quite entire, on a petiole only two lines in length, channelled above, convex underneath. Peduncle terminating, upright, often a foot long, with two oppoſite branches at bottom, a ſpan long and ſimple. Flowers below two or three on each ſide, ſolitary above; the lower ones more remote. Bractes two, awl-ſhaped, ſhorter than the calyx. Segments of the calyx five, briſtle-ſhaped, ſcarcely villoſe. Tube of the corolla narrow, three times the length of the calyx. Capſules ſomewhat hairy. It approaches to Rheed. malab. 9. 83. t. 44. and perhaps is not different, but the flowers are ſmaller in Koenig's ſpecimens.—Native of the Eaſt Indies [h].

28. Stem ſtriated, eight feet high, the thickneſs of the human arm; with aſcending, whitiſh, even, brittle branches. Leaves quite entire, ſhining, petioled, oppoſite, duſky green, beautifully marked with a long, white, lucid, ſinuated ſpot in the middle, whence the trivial name; the lateral ribs are parallel and oblique. Flowers in ſhort ſpikes. Calyx five-cleft, acute, ſhort, permanent. Corolla red; border oblong; mouth inflated; upper lip curved in, emarginate; lower ſpreading, trifid, equal:—according to Loureiro, upper lip concave, quite entire, lower bifid. Stamens ſtraight, under the upper lip. Anthers incumbent [i]. Bractes minute, ovate [k].—Native of the Eaſt Indies.

29. Branches obſcurely quadrangular, very ſmooth, aſh-coloured, alternately compreſſed at the tip. Leaves often a ſpan long, quite entire, veined, very ſmooth, on ſhort petioles. Peduncle terminating, compreſſed, a ſpan long; at the baſe often two branches, oppoſite, ſpreading. Pedicels ſeveral, three or five on each ſide, aggregate, oppoſite, filiform, diſtant: bractes minute, awl ſhaped at the baſe. Calyx ſmooth, minute, five-cleft, with briſtle-ſhaped ſegments. Upper lip of the corolla bifid, with lanceolate ſegments; lower trifid, more deeply cut. Filaments only half the length of the corolla. Anthers ſimple. It has the habit of J. variegata, Aubl. guian. t. 4. which differs however in having ſeſſile leaves, flowers in ſpikes, peduncles and calyxes rough-haired [l].

Jacquin ſays, that it very much reſembles J. hirſuta; and that beſides the two fertile ſtamens, there are at the bottom of the corolla two barren filaments, which Vahl could not diſcover.

Native of the Weſt Indies; Martinico, Guadaloupe, and S. Cruz.

30. Stem ſmooth, quadrangular; angles acute, with a groove on each ſide; the internodes two inches long. Branchlets axillary, a little longer than the petiole, flower-bearing. Leaves an inch and more in length, ſpreading, quite entire, acuminate, running a little down the petiole, ſmooth above, paler underneath, veined: petiole ſhorter by half than the leaves. Peduncles from the axils of the leaves on the branchlets, oppoſite, filiform, two-parted, ſpreading very much, one-third of the length of the leaves: pedicels oppoſite, upright: bracte linear the length of the pedicel at the baſe of each pedicel, and two at the baſe of the diviſion of the peduncle. Flowers ſmall: a linear leaflet, a little dilated at the tip and below, covering the calyx at the baſe half way. Calyx deeply five-cleft, a little ſhorter than the bracte; ſegments briſtle-ſhaped, rough-haired, as are alſo the pedicels, the ſame length with the tube of the corolla; the lower lip of which is three-toothed. Anthers ſimple.

It differs from the next ſpecies, to which it approaches in habit, by a ſtem three times the thickneſs, longitudinally grooved, broader leaves on long petioles, peduncles three times ſhorter than the leaves, once bifid, flowers oppoſite longer than the calyxes and bracted at the baſe, and ſmooth filaments.—Native of Malabar. Koenig [m].

31. Stem a foot and half high, ſtiff, four-cornered; angles ſharp, ſmooth, with two ſtreaks at the ſides. Leaves like thoſe of J. pectoralis, an inch and half long, attenuated to both ends, ending in a very ſhort petiole, quite entire, ſmooth, bluntiſh. Peduncles quadrangular, ſmooth, ſpreading very much: the axillary one ſolitary, oppoſite, moſtly bifid, ſomewhat branched: the terminating one panicle-branched: partial peduncles oppoſite. Pedicels alternate, remote, capillary, ſolitary but frequently with the rudiment of a ſecond in the axils of the bractes. Bractes oppoſite, thoſe under the firſt ramifications linear-lanceolate; at the baſe of the pedicels awl-ſhaped and very ſhort; at the baſe of the calyx none. Calycine ſegments awl-ſhaped, nearly equal, pubeſcent. Corolla pubeſcent on the outſide: upper lip bifid, linear, blunt: lower trifid, with lanceolate ſegments. Filaments extremely hirſute longitudinally, almoſt as long as the corolla. Anthers ſimple. Capſule ſcarcely an inch long, linear, margined, ſharp at both ends, mucronate, ſhining yellow with a purple line along the middle.—It differs from the other ſpecies, in having capſules compreſſed flat and of the ſame breadth from end to end.—Native of the Eaſt Indies [n].

32. Stem roundiſh, ſmooth, very finely ſtriated. Branches alternate. Leaves on very ſhort petioles, an inch or more in length, attenuated, thinly hairy, ſpreading very much, remotely toothed, veined; veins alternate, ſimple: the upper leaves lanceolate, quite entire. Racemes pubeſcent. Pedicels ſhort. One bracte at the baſe of the pedicels, and two under each flower. Calyx deeply five-cleft: ſegments linear-lanceolate, one-third of the length of the corolla. Lips of the corolla divaricating: upper narrower, two-toothed; lower trifid, with lanceolate ſegments: the lips have changed places. Stamens in the lower lip, the length of the corolla. Anthers ſimple.—Native of Java. Thouin [o].

33. Stem ſhrubby, ſomewhat angular, three feet or more in height, green, very much branched, ſlightly pubeſcent. Leaves oppoſite, on ſhort footſtalks, running out to a blunt point, veiny, a little downy. Peduncles alternate, with two ſmall bractes at each diviſion. Flowers pure white inodorous. Calycine leaflets lanceolate, entire, permanent. Theſe, as well as the whole of the plant are beſet with minute, tranſparent globules, viſible with a magnifier. Corolla deciduous; tube linear, grooved, pale green, ſlightly villoſe, bending a little upwards; upper lip very narrow, bent back, the edges towards the baſe rolled back, ſo as to make it appear in that part almoſt tubular; lower lip hanging down, trifid; ſegments equal, obtuſe at the baſe, round; the mouth marked with fine purple dots. Filaments ſhort, projecting from the mouth of the tube, finally bending back. Anthers at firſt yellow, afterwards livid. Germ oblong, ſmooth. Style capillary, ſlightly hairy. Stigma bifid. It produces almoſt the year through abundance of flowers, diſtinguiſhed not leſs for their ſingularity than their ſnowy whiteneſs. The bruiſed leaves are uſed in the Eaſt Indies, where it is a native, for the cure of cutaneous eruptions. Introduced into the Royal Garden at Kew ſince the publication of the Catalogue in 1789 [p].

[a] Vahl. [b] Ibid. [c] Vahl. [d] Ibid. [e] Linn. zeyl. [f] Linn. Loureiro. [g] Vahl. [h] Ibid. [i] Vahl. [k] Ibid. [l] Vahl. [m] Ibid. [n] Ibid. [o] Curtis.

34. Branches climbing, round, villose, jointed. Leaves two inches long, broad-ovate, sharp at the base, veined: veins somewhat villose on both sides. Petioles villose, subcinereous. Peduncles opposite, half the length of the leaf, first three-parted, then once bifid. Pedicels two-flowered. Bractes two, opposite, very minute, bristle-shaped, at the base of the pedicels and calyx. Calycine segments bristle-shaped.—It varies with the branches, and veins of the leaves less villose, and is allied to *J. nasuta*. Native of Malabar. Koenig [t].

35. Stem dividing from the very bottom into long branches, resembling so many stems: these are round at bottom, but obscurely quadrangular at top, upright, weak, hairy, a foot and half high, a little branched at top. Leaves opposite, hirsute, on a ciliate petiole, quite entire, dark green on the upper surface, spreading, the lower ones remote, the upper closely and imbricately heaped, and hence having the appearance of a quadrangular spike. Flowers solitary, sessile, small, inodorous, in all the axils of the leaves. Bractæ one on each side of every flower, sublinear, green, ciliate with long white hairs. Calycine leaflets like the bractes, but shorter by half. Tube of the corolla shorter than the calyx, gibbose, whitish: lower lip twice as long as the tube, flat, and spreading very much, ending in a wide and equally trifid border, wholly white, except two little sulphureous knobs at the origin, with two fulvous dots before them: upper lip ovate, two-toothed, shorter, concave, upright, brownish on both sides, with longitudinal yellow streaks. In this lip the stamens are placed. Each anther divides at bottom into two legs, the inner of which is shorter and free, the outer ends in an inflexed filament. Style awl-shaped. Stigma bifid. Capsule compressed, orbiculate, acuminate both ways, smooth, brown; containing in each cell one kidney-shaped, dark, compressed seed, appearing as if it were dusty, placed transversely, having at top and bottom a tuft of brownish hairs, which in the magnifier appear round, awl-shaped, pellucid, and divided into several chambers by transverse partitions. The whole plant is rugged. It flowers the whole summer. Its native place of growth is unknown [u].—Introduced in 1780, by Monf. Thouin [x].

36. Stem upright, very smooth, as is the whole plant, hexangular with the sides grooved. Leaves petioled, two inches long, attenuated, quite entire. Raceme a hand in length, upright, composed almost to the top of upright racemelets, an inch long, opposite; towards the top simple, with opposite flowers. Flowers on the racemelets alternate, four or five, on short pedicels. Bractes two, bristle-shaped, the length of the pedicel, and at the base of the pedicels. Calycine segments linear-lanceolate. Corolla purple, bifid; upper lip linear, entire; lower subtrifid. Filaments capillary, the length of the corolla. Anthers two, pedicelled. Style the length of the corolla, capillary.—Native of the island of Trinidad: von Rohr [y].

37. See Dianthera debilis.

38. See Dianthera violacea.

39. Stem upright, branched, quadrangular, very finely pubescent at top, somewhat hoary. Leaves six or eight inches long, and two or three broad, attenuated, sharp at both ends, nerved, smooth, on petioles two inches long. Partial spikes on short peduncles, opposite. Peduncles pubescent. Flowers opposite. Bractes in pairs, pubescent the length of the calyx. Calycine leaflets linear-lanceolate, pubescent. Upper lip of the corolla linear-lanceolate, undivided; lower trifid. Filaments undivided. Anthers two on each filament, one placed a little above the other. Native of Cayenne. Von Rohr [z].

40. Stem upright, stiff, obscurely quadrangular, hairy backwards at the angles. Leaves three inches long, attenuated, sharp, quite entire, smooth above, shining, hairy underneath, spreading very much, on very short petioles. Spikes solitary, upright, shorter by half than the leaf, imbricate, axillary, with one terminating. Anterior bractes ovate, membranaceous, neryed, hairy-ciliate; the dorsal ones half-ovate, ciliate, cuspid, one at the base of each flower. Flower solitary, sessile, in the axils of the bractes. Calycine segments bristle-shaped. Filaments bifid at the tip, one segment upright, the other bent down; with a single anther on each segment. Native of Cayenne. Von Rohr [a].

41. Stem round, smooth, as is the whole plant. Leaves on short petioles, two inches and more in length, with raised nerves on both sides, quite entire, blunt-ish, paler underneath. Peduncle simple, three or four inches long, flowering at top, in a spike an inch long: flowers solitary, opposite. Bractes three to each flower; the outer much broader, narrowed at the base, obovate; the two side ones oblong, attenuated at the base, shorter than the outer, subciliate, with minute hairs. Calycine segments lanceolate. Corolla large, purple, cloven beyond the middle: upper lip lanceolate, two-toothed, shorter than the lower; which is three times broader, and trifid; the segments oblong. Stamens the length of the upper lip. Native of the island of Santa Cruz in America. Pflug [b].

42. See Dianthera flava.

43. See Dianthera americana. Mr. Miller's specimen is in the Banksian herbarium.

44. See Dianthera punctata.

45. This is an upright shrub three feet high, with round bristle stems. Leaves quite entire, smooth, on short petioles, opposite, three inches long. Common peduncles racemed, little divided; the terminating many-flowered, the axillary three-flowered or thereabouts. Bractes usually in threes, shorter than the calyx. Flowers inodorous, purple. Capsules wedge-shaped [c].

According to Vahl, there are frequently two or three flowers within a six-leaved involucre; the two outer leaflets larger, widening outwards, mucronate, one a little shorter than the other, the remaining four equal and awl-shaped.

Native of the West-Indies; common on the arid open hills of St. Eustatia.

46. This is an upright plant, two or three feet in height. (Browne says, it seldom rises more than ten or twelve inches.) Probably it is annual. Leaves acuminate, two inches long. Panicles terminating, dichotomous, slender. Flowers numerous, red, sessile. Bractes bristle-shaped. The whole plant has the smell of new hay mixt with a refreshing aromatic scent.

Native of the West Indies; (Domingo and Martinico) where the inhabitants make a syrup of it, which they use against disorders of the breast. The bruised leaves are also good in wounds and cuts; whence the French there call it *Herbe à charpentiere* [d].

47. See Dianthera comata.

48. Branches a foot long and more, quite simple, opposite, from upright spreading, obscurely angular, with internodes from three to four inches in length; there are frequently two other shorter branches from the axils. Leaves two inches long, very remote, acuminate, somewhat rugged, paler underneath, on filiform petioles two or three lines in length. Peduncles at the ends of the branches, from the axils of the terminating leaves, three or five, equal, broader at top; the lateral ones trifid, the middle ones undivided. Bractes at the base, bristle-shaped. Besides these, there are two lanceolate acuminate leaflets, one shorter than the other, protecting two or three flowers. Calycine segments bristle-shaped. Capsules villose. Observed in Malabar by Koenig [e].

49. Stem round, smooth. Leaves two inches long, ovate, acute, smooth, quite entire, on short petioles. Common peduncles opposite, three times as long as the leaf, quadrangular, pubescent at top, with sharp angles: partial peduncles umbelled, four, an inch long, pubescent, the middle ones a little longer. Pedicels three or four, very short, umbelled. Bractes of the peduncles and pedicels in pairs, opposite, oblong, acuminate—of the flowers rhomb-shaped, blunt, membranaceous, veined, much larger than the calyx,

[t] Vahl. [u] Jacquin. [x] Hort. kew. [y] Vahl. [z] Ibid. [a] Ibid. [b] Vahl. [c] Jacquin. [d] Ibid.

one

one ſmaller—of the calyxes linear, awl-ſhaped, the length of the calyx, which is ſmall and pubeſcent. Corolla longer than the bractes, pubeſcent on the outſide, with the lower lip three-toothed. Stamens ſhorter than the corolla. Native of Otaheite [e].

50. Stem branched, pubeſcent, round. Leaves petioled, two inches long, ovate-lanceolate, bluntiſh, quite entire, the younger ones pubeſcent. Peduncles ſhorter than the petiole, with four nearly equal pedicels at top. Bractes four under the umbel, awl-ſhaped, ſpreading very much, a little reflex at the tip. Calyx and floral bractes as in the preceding, only mucronate and pubeſcent, the two middle ones larger, as in the other ſpecies allied to it. Capſule pubeſcent. Native of Botany Iſland. Fabricius [f].

51. Stem covered with an aſh-coloured bark except at top, where it is green. Branchlets quadrangular, oppoſite, ſhort, ſpreading very much. Leaves petioled, an inch long, ovate, attenuated, quite entire, bluntiſh, ſmooth on both ſides. Peduncles ſolitary, ſhort, pubeſcent, with three one-flowered pedicels at top, double the length of the peduncle, a little dilated at top, the middle one a little longer. Bractes of the peduncle four at the ſides, awl-ſhaped, ſpreading very much, reflex: floral bractes oblong, parallel, one ſmaller: calycine bractes lanceolate. Calyx as in the preceding. Corolla pubeſcent, half as long again as the bractes.—This is very nearly allied to the two ſpecies immediately preceding. Native of Java.—Thouin [g].

52. This reſembles J. chinenſis ſo much, that it may be conſidered as a mere variety. It differs only in the form of the bractes, and the number of the anthers [h].

Forſkahl deſcribes the leaves as lanceolate-ovate and entire; the flowers as ſeſſile, in heads, violet-coloured, whorled; with obovate-lanceolate, ciliate, mucronate bractes, bigger than the calyx; the whorls peduncled.

53. Branches obſcurely quadrangular, ſmooth; with internodes three inches long, ſomewhat gibboſe on one ſide at the baſe. Leaves an inch long, ovate, a little attenuated, ſharp at the baſe, very ſmooth; on looſe petioles, the lower ones the length of the leaves. Pedicels unequal. Bractes two at the baſe of the pedicels, petioled, oblong, acute: floral bractes three under each calyx, unequal; two awl-ſhaped, the third ovate. Native of the Eaſt Indies. Schumacher [i].

54. This is an upright plant, with ſlender round branches. Leaves oppoſite, on ſhort petioles. Floral bractes acute, ſmall, commonly two to each flower. Flowers inodorous, purple. Native of the Weſt-Indies; frequent in the iſland of St. Euſtatia in hedges and coppices; flowering in july and auguſt [k].

55. Stem upright, ſix feet high. Leaves quite entire, thick, ſubſeſſile, oppoſite. Branches and leaves marked with black lines. Corolla white, variegated with red: upper lip lanceolate, entire, upright; lower trifid, reflex. Bractes briſtle-ſhaped. Native of Cochinchina.

56. Stem branched, procumbent, long, round, grooved. Leaves acuminate, oppoſite. Bractes conical, bluntiſh. Peduncles one-flowered, many together. Corolla roſe-coloured; both lips reflexed: the upper ovate, quite entire; the lower oblong, blunt, trifid. The leaves dye cloth of a fine green colour. Native of Cochinchina [k].

Loureiro has another ſpecies, which he ſuſpects may be the *faſtuoſa* of Linneus; but it can ſcarcely be the ſame, ſince he deſcribes the leaves as ellipdic and ſubſerrate; the flowers in compound raceines or thyrſes; the upper lip of the corolla acute, and the lower trifid: whereas in the *faſtuoſa* the leaves are ſharp at both ends, and quite entire; the flowers all point one way; the upper lip of the corolla is blunt, and the lower entire.]

57. Malabar Nut riſes here with a ſtrong woody ſtem to the height of twelve or fourteen feet, ſending out many ſpreading branches. Leaves more than ſix inches long, and three inches broad, placed oppoſite. Flowers on ſhort ſpikes at the end of the branches. Corolla white, with ſome dark ſpots. It flowers in july, but does not bear ſeeds in England. Native of Ceylon. [Cultivated in 1699, by the Dutcheſs of Beaufort. It flowers in may and july [l]. Mr. Miller's ſpecimen is in the Bankſian herbarium.

58. Stem nearly as in Adhatoda and Ecbolium, but more herbaceous. Leaves ſmaller, more remote, lanceolate-ovate. Bractes waved, oppoſite, ovate, acuminate, netted-veined, coloured. Upper lip of the corolla broad, as in the preceding ſpecies, but the lower lip differently conſtructed. Native of the Eaſt-Indies.

59. This plant has the appearance of Thymus Acinos. In Herman's ſpecimen the leaves are much broader than in Burman's figure (which is not our plant), ovate and crenulate. Stems procumbent, putting out roots from the joints. Spikes with lanceolate bractes, by no means membranaceous at the edge [m].—In the ſpecies it is ſaid that the bractes are widely membranaceous at both edges—and in the ſyſtema, that it varies with lanceolate, ſeſſile leaves. Native of Ceylon.

60. The herb has the appearance of J. repens. Branches oppoſite, long, diffuſed. Leaves oppoſite, quite entire, even, petioled. Spikes ſolitary, with very ſmall flowers, underneath longitudinally imbricate in a double row [n]. Native of the Eaſt Indies. Koenig ſent it from Calcutta, and it is thus deſcribed by Retzius under the name of J. parviflora.

Stems ſubherbaceous, diffuſed, angular, pubeſcent. Leaves ovate, quite entire, acute, ſomewhat hiſpid. Spikes half an inch long, terminating and axillary, peduncled, pointing one way, many-flowered. Dorſal bractes imbricate, lanceolate, acuminate, green, obliquely nerved, with a thin white margin: the anterior ones like theſe, but winged as it were with a wider margin, ſomewhat hirſute within: the upper ones emarginate. Calyx minute, hyaline, with ſharp teeth. Corolla minute, white, with a green upper lip.

Vahl remarks, that the ſpikes are ſeſſile, as in the preceding, and the dorſal bractes lanceolate; whereas in repens they are ovate.

61. The whole plant is of a blood-red colour, whence its trivial name. Stem ſimple, the lower internodes two inches, the upper ſcarcely half an inch in length. Leaves an inch long, uſually quite entire, but ſometimes obſcurely crenate, blunt, ſmooth, on petioles twice or three times as long as the leaf. Peduncles imbricate at top, with ſix minute, briſtle-ſhaped, oppoſite ſcales. Calycine ſegments briſtle-ſhaped, longer than the tube of the corolla, which is ſhort: upper diviſion of the corolla oblong, emarginate; lower twice as broad, the length of the upper, ſubtrifid, the ſegments lanceolate. Found in Ceylon by Koenig [o].

62. See Dianthera japonica.

63. This is a ſtiff ſhrub, with oppoſite, diſtorted, warted, round branches, quadrangular at top, with an aſh-coloured pubeſcent bark, leafleſs at bottom. Leaves petioled, an inch long, approximating, quite entire, coriaceous, veinleſs, nerved; when young ſomewhat aſh-coloured. Peduncles only half the length of the petiole, ſolitary, two or three-flowered. A bractle on each ſide at the top of the petiole, lanceolate, longer than the calyx; another at the baſe of each flower, ovate, aſh-coloured, ſhorter than the calyx. Calycine ſegments lanceolate, ſubvilloſe. Corolla an inch and half in diameter, with equal lips; the upper lanceolate, blunt, entire; the lower trifid, with linear ſegments. Stamens the length of the corolla. Style longer [p]. Native of Arabia Felix.]

64. Stem from three to four feet high, ſending out branches on every ſide from the bottom, ſo as to form a pyramid; they are covered with a white bark. Leaves entire, near two inches long, and one third of an inch broad, ſmooth, ſtiff, deep green, oppoſite: at the baſe of the foot-ſtalks come out cluſters of ſmaller leaves, of the ſame ſhape and texture. Peduncles ſhort.

[a] Vahl. [b] Ibid. [c] Ibid. [d] Jacquin. [e] Ibid. [f] Loureiro.

[g] Hort. kew. [h] Linn. zeyl. [i] Linn. amoen. [k] Vahl. [l] Ibid.

Flowers

Flowers white, with long calyxes. Capſules oblong, when ripe throwing out their ſeeds, whence its name of Snap-tree. Native of the Canary iſlands, whence the ſeeds were brought about the year 1690, and cultivated in the royal garden at Hampton Court.

[65. This is a very ſtiff ſmooth ſhrub. Leaves ſmall, extremely ſtiff, almoſt prickly at the end. Found at the Cape of Good Hope by Thunberg [r], and Maſſon. Introduced in 1774. It flowers in auguſt and ſeptember [s].

66. Stem ſolid, round, ſmooth, whitiſh. Leaves oppoſite, ſubpetioled, ſmooth, blunt, either emarginate or acuminate at the tip. Bractes in pairs, deciduous. Flowers few. Capſule oblong, narrowed at the baſe, ſharpiſh. Native of Madura [t].

67. This is a ſtiff ſhrub, with an aſh-coloured bark. Branches and branchlets oppoſite, ſpreading, angular, jointed, with a ſmall tubercle on each ſide at the top of every joint. Leaves ſeſſile, thick, with veins underneath, but none above, quite entire. Flowers alternate, with two linear bractes at the baſe, the length of the calyx. Calycine ſegments linear-lanceolate. Corolla like that of J. hyſſopifolia: anthers one above the other as in that, the lower having at the baſe a white awn bent in at the tip. Native of the Cape of Good Hope. Dahl [v].

68. Stem round, red, covered with ſlender, white, ſoft hairs. Leaves ſomewhat fleſhy, petioled, waved, ſmall. Spikes terminating; with oppoſite obcordate bractes, preſſed cloſe, with ſolitary flowers in their axils. Found in Tranquebar by Koenig [w].

69. Stem aſh-coloured. Branches obſcurely quadrangular, four-grooved. Leaves petioled, coriaceous, veinleſs, mucronate [x].

Native of Arabia Felix, where they make wreaths of it to wear on their heads on feſtivals. It has little ſmell when green; but dry it ſmells like Anthoxanthum or Vernal-graſs [y].

70. Branches round. Leaves quite entire, ſmooth, on long petioles. Peduncles at each joint of the ſtem ſolitary, the length of the leaf, even. Spike oblong, imbricate, in two rows; with lanceolate, ciliate bractes; between which are four ſmaller linear bractes. Calyx hairy at top. Corolla handſome, white; with a filiform tube, incloſing the ſtamens, and a border the ſize of Narciſſus poeticus, with five ſpreading lobes, the loweſt of which is larger than the reſt. Native of the Eaſt Indies [z]. This is probably rather a ſpecies of Ruellia.

71. Branches angular, with a ſmooth aſh-coloured bark. Leaves petioled, three inches and more in length, very ſmooth, attenuated to both ends; ſegments remote, alternate, rounded [a]. Native of the iſland of Tanna [b].

72. Stem five feet in height, dividing into few, round, weak, pliant, leafy, very long branches. Leaves quite entire, blunt, ſhining, oppoſite, about half an inch in length. It is armed with ſtrong, oppoſite, very ſpreading, awl-ſhaped, acuminate ſpines, half the length of the leaves. Between the leaves and ſpines come out the peduncles, three or four together, one-flowered, ſhort, oppoſite. Flowers inodorous, ſhorter than an inch, purple. Native of the Weſt Indies; about Port au Prince in Domingo [c], and Jamaica. Vahl remarks, that there are frequently ſeveral leaves from the ſame gem; and that it varies with oblong, obovate, roundiſh, emarginate, greater and ſmaller leaves.]

Mr. Miller adds, that the branches are covered with a whitiſh bark; that under the leaves at every joint there are two ſharp thorns like thoſe of the Barberry; that the flowers which come out ſingly from the axils, are ſmall, and of a pale red colour. Dr. Houſtoun ſent it from Jamaica to England, [and therefore Mr. Miller cultivated it before 1733, in which year Dr. Houſtoun died. His ſpecimen is in the Bankſian herbarium.

73. Native of the iſland of Tanna in the South Seas [d]. Diſcovered there the 13th of auguſt 1774 [e].

74. 75. Natives of Jamaica.

76. Annual. Native of St. Domingo.

77. Annual. Native of Jamaica.

78. Perennial. Native of Jamaica and Hiſpaniola [f].]

79. This riſes with a hairy ſhrubby ſtem four or five feet high, dividing into ſeveral branches. Leaves four inches long, and two inches and a half broad, oppoſite, on foot-ſtalks above an inch long; at the baſe of theſe come out a cluſter of ſmall leaves. Flowers in looſe cluſters from the axils towards the end of the branches, of a pale red colour.

Diſcovered by Dr. Houſtoun at Campeachy. [Cultivated by Mr. Miller before 1733. His ſpecimen is in Sir Joſeph Banks's herbarium.]

80. This riſes with a ſtrong woody ſtem twenty feet high, dividing into many crooked irregular branches, covered with a light-brown bark. Leaves near four inches long and two broad, which are covered with a ſoft down on their under ſide. Three, four or five ſpikes ariſe from the ſame point, the middle one near three inches long, and the others about half that length. The flowers are ſmall and white. It was found by Dr. Houſtoun at Campeachy; [and was cultivated by Mr. Miller before 1733.

To the above copious liſt of Juſticias we might add many more, that have been diſcovered in the Eaſt and Weſt Indies, at the Cape of Good Hope, Sierra Leone, &c. but theſe are not yet ſufficiently known or determined to lay them before the public.

PROPAGATION AND CULTURE.

Theſe plants are all the produce of warm climates, and not one is a native of Europe. Moſt of them, except a few from the Cape, require the protection of the bark-ſtove. They may be propagated from ſeeds, where theſe can be obtained; and the greater part being ſhrubby, may alſo be increaſed from cuttings. Many of them are beautiful, and would be a great ornament to the ſtove; but few only are yet introduced among us.

The Malabar Nut (n. 57.) and the Snap-tree (n. 64.) were known among us at the end of the laſt century; two or three others were ſent to Mr. Miller by Dr. Houſtoun early in this century; but very few have been introduced ſince.]

57. The Malabar Nut, Juſticia Adhatoda, may be propagated by cuttings, which, if planted in pots in June or July, and plunged into a very moderate hot-bed, will take root; but they muſt be every day ſcreened from the ſun, and if the external air is excluded from them, they will ſucceed better than when it is admitted to them. It may alſo be propagated by laying down the young branches, which will take root in the tubs or pots in one year; then the young plants ſhould be put each into a ſeparate pot, filled with ſoft loamy earth, and placed in the ſhade till they have taken new root, when they may be placed in a ſheltered ſituation during the ſummer, but in winter they muſt be houſed, and treated in the ſame way as Orange-trees, with only this difference, that theſe require more water.

64. The Snap-tree, Juſticia hyſſopifolia, is propagated by cuttings during any of the ſummer months; they ſhould be planted in pots filled with light loamy earth, and plunged into a moderate hot-bed, and ſhaded from the ſun, and now and then gently refreſhed with water, and not too much air admitted to them. In about two months the cuttings will have taken root, then they muſt be gradually inured to the open air, by placing them in a ſheltered ſituation, where they may remain till autumn: if they get root early in the ſummer, ſeparate them each into a ſmall pot, ſetting them in the ſhade till they have taken new root, and place them as above directed; but if it be late in the ſeaſon before they have taken root, let them remain in the ſame pots till the following ſpring. In winter theſe plants muſt be placed in a warm green-houſe or moderately warm ſtove, for they are impatient of cold and damp, nor will they thrive in too much warmth. They will often require water in winter, but it muſt then

[a] Linn. ſuppl. [b] Vahl. [c] Forſkahl. [d] Forſter. [e] Hort. kew. [f] Linn. ſuppl. [g] Linn. ſpec. [h] Jacquin. [i] M.S. Banks. [k] Burman. [l] Vahl. [m] Vahl. [n] Forſter. [o] Swartz. prodr.

be given them moderately. In ſummer they muſt be removed into the open air, in a warm ſheltered ſituation; and in warm weather they muſt have plenty of water.

12. 13. 16. 72. 79. 80. All theſe may be propagated by ſeeds, ſown early in the ſpring, in ſmall pots filled with freſh light earth, and plunged into a moderate hot-bed of tanner's bark, obſerving to water the earth gently as it appears dry. The ſeeds frequently lying a year in the ground, the pots muſt not be diſturbed, if they ſhould not appear; but in the winter ſhould be kept in the ſtove, and the ſpring following plunged into a freſh hot-bed. When the plants begin to appear, the glaſſes of the hot-bed ſhould be raiſed every day, when the weather is warm, to admit freſh air: they muſt alſo be frequently watered in warm weather, but not largely whilſt the plants are young, for they are then ſubject to rot at bottom with much moiſture.

When the plants are about two inches high, take them up carefully, and tranſplant each into a ſmall pot filled with freſh light earth, plunging them into the hot-bed again, watering and ſhading them till they have taken new root: then they ſhould have air admitted to them every day in proportion to the warmth of the ſeaſon, and ſhould be duly watered every two or three days in hot weather.

As the plants advance in their growth, they ſhould be ſhifted into larger pots; for if their roots are too much confined, the plants will not make any conſiderable progreſs; but they ſhould not be over potted, for that will be of worſe conſequence than the other; becauſe when they are planted in very large pots, they will ſtarve and decay, without producing any flowers. They are too tender to endure the open air in this country, therefore they ſhould always remain in the hot-bed, being careful to let them have a due proportion of air in hot weather; and the annual or twelfth ſort ſhould be brought forward as faſt as poſſible in the ſpring, that the plants may flower early, otherwiſe they will not produce good ſeeds in England.

The thirteenth and ſeventy-ninth ſorts ſhould remain in the hot-bed during the ſummer ſeaſon, provided there is room under the glaſſes, without being ſcorched; but at Michaelmas they ſhould be removed into the ſtove, and plunged into the bark-bed, where they muſt remain during the winter ſeaſon, obſerving to keep them warm, as alſo to water them gently once or twice a week, according as they ſhall require. The following ſummer theſe plants will flower, and abide ſeveral years, but they rarely produce good ſeeds in Europe.

The ſixteenth ſort may be more hardily treated, when the plants have obtained ſtrength. This may be alſo increaſed by cuttings, as directed for the Snap-tree (n. 64.); and when the plants are two or three years old, they will thrive in a moderate degree of warmth in winter, and in ſummer they may be placed abroad for two months in the warmeſt ſeaſon; but they ſhould have a ſheltered ſituation, and when the nights begin to grow cold, they muſt be removed into the ſtove, but they muſt have free air admitted to them at all times when the weather is warm. The ſeventy-ſecond and eightieth ſorts ſhould conſtantly remain in the bark-ſtove, and require the ſame treatment as other tender plants from the warmeſt countries.

I. Bulbocodium. *Thunb. diſſ. n.* 3. *prodr. cap.* 9.
Scapes one-flowered, leaves linear, nerved, incraſſated at the edge, ſtigmas ſix.

5. Ixia parviflora. *Small-flowered Ixia.*
Saliſb. prodr. hort. 34. *n.* 3.
Leaves linear, compreſſed, ſegments of the corolla lanceolate, retuſe, the inner ſcarcely wider, ſtigmas biſid, ſpreading-revolute.

6. Ixia fugax, *Fugacious Ixia.*
Saliſb. prodr. hort. 34. *n.* 4.
Leaves linear compreſſed, ſegments of the corolla linear-lanceolate, blunt, the inner wider and more erect, ſtigmas biſid, horizontal-recurved.

7. Ixia humilis. *Humble Ixia.*
Lin. ſyſt. 84. *Thunb. diſſ. n.* 4. *prodr. cap.* 9.
Scape branched, flowers pointing one way, leaves grooved, erect, longer.

8. Ixia piloſa. *Hairy Ixia.*
Lin. ſyſt. 84. *ſuppl.* 92. *Thunb. diſſ. n.* 5. *prodr. cap.* 9.
Leaves linear, hairy, ſhorter, flowers alternate.

9. Ixia hirta. *Rough-haired Ixia.*
Lin. ſyſt. 84. *Thunb. diſſ. n.* 6. *prodr. cap.* 9.
Leaves enſiform, rough-haired, ſhorter, flowers pointing one way.

10. Ixia ſecunda. *One-ranked Ixia.*
Lin. ſyſt. 84. *Thunb. diſſ. n.* 7. *prodr. cap.* 9. *Berg. cap.* 6. *Roche pl. nov.* 17.
Leaves elliptic, enſiform, ſhorter, ſcape villoſe, rugged.

11. Ixia criſpa. *Wave-leaved Ixia.*
Lin. ſyſt. 84. *ſuppl.* 91. *Thunb. diſſ. n.* 8. *prodr. cap.* 9.
I. undulata. *Saliſb. prodr. hort.* 37. *n.* 20.
Leaves linear, waved, ſhorter, flowers alternate.

12. Ixia cinnamomea. *Cinnamon-coloured Ixia.*
Lin. ſyſt. 84. *ſuppl.* 92. *Thunb. diſſ. n.* 9. *prodr. cap.* 9.
Leaves lanceolate waved, ſhorter, flowers alternate.

13. Ixia corymboſa. *Corymbed Ixia.*
Lin. ſyſt. 84. *Thunb. diſſ. n.* 10. *prodr. cap.* 9.
Leaves lanceolate waved, ſhorter, ſcape ancipital.

14. Ixia linearis. *Linear-leaved Ixia.*
Lin. ſyſt. 84. *ſuppl.* 92. *Thunb. diſſ. n.* 11. *prodr. cap.* 9.
Leaves linear, ſhorter, ſcape ſimple, upright.

15. Ixia capillaris. *Slender-ſcaped Ixia.*
Lin. ſyſt. 84. *ſuppl.* 92. *Thunb. diſſ. n.* 12. *prodr. cap.* 9.
I. gracilis. *Saliſb. prodr. hort.* 37. *n.* 22.
Leaves linear, ſhorter, ſcape branched, ſpathe ſcariose.

16. Ixia ſetacea. *Briſtle-leaved Ixia.*
Lin. ſyſt. 84. *Thunb. diſſ. n.* 13. *prodr. cap.* 9.
Leaves linear, ſhorter, ſcape flexuoſe, ſmooth.
17. Ixia ſcillaris. *Squil-flowered Ixia.*
Lin. ſyſt 85. *Reich.* 1. 99. *Thunb. diſſ. n.* 14. *prodr. cap.* 9. *Houtt. hiſt. nat.* 12. *t.* 77. *f.* 2.
Leaves linear, ſhorter, flowers pointing one way, rachis flexuoſe.
18. Ixia aulica. *Cluſter-flowered Ixia.*
Ait. hort. kew. 1. 57.
Flowers in racemes, braĉtes entire, leaves enſiform, flat, nerved, even.]
19. Ixia bulbifera. *Bulb-bearing Ixia.*
Lin. ſpec. 51. *ſyſt.* 85. *Reich.* 1. 99. *amoen.* 4. 300. *Thunb. diſſ. n.* 17. *prodr. cap.* 10. *Mill. fig.* 158. *t.* 236. *f.* 2.
Siſyrinchium æthiopicum majus, &c. *Comm. hort.* 1. 42.
Leaves enſiform, ſhorter, ſpathes membranaceous, briſtle-ſhaped-jagged.
[20. Ixia ariſtata. *Bearded Ixia.*
Lin. ſyſt. 85. *Thunb. diſſ. n.* 15. *prodr. cap.* 9.
α. Corollis purpureis. *Purple-flowered bearded Ixia.*

Bermudiana. *Amm. in Comm. petrop.* 11. 308. *t.* 7.
Leaves enſiform, panicle dichotomous, flowers peduncled.
[39. Ixia fallax.
Saliſb. prodr. hort. 34. *n.* 6.
Border of the corolla incurved and ſpreading very much, ſegments oval, ſlightly emarginate, equal in breadth, filaments ſpreading and recurved, ſtigmas at the baſe of the filaments.

40. Ixia mutabilis.
Saliſb. prodr. hort. 34. *n.* 7.
Border of the corolla deflex, ſalver ſhaped at the baſe, ſegments broadly obovate, retuſe, the inner narrower; filaments from upright ſpreading, ſtigmas below the apex of the tube.

41. Ixia ſocialis.
Saliſb. prodr. hort. 35. *n.* 8.
Border of the corolla horizontal, ſegments elliptical, the outer emarginate, the inner narrower, blunt, filaments from upright ſpreading, ſtigmas at the middle of the filaments.

42. Ixia lineata.
Saliſb. prodr. hort. 35. *n.* 9.
Border of the corolla incurved and ſpreading very much, ſegments oval, blunt, inner narrower, filaments recurved at the tip, ſtigmas below the tip of the filaments.

43. Ixia amoena.
Saliſb. prodr. hort. 35. *n.* 10.
I. maculata. *Schneev. ic.* 25.
Border of the corolla incurved and horizontal, ſegments oval-lanceolate, ſomewhat retuſe, inner narrower; filaments from upright ſpreading; ſtigmas at the baſe of the filaments.

44. Ixia retuſa.
Saliſb. prodr. hort. 35. *n.* 11.
Border of the corolla incurved and ſpreading very much, ſegments oval, retuſe, inner narrower, filaments upright, ſtigmas at the middle of the filaments.

45. Ixia ſpectabilis.
Saliſb. prodr. hort. 35. *n.* 12.
I. maculata viridis. *Schneev. ic.* 6.
Border of the corolla incurved and horizontal, ſegments lanceolate, outer emarginate, inner narrower, blunt, filaments from upright ſpreading, ſtigmas at the baſe of the filaments.

46. Ixia concolor.
Saliſb. prodr. hort. 36. *n.* 14.
Border of the corolla incurved and horizontal, ſegments elliptical, blunt, inner narrower, filaments from upright ſpreading, ſtigmas above the middle of the anthers.

47. Ixia conica.
Saliſb. prodr. hort. 36. *n.* 15.
Border of the corolla reflex, ſhaped like a diſh at the baſe, ſegments elliptical, blunt, inner broader; filaments upright, ſtigmas above the baſe of the anthers.

48. Ixia conſpicua.
Saliſb. prodr. hort. 36. *n.* 16.
Border of the corolla incurved and horizontal, ſegments elliptical blunt, inner narrower; filaments from upright recurved, ſtigmas at the baſe of the filaments.

49. Ixia concinna.
Saliſb. prodr. hort. 36. *n.* 17.
Border of the corolla reclining, funnel-form at the baſe, ſegments elliptical, blunt, inner narrower, filaments from upright recurved, ſtigmas below the middle of the filaments.

50. Ixia columnaris.
Saliſb. prodr. hort. 36. *n.* 18.
Border of the corolla the length of the tube, reflex, ſalver-ſhaped at the baſe, ſegments elliptical, the inner a little wider; filaments monadelphous; ſtigmas above the baſe of the anthers.

51. Ixia eroſa.
Saliſb. prodr. hort. 36. *n.* 19.
Margins of the nerves duplicate-ciliate, baſe of the corolla funnel-form, ſegments elliptical, gnawn at the tip.

52. Ixia tardiflora.
Saliſb. prodr. hort. 38. *n.* 29.
Border of the corolla recurved at top, ſegments broadly ſpatulate emarginate, the three lower at the diſk of the baſe within, putting out a little keel, ſtigmas at the baſe of the anthers.

53. Ixia propinqua.
Saliſb. prodr. hort. 38. *n.* 30.
Border of the corolla recurved and ſpreading at top, ſegments ſpatulate, ſlightly emarginate, the three lower approximating a little, at the diſk of the baſe within putting out a little keel; ſtigmas at the middle of the anthers.

54. Ixia ambigua.
Saliſb. prodr. hort. 39. *n.* 32.
Border of the corolla recurved a little at top, ſegments rhomb-ſpatulate, equal in breadth, the outer ſomewhat gibbous at bottom, emarginate, inner blunt, ſtigmas above the middle of the anthers.

DESCRIPTIONS, *&c.*

Root fibrous or tuberous tunicated. Leaves flat ſheathing at the edge or channelled, or nerved and graſs-like. Stem often compreſſed, ſometimes ſcarcely any. Flowers terminating, ſolitary, or in ſpikes, panicles or heads. Spathes ſubuniflorous. The ſubſeſſile lobe of the germinating ſeed is faſtened to the back of the primary ſheath of the leaves [a].

Ixia differs from Antholyza in having the ſegments of the corolla nearly equal; from Gladiolus in the ſituation of the ſegments of the corolla, and in having the tube ſtraight. A few of the ſpecies are referred by ſome to Moræa; whilſt others would ſink that genus in this.

The Spathe is longer or ſhorter than the tube in different ſpecies, blunt or ſharp, entire or lacerated, ſmooth or hirſute. The tube of the corolla is more or leſs deeply parted; ringent, cylindrical or filiform; ſimple, that is, nearly equal; or double, that is, filiform at the baſe, and then cylindrical; curved or jointed. Border moſt commonly bell-ſhaped; equal or unequal; reflex, ſpreading, and curled or waved, but ſeldom [b].

Almoſt all the ſpecies are natives of the Cape of Good Hope.

1. Stem ſuffruticoſe, branched, the whole ſmooth and covered with leaves, a hand or ſomewhat more in height. Leaves linear, attennuated at the tip, ſubfalcated, very finely ſtriated, very cloſely imbricated, from an inch to two inches in length. Flowers terminating, blue. Spathes membranaceous. Tube of the corolla yellow, half an inch in length. Native of the Cape, and of Terra del Fuego.

2. Bulb globular, covered with a net, the ſize of a pea. Leaves included in a ſheath, linear, concave above, convex beneath, ſmooth, upright, the length of the ſcapes, and one to each ſcape. Scape ſeldom ſingle, commonly two to four or more, ſimple, round, upright, ſmooth, pale purple, an inch long. Bractes two, a little above the middle, linear-filiform, oppoſite, upright, ſcarcely a line in length. Calyx none, except the bractes. Tube of the corolla white, with purple ſtreaks. Segments of the border concave above of a ſnowy whiteneſs, underneath white, with a double purple ſtreak, the length of the tube, half a line in length. Anthers upright, yellow. Capſule green, with purple ſtreaks. The whole appearance is ſo like that of *Fabricia minuta*, that unleſs the ſtamens, ſtigma and bulb be inſpected, it ſeems to be the ſame [c].

3. Bulb roundiſh, placed on the withered bulb, double the ſize of a pea, white, covered with a bay-coloured ſkin. Leaves three or four, in the flowering plant radical, in the fruiting cauline, ſpreading horizontally, half a foot or thereabouts in length, ſmooth, ſharpiſh. Stem ſolitary, upright, two inches high, above the uppermoſt leaf convex on one ſide, flat on the other; in the fruiting plant a little higher, in the cultivated one ſometimes half a foot high. Spathe terminanting, two-valved; leaflets narrow-lanceolate, acute, concave, oppoſite; one upright, green, almoſt the length of the corolla; the other a little ſhorter, green on the back, but otherwiſe membranaceous and pellucid, patulous, whence the flower becomes as it were lateral. It is inodorous. The corolla pale violet, yellow on both ſides at the baſe: the outer ſegments are commonly more yellow on the outſide, with browniſh ſtreaks. Stamens yellow. Germ green. Style and ſtigma pale yellow. Capſule ſmooth and aſh-coloured, larger than a pea. Seeds ſhining, browniſh [d].

Native of Italy. Cultivated 1739 in the botanic garden at Cheſea [e]. It is not the Bulbocodium of Miller. It flowers about the middle of april; but the

[a] Juſſieu. [b] Thunb. & Schreb. gen. [c] Thunb. diſſ. [d] Jacquin. [e] Hort. kew.

bloſſoms

bloſſoms do not fully expand unleſs expoſed to the ſun, nor are they of long duration. It affects dry hilly ſituations[f]. It is ſaid to have been found in Guernſey and Jerſey.

4. Bulb ovate, ſmooth, ſubtruncated. Scape three (or four) cornered, ſheathed at bottom, branched, few-flowered, ſmooth, from a hand to a ſpan in height. Leaves acute, grooved, ſmooth, the loweſt, which is the longeſt, frequently double the length of the ſcape, or more, is lax and reflex; the two or three others are about the length of the ſcape, and upright. Flowers at the ends of the branches, rather large, coming out one after the other. Outer ſpathe ovate, green; inner lanceolate, acute, membranaceous, ſheathing the capſule. Tube of the corolla very ſhort: ſegments of the border yellow within, with three brown ſtreaks, greeniſh-yellow on the outſide. Filaments pubeſcent. Stigmas ſix, reflex.

It varies with the three inner ſegments of the corolla yellow, and the three outer green; the three inner white-yellow, the three outer greeniſh; the three inner blue-white, the three outer greeniſh; the three inner white, the three outer green; with corollas wholly yellow, or wholly blue, or roſe-coloured with a yellow baſe. It varies alſo in the ſize of the flowers. The ſcape is really many-flowered, but ſometimes one-flower only opens. The leaves are filiform, linear or enſiform, uſually longer than the ſcape, and frequently reflex[g].

This and the preceding were ſeparated in the thirteenth edition of Syſtema Vegetabilium; but were conſidered as one ſpecies by Murray in the fourteenth: as they are by Thunberg in his Monographia. They ſeem, however, to be very diſtinct; the leaves of this being three or four-ſided from the rib raiſed on both ſides, and thickened at the edge. The ſame bulb alſo puts up ſeveral ſcapes. It is a native of the Cape, and was cultivated in 1758 by Mr. Miller[h].

5. The leaves of this are very narrow, being only half a line in width. The tube of the corolla is only a line long. It was gathered wild in Jerſey, by Mr. R. Finlay[i]. Mr. Lambert aſſures me that it is in Hudſon's herbarium, among his Jerſey plants, now in Mr. Lambert's poſſeſſion. Probably only a variety of the third.

6. Leaves only one line in width. Tube of the corolla only a quarter of a line long. Found at the Cape by Maſſon.

This and the preceding are very nearly allied to I. Bulbocodium.

7. Bulb ſmooth, the ſize of a hazel nut. Scape ſimple or branched, filiform, upright, from a hand to a ſpan in height. Leaves two or three, linear, many-grooved, ſmooth, longer than the ſcape. Flowers in racemes, three to eight on a flexuoſe rachis. Spathes green, truncated. It varies with the corolla yellow, whitiſh ruſeſcent, or fleſh-coloured; with an undivided few-flowered ſcape, and a branched many-flowered ſcape.

8. Bulb globular, ſmooth, ſcarcely as big as a pea. Leaves acuminate, about three, upright, ſtriated; only about half the length of the ſcape. Scape ſimple, round, upright, ſmooth, many-flowered, a hand or more in height, duſky purple at top. Flowers ſeſſile, ſomewhat nodding. Corolla ruſeſcent without, white within. Segments of the corolla concave, the three lower white, the three outer white within, greeniſh-purple on the outſide, with a white edge. Anthers linear, bifid at the baſe, inſerted at the back above the baſe, yellow. Stigmas from upright bent in, rough-haired, white. Capſule ſix-grooved. The flowers open from four in the afternoon.

9. Leaves ſtriated, villoſe, ſhorter than the ſcape. Scape ſimple, inflex-erect, ſmooth. Flowers dark blue. Spathes entire. It reſembles the next ſpecies very much, but the leaves are very villoſe, with white hairs.

10. Bulb imbricate downwards, hard, the ſize of a pea. Leaves attenuated next the baſe, ſmooth, nerved with the midrib thicker, upright, only half the length of the ſcape. Scape round, flexuoſe, upright, ſeldom ſimple, moſt frequently branched, the branches flexuoſe and ſpreading, from a ſpan to a foot in height. Flowers generally four, five or ſix, ſeldom fewer, upright, blue, pointing one way, on a flexuoſe rachis. Spathes green at the baſe, brown at the tip, entire. This ſingular plant is diſtinguiſhed from the reſt by its flexuoſe rachis and its villoſe-rugged ſcape. It varies with the ſcape ſimple and branched.

11. Bulb netted, ovate. Leaves about five, linear-lanceolate, acute, moſt elegantly curled (or waved) on the edge, ſmooth, with a thick longitudinal nerve, not half the length of the ſcape. Scape ſimple or branched, round, ſmooth, flexuoſe upright, many-flowered, about a foot in height. Flowers remote. Outer ſpathe three-toothed, ſtriated, with as many nerves; inner two-toothed, with two nerves. Tube of the corolla greeniſh; ſegments of the border blue. Anthers fixed at one end, inflex. Stigmas from reflex ſpreading, club-ſhaped at the end. It varies with the ſcape ſimple and branched; with the corollas blue and white.

12. Bulb conical, imbricate downwards, truncated, with a ſharp fibrous edge, ſmooth, the ſize of a pea. Scape ſimple, round, from flexuoſe upright, green-purple, ſmooth, a ſpan high. Root-leaves two, ſheathing, blunt, ſubfalcate-reflex, with the midrib raiſed, and the edge curled or waved, a finger's length, one third of the length of the ſcape: of the cotyledon one, embracing, ovate, obtuſe, reflex at the tip, entire, ſmooth: ſtem-leaves two, ſpathe-form, remote; the lower convolute-ſheathing with a long ſheath, compreſſed at the tip, obverſe: often curled, ſmooth, from an inch to three inches in length. Flowers pointing one way, upright, from three to nine. Rachis ſubflexuoſe, ſmooth. Outer ſpathe concave, blunt with a point, ſmooth, green with a purple tip, a little ſhorter than the tube, a line in length: inner nearly equal, bifid. Tube of the corolla a little enlarged, and ſomewhat curved, purpliſh: the three inner ſegments of the border entirely white; the three outer white within, purple-ſtriated without. Anthers upright, inſerted into the back above the baſe, linear-awl-ſhaped, ſhorter than the border, yellow. Capſule ſix-ſtreaked.—The ſpike of flowers reſembles that of *Gladiolus recurvus*, but the corolla is regular. In its curled leaves it reſembles the preceding, but the leaves are lanceolate, two lines wide.

23. Bulb ovate, truncated, netted. Root-leaf ſingle, enſiform, ſtriated, recurved, ſmooth, a finger's length, only half the length of the ſcape. Stem-leaves one or two, ſpathe-form, embracing, ſtriated, decurrent, ſmaller. Scape ſimple at bottom, panicled at top, ſtriated, ſmooth, flexuoſe, upright, a ſpan high. Branches alternate, dichotomous, compreſſed, faſtigiate. Flowers terminating on ſubumbelled faſtigiate branches. Spathe green, with a blunt red tip. Tube of the corolla gradually widening, the length of the ſpathe: ſegments of the border lanceolate. Stigmas globular at the tip. —It varies with white and with blue flowers.

14. Bulb ovate, fibrous, even, the ſize of a hazel nut. Scape round, ſmooth, a hand or a ſpan high or more. Leaves above three: the lower far-ſheathing, linear, convex on both ſides, with a raiſed line in the middle, very narrow, being ſcarcely half a line in width, upright, a little attenuated at the tip, entire, ſmooth, a little ſhorter than the ſcape, ſeldom equal to it: the two upper ſpathaceous, very ſhort. Flowers commonly two or three (ſeldom one) pointing the ſame way. Spathe convolute, lanceolate, acute, ſtriated, ſmooth; the outer larger, the length of the corolla. Tube of the corolla whitiſh: ſegments of the border blunt, with a point. Stigmas revolute-ſpreading, purpliſh. Capſule ſcarcely angular, ſix-ſtreaked.

15. Bulb netted, fibrous, the ſize of a hazel nut. Leaves nerved, ſmooth, ſhorter by half than the ſcape. Scape round, divided at the tip, capillary, upright, two feet high, with pedicel-ſhaped one-flowered branches. Flowers terminating the branches, or at the end of the ſcape, alternate, ſeſſile, upright, whitiſh, netted-veined. Spathes ſcarioſe, with duſky veins,

[f] Curtis. [g] Thunberg. [h] Hort. kew. [i] Saliſbury.

toothed. The flowers in this ſpecies ſeem peduncled, but the branches are one-flowered [s].

The tube of the corolla is ſhorter than the bractes, broad-funnel-ſhaped; the border is contracted at the baſe, and the ſegments are linear [t].

16. Leaves acute, very narrow, ſhorter than the ſcape, with a raiſed line in the middle, ſmooth, about three; in the middle of the ſcape is a ſhort leaf reſembling the ſpathes. Scape filiform, upright, few-flowered, red, a finger's length, ſimple, branched or bifid. Spathe ſubinflated, green, very concave, ſtriated, ſmooth, the length of the tube. The three outer ſegments of the border of the corolla are white within, red-ſtreaked without; the three inner entirely white. Style longer than the ſtamens, ſhorter than the corolla, filiform, white.—It varies with a greeniſh corolla, white at the tips, and with a yellow corolla, with the baſe of the border duſky—with the ſcape one-flowered, many-flowered and ſimple, many-flowered and branched.—That with a duſky baſe reſembles I. maculata; but it is ſeveral times ſmaller, branched, and the leaves linear and narrow.

17. Scape round, upright, ſmooth, ſheathed, branched, a foot high. Branches filiform, naked, flexuoſe, lax, ſmooth, flowering. Leaves far-ſheathing, about three, thickiſh, ſcarcely half a line in width, with a deep double ſtreak, a ſpan long. Flowers remote, frequently about ten. Outer ſpathe a little larger, ſmooth, ſtriated, green at the baſe, aſh-coloured at the tip, membranaceous, entire: inner green at the baſe; membranaceous, bifid and aſh-coloured at the tip. Tube of the corolla very ſhort, greeniſh-yellow: ſegments of the border concave, yellow; the three outer purpliſh on the back. Stigmas involute, villoſe, yelloviſh. Capſule obſcurely three-cornered, ſix-grooved. Seeds ſomewhat kidney-ſhaped [u].

Thunberg ſuſpects, that the *flexuoſa* of Linneus's ſpecies (n. 24.) and the *ſcillaris* of the ſpecies and ſyſtema, may be the ſame with the *ſecunda* (n. 10.) of himſelf and Bergius. *I. ſcillaris* of Miller is *Gladiolus plicatus*.

18. Introduced from the Cape by Mr. Maſſon in 1774. It flowers in april [x].

19. Scape ſimple or branched, ſomewhat compreſſed, ſtriated, ſmooth, ſheathed at bottom with leaves, from a hand to a foot in height. Leaves nerved and ſtriated, diſtich, upright, ſmooth, a ſpan long. Flowers three or more, large, with the rachis between the flowers flexuoſe. Spathe nerved and netted, gray with a duſky tip. Tube of the corolla only a line in length: border divided beyond the middle, but not to the tube: ſegments large, ovate-oblong, very blunt, ſpreading. Anthers linear, long, convex within, lamelloſe and white without. Capſule ſix-ſtreaked. It varies with the corolla purple, red and white, yellow; with the ſcape very ſhort and ſimple, higher and branched, and bulbiferous [y].

It was cultivated in 1758, by Mr. Miller, as appears from his figures.] According to him, the bulb has a netted coat; the ſtalk riſes near a foot and half high; leaves at each joint, flat, ſmooth, embracing, of a lucid green, and differing greatly in ſize; the flowers are produced towards the top of the ſtalk, each having a ſhort withering ſpathe; ſegments of the corolla lanceolate, equal, ſpreading, acute, white within with a pale purple ſtripe down the middle; on the outſide they have broad deep-purple ſtripes; their baſe is marked with a yellow ſpot. The ſtalks have bulbs formed at each joint at the baſe of the leaves. It flowers in may and june.—In the Dictionary he ſays, that the corolla is of a ſulphur colour. His ſpecimen is in the Bankſian herbarium, with the corolla purple on the outſide.

[20. Bulb netted, the ſize of a hazel nut. Scape ſimple, round, upright, ſmooth, from a hand to a foot in height and more. Leaves four or five, linear, five-nerved, the middle nerve and edges thicker, acute, upright, ſhorter by half than the ſcape. Flowers pointing one way (very ſeldom one only) on two branches, often form five to nine on a ſcarcely flexuoſe rachis. Spathes ſubmembranaceous, awn-toothed. Corollas white-fleſh coloured [z].

α. Root-leaves ſeveral, diſtich, narrow, enſiform, erect, acute, very finely ſtriated, ſmooth, very unequal in length, the longeſt half a foot. Scape higher than the leaves, round, ſmooth, flexuoſe, almoſt upright. Flower terminating, erect, inodorous. Spathe ſcarioſe, ſmooth, two-valved; valves ſtriated, broad, awn-toothed. Tube of the corolla narrow, incurved a little, dark violet colour, the length of the ſpathe: border ſpreading, an inch and half in diameter; ſegments oblong, blunt with a little point, equal, of a very deep and elegant purple-violet colour within, three of them of the ſame colour on the outſide, but the three others alternately of a pale dirty violet; one of theſe with two on the ſide of it has a double band in the throat meeting at one end. Anthers pale yellow. Stigma triſid, filiform, white. It flowers in april [a].

β. It varies, as Mr. Saliſbury obſerves, with whitiſh corollas having a purple ſtar, violet-coloured and yellow. Mr. Miller has repreſented ſome of theſe in his 237th plate. Fig. 1. he ſays, has the corolla of a beautiful purple on the outſide, but white within. The ſtem is terminated by two or three flowers. In fig. 2. the ſtalk is terminated by two large flowers; the outſide of a violet-colour edged with white, the inſide pale blue. The term *uniflora* is improperly applied to theſe; and therefore Mr. Saliſbury has adopted that of *grandiflora*. Fig. 3. is one-flowered, and the corolla is of a moſt beautiful purple colour both within and without [b].—Theſe were cultivated by Mr. Miller in 1758 [c].

21. Mr. Saliſbury gives this as very diſtinct from the preceding, but we have no farther deſcription of it than is given in the ſpecific character.

22. Bulb rounded-ovate, the ſize of a hazel nut, brown and ſtriated on the outſide. Leaves ſeveral, enſiform, upright, far-ſheathing at the baſe, villoſe on both ſides and at the edges, with a ſmooth ſtriated ſheath. Scape villoſe the length of the leaves, few-flowered. Spathes three-valved, green, concave, acute; the outer valve much longer. Flowers alternate, ſeſſile, upright, often three. Tube of the corolla pale purple: border very deep purple; ſegments nearly equal, lanceolate, acute, one-coloured, ſpreading very much, the ſame length with the tube. Filaments purple, half the length of the border of the corolla. Anthers oblong, black-violet. Germ hirſute green. Stigma triſid, of the ſame colour with the corolla, with the ſegments widening at the tip [d].

This is not the *villoſa* of Jacquin (collect. 167. ic. vol. 2. t. 284.) though he ſays it differs from the *villoſa* of the Kew Catalogue, only in the colour of the flower.

Mr. Saliſbury refers both the *villoſa* of the Kew Catalogue and the *purpurea* of Jacquin to his *I. ſtabelliformis*, and we have followed him in conſidering them as one plant. He obſerves that it differs from the *Gladioli* only in the regularity of the corolla.

This ſpecies was introduced into the royal garden at Kew from the Cape in 1788, by Patrick Ruſſel, M.D. [e]

23. Root jointed like a necklace: joints ſeveral in a ring, depreſſed, approximating, fleſhy, ruſeſcent. Root-leaves ſheathing the bottom of the ſcape, acute, ſtriated, ſmooth, a foot long or a little more. Scape round, ſmooth, upright, the thickneſs of a writing pen at bottom, divided at top into a capillary, nodding, flexuoſe branches, a fathom in height. Spathes membranaceous, jagged. Corollas on the branches alternate, large, fleſh-coloured, with a ſhort tube. This is the loftieſt of all the Ixias, and the large pendulous corollas are very handſome [f].]

24. Bulb very ſmall, round. Leaves three or four, long, ſlender, graſs-like, dark green. Stem very ſlender, round, a foot and half high; at the top the flowers are collected in a ſpike ſitting cloſe to the ſtalk, each having a thin, dry ſpathe, which covers the capſule after the flower is fallen. The corolla is pure

[s] Thunberg. [t] Saliſbury. [u] Thunberg. [x] Hort. kew. [y] Thunberg.

[z] Thunberg. [a] Jacquin. [b] Mill. fig. [c] Hort. kew. [d] Jacquin. [e] Hort. kew. [f] Thunberg.

white, and ſmall. Capſule ſmall, round. It flowers at the end of may, and the ſeeds ripen in july.

[That which is figured by Mr. Curtis is a variety with a purple eye. He ſays that the flowers are fragrant, and come forth in april or may.—It was cultivated in 1757 by Mr. Miller [a]. His ſpecimen is in the Bankſian herbarium.

Thunberg doubts whether the *Ixia flexuoſa* of Linnæus's ſpecies may not be the ſame with his *ſecunda*.

25. Bulb the ſize of a hazel nut. Leaves three or four, many-nerved, upright, ſmooth, half the length of the ſcape. Scape round, ſmooth, upright, many-ſpiked, from a foot to two feet in height. Branches alternate, capillary, upright, a finger's length. Flowers on the ſcape and branches in ſpikes, on a flexuoſe rachis of a finger's length. Spathes ſubmembranaceous and awned. It varies with the corollas yellow and violet, of one colour [b].]

Leaves four or five, ſix or ſeven inches long. Stalk ſlender, ten inches high, from the ſide of which come out one or two cluſters of flowers on ſhort peduncles, and at the top of the ſtalk the flowers grow in a looſe ſpike; they are of a pure white, and appear in may: the ſeeds ripen in july.—[Cultivated in 1757, by Mr. Miller [c].

26. Scape four or five ſpans in height, the thickneſs of Rie ſtraw, upright, round, even, yelloviſh, naked at top and branched. Branches ſimple, alternate, naked, flowering, diſtant. Leaves about ſix, acute, three ſpans long, ſtriated and nerved, ſmooth, yelloviſh green, upright, radical; inner ſheathing. Flowers in ſpikes, yellow. Spikes filiform, ſeveral on a ſcape, with the flowers alternate, diſtant, nodding; rachis ſomewhat flexuoſe. Spathes bivalve: valves oblong, acute, membranaceous, whitiſh, ſtriated, concave, embracing each other, involving the germs, of which they are double the length; one is keeled, the other two-angled, with a bifid tip [d]. Tube of the corolla two, three or four inches in length, funnel-form; border recurved at top, ſegments linear, the outer retuſe, the inner narrower [e].

This ſpecies is eaſily diſtinguiſhed by the extraordinary length of the tube of the corolla. Thunberg ranges it under *Gladiolus*, becauſe this tube is a little curved; though he confeſſes that it has the appearance of an *Ixia*.

It was introduced in 1774, by Mr. Maſſon, and flowers here from april to june [f].

27. Root conſiſting of ſeveral little bulbs. Scape ſheathed with leaves, round, from flexuoſe upright, many-ſpiked at top; ſpikes alternate, wand-like; a ſpan high. Leaves two or three, alternately ſheathing, ſtriated, ſmooth, ſhorter than the ſcape, the upper ones gradually ſhorter. Flowers very ſmall. Spikes linear, a finger's length, upright. Spathes with a membranaceous, white margin. Tube of the corolla ſcarcely longer than the ſpathes. It varies with the ſcape ſimple and branched; with the coroллas white and blue [g].

Introduced in 1774, by Mr. Maſſon. It flowers in june and july [h].

28. Scape ſimple and many-ſpiked, ſomewhat woody, ſheathed with leaves round, ſmooth, ſtiff and ſtraight, almoſt the thickneſs of a finger, from a foot to four feet in height. Leaves ſheathing, ſhorter than the ſcape, half an inch wide, with a thick yelloviſh vein along the middle and at the edge, marked in lines with ſmaller raiſed yelloviſh veins, ſmooth, upright; the lower longer, a foot and more long; the upper only a ſpan in length, preſſed cloſe. Flowers large, pendulous. Spike with alternate flowers, from a finger to a foot in length, with a flexuoſe rachis [i].

29. Bulb flatted. Scape ſimple, round, ſmooth, longer than the leaves, from ſix inches to two feet in height. Leaves ſtriated, withering at the end. Flowers in a ſort of ſpike, containing from ten to twenty flowers: each peduncle is ſurrounded at the baſe with a ſpathe, the ſegments of which terminate in a ſhort awn. Corolla very deeply ſix-parted, of a bright red colour [k].

Mr. Saliſbury, who in his ſpecific characters of the Ixias, gives the proportion between the tube and the limb or border, ſays that the latter is one and a half longer than the former; that the border is curved inwards and ſpreads very much: that the ſegments are elliptical, retuſe, the inner ones narrower.

It was introduced in 1779, by William Pitcairn, M.D. and flowers in april [l].

30. Bulb double the ſize of a hazel nut. Leaves three, four, or five, many-nerved, half the length of the ſcape. Scape uſually ſimple, ſeldom many-ſpiked, round, upright, from a ſpan to a foot high and more. Branches filiform, upright, or ſpreading very much. Flowers in terminating ſpikes, on a flexuoſe rachis. Spathes membranaceous, gray at the baſe, brown at the tip, ſomewhat jagged. The corolla, above the mouth of the tube, has a duſky ſpot at the baſe of the border. It bears ſo much reſemblance to *I. erecta*, (polyſtachia, n. 25.) as to differ in little elſe, beſides the ſpot in the corolla [m].]

Mr. Miller ſays that the bulb is oval and compreſſed; that the leaves are ſmooth, near a foot long, and a quarter of an inch broad, with two ſharp edges, of a deep green, and ending in acute points. Stalk ſlender, ſtiff, a foot and half long, naked to the top, where it is terminated by a round bunch of flowers, each incloſed in an oblong ſpathe, which is permanent, and ſplits open on one ſide. Flowers on ſhort peduncles, deep yellow with a dark purple bottom.

[It was cultivated in 1757 by Mr. Miller, and flowers in may and june [n].

31. Leaves linear-lanceolate, acute, quite entire, flat, ſmooth, a ſpan long. Scape round, ſmooth, ſimple. Flowers remote. Bractes two at the baſe of each germ, broad, membranaceous, cloven, ſcarcely half an inch long. Corolla fulvous; tube cylindric-bell-ſhaped, narrow; ſegments of the border ovate, blunt, ſlightly emarginate, more than an inch in length attenuated at bottom into broad claws; the three outer gibbous at bottom (whence the border at the baſe is triangular-pitcher-ſhaped), marked in the middle with a dark red ſpot, and within have a raiſed keel, at top ſpreading; the three inner almoſt upright, flat, unſpotted: at the throat there is a greeniſh yellow ſtar-like ſpot.

Introduced in 1774, by Mr. Maſſon. It flowers in may [o].

Mr. Saliſbury changes the name from *deuſta* to *gibba*, chooſing to denominate it from the form rather than the colour of the flower.

32. Bulb a little larger than a hazel nut. Leaves about five, reflex-ſubfalcate, many-nerved, from an inch to a finger's length, half or one-third of the length of the ſcape. Scape ſimple, round or branched, ſomewhat flatted, flexuoſe, upright, ſmooth, from a hand to a ſpan in height. Branches ſpreading very much, naked, like the ſcape. Bractes gray at the baſe, ferruginous at the tip, ſlightly toothed and jagged. Flowers pointing one way, handſome, bell-ſhaped, with a ſhort tube, orange-coloured with a paler hyaline or tranſparent mark above the mouth of the tube; ſeldom two, but moſt commonly five or ſeven.

It varies with a ſhort ſimple few-flowered ſcape, and a dark ſpot above the windowed or hyaline one: with a lofty, many-ſpiked, many-flowered ſcape: and with bright red flowers.

This is one of the handſomeſt of the Ixias, and like other ſorts becomes handſomer and more branched by cultivation [p].

Mr. Saliſbury thinks that the name of *hyalina* agrees better with this ſpecies; and gives the name of *ſimilis* to the *hyalina* of the younger Linnæus's ſupplement; *ſqualida* α, of the Kew Catalogue. See the next ſpecies.]

According to Mr. Miller, the bulb is oval, ſmall a little compreſſed, and has a ſmooth dark-coloured coat; whence come up three or four narrow, thin, flat,

ſmooth

ſmooth leaves of different lengths, ſome four or five inches long, others ſeven or eight to near a foot, near half an inch broad where wideſt, but narrow at both ends and terminating in points. The flower-ſtalk riſes a little above the leaves; it is very ſlender, naked, except at the joint, where it is crooked, and has a ſmall leaf embracing it. Flowers terminating, in a round cluſter; each having a ſhort, withered, cloven ſpathe. Tube ſhort and ſwelling; ſegments of the border broad, blunt, ſpreading, equal, bright orange or deep gold-colour, with a large black ſpot at the baſe.

[It was cultivated in 1758, by Mr. Miller, and flowers in may and june [o].

33. *α.* Very nearly allied to the preceding, but the ſegments of the border in the corolla are narrower and more pellucid, the veins therefore ſtand more out; they are alſo ſlightly emarginate. The colour in this is pale ruſeſcent, or dirty fleſh-colour, with a little tinge of yellow [p].

According to Saliſbury, the border of the corolla is five times as long as the tube in the preceding, but only three and a half in this; it ſpreads at top in this but is curved back in that: in the preceding the whole ſides are hyaline at bottom, whereas the edges are only ſo in this: the ſtigmas reach up to the tip of the anthers in that, but in this they are lower.

β. Leaves acuminate, ſtrict, flat, ſmooth, ſcarcely a ſpan in length. Scape round, ſmooth, twice as long as the leaves. Flowers remote. Bractes two at the baſe of each germ, membranaceous, cloven at the tip, ſcarcely half an inch in length. Corolla pale-yellow, with duſky veins; tube funnel-form; ſegments of the border ovate-oblong, bluntiſh, quite entire; outer near the tip ſometimes red; one of the inner a little wider than the others.

Introduced in 1774, by Mr. Maſſon. It flowers in may [q].

Mr. Saliſbury makes this a ſpecies of Gladiolus, and gives this ſpecific character—limb of the corolla four times as long as the tube, curved inwards ſpreading, ſegments elliptical, with three parallel lines on the outſide; the uppermoſt larger, the outer ones retuſe.

34. Bulb cloſely involved in the rudiments of leaves, larger than a hazel nut. Leaves three or four, lanceolate-enſiform, thicker about the edges and along the midrib, the edges turned back, very finely ſtriated, ſmooth, upright, a finger's length. On the ſcape a ſpathe-form leaf or two. Scape round, compreſſed, upright, ſmooth, twice as long as the leaves. Flowers about ſix, purpliſh white. Spathes aſh-coloured, ferruginous at the tip, blunt, entire.

35. Scape branched or ſimple, round, flexuoſe, ſmooth, a foot high. Leaves ſtriated, ſmooth, ſeveral times ſhorter than the ſcape. Spike of flowers long, interrupted, flexuoſe. Spathe membranaceous, marked with ſix lines, the length of the tube; the outer larger, keeled, three-toothed. Tube of the corolla greeniſh, ſhort; ſegments of the border purple. Filaments generally three, ſometimes five or four, inſerted into the mouth of the tube, half the length of the border, filiform, whitiſh. Anthers ovate, incumbent or nodding horizontally, ſomewhat compreſſed, twin, yellow. Stigmas generally three, ſometimes five or four, reflex-ſpreading, a little ſhorter than the filaments, blunt, a line in length, feathered. Capſule three-cornered, ſix-grooved. When there are four filaments, two often are united into one body with four ſtigmas, the anthers ſeparate or united. It varies with three-ſtamened flowers having three ſtigmas; with four-ſtamened flowers having four ſtigmas; and with five-ſtamened flowers having five ſtigmas.

36. Bulb conical, imbricate downwards, truncated with a ſharp fibroſe margin, the ſize of a pea. Scape ſimple and branched, ſmooth, purple at top, many-flowered. Leaves diſtich, ſtriated, ſmooth, ſhorter by half than the ſcape. Flowers alternate, one, two or more. Tube of the corolla red: the three inner ſegments of the border rounded, white; the outer white within, red without. Stigmas flexuoſe-involute, rough-haired.

[o] Hort. kew. [p] Ibid. [q] Ibid.

It varies with the ſcape ſimple or branched, a hand or a ſpan in height; with flowers alternate or pointing one way; with the trachis very flexuoſe or ſcarcely ſo at all.

37. Bulb globular, ſmooth, leſs than a pea. Root-leaves two, ovate, blunt, ſmooth, embracing by the inner edge, and there cut out as it were for the paſſage of the ſcape, ſpreading, reſembling one bifid leaf: below the middle of the ſcape there is a ſolitary leaf like a ſpathe. Scape round, upright, ſmooth, one-flowered or many-flowered, a finger or a hand in length. Spathe ſmooth, blunt and ſubcrenate at the tip; the outer green, ſhorter than the tube. Tube of the corolla red: ſegments of the border very blunt, ſpreading, on the outſide ruſeſcent ſtreaked with red, on the inſide white ſtreaked with red. Anthers brown, upright. Stigmas ſmall, revolute, rough-haired. Sometimes, but very ſeldom, the ſtem puts out a one-flowered ſtemlet in the middle [r].

38. Scape round, fiſtulous, jointed, upright, ſimple at bottom, panicled-dichotomous or trichotomous at top, ſmooth, almoſt the thickneſs of a finger, two feet high. Leaves alternate, embracing, equitant, acute, entire, ſtriated, ſmooth, the lower a little longer, about half the length of the ſtem, a ſpan long and more. Flowers from the tips of the branches of the panicle in umbels, from three to ſeven, peduncled. Peduncles ſtriated, one-flowered, an inch long. Spathe under the diviſions and the umbel, withered. Corolla connected only by the baſe, yellow and purple ſpotted: claws narrow; border oblong, ſpreading, blunt, entire, three alternate ones a little narrower. Filaments capillary. Anthers linear. Capſule oblong [s].

There is a diſagreement about the genus of this plant. Thunberg places it with the Moræas, and ſays that it cannot be referred to the Ixias, becauſe the flower is not in the leaſt tubular, but ſix-petalled.

Loureiro deſcribes the bulbs as cylindric, branched, with long fibres. Leaves lanceolate-linear. Stem three feet high, two-edged at bottom, round at top. Flowers large, terminating, golden-coloured, dotted with red, in an upright few-flowered panicle. He would unite the two genera of Ixia and Moræa, as ſcarcely differing.

Mr. Saliſbury makes it a *Ferraria*; which genus he ſays differs from Iris only in having no tube to the corolla. This ſpecies, he obſerves, has the ſeeds as in Iris foetidiſſima, with a pulpy arillus.

The accurate Gærtner deſcribes the capſule as inferior, ovate, contracted towards the baſe, rounded-three-cornered, coriaceous. Receptacle awl-ſhaped, three-ſided, free in maturity. Seeds ſeveral, ſix to ten in each cell, ſpherical, ſmooth, black, ſhining, berried, fixed in a double row to the angles of each cell.]

In India, the ſtalks riſe to the height of five or ſix feet, but in England they are ſeldom more than half that height. It has a pretty thick fleſhy root, divided in knots or joints of a yelloviſh colour, ſending out many fibres; the ſtalk is pretty thick, ſmooth, and jointed; leaves a foot long and one inch broad, with ſeveral longitudinal furrows, embracing the ſtalks with their baſe, ending in acute points; the upper part of the ſtalk divaricates into two ſmaller, with a footſtalk ariſing between them, which ſupports one flower, the ſmaller branches divaricate again in the ſame manner into foot-ſtalks, which are two inches long, each ſuſtaining one flower. At each of theſe joints is a ſpathe embracing the ſtalk, theſe at the lower joints are three inches long, but at the upper not more than one inch, ending in acute points and permanent; the flowers are of a yellow colour within, and variegated with dark red ſpots; the outſide is of an Orange colour. Theſe appear in july and auguſt, and in warm ſeaſons are ſucceeded by ſeeds.

[It is a native of the Eaſt Indies, China, Cochinchina and Japan. Cultivated by Mr. Miller in 1759 [t].

The Indians conſider it as an antidote to poiſons in general, and regard the bruiſed root as peculiarly efficacious in curing the bite of the ſerpent called Cobra de Copella [u].

[r] Thunberg, diſſ. [s] Thunb. jap. [t] Hort. kew. [u] Hort. malab.

39 to 54. The remaining ſpecies are taken from the rich Catalogue of Mr. Saliſbury's botanic garden at Chapel-Allerton, publiſhed by himſelf. Of theſe he has given no deſcriptions, but only copious ſpecific diſtinctions.—They are all natives of the Cape.

39. Corolla violet-coloured, limb three-fourths longer than the tube.

40. Border of the corolla one and one-third longer than the tube.

41. Border of the corolla four-ſevenths longer than the tube. Colour white with a green baſe.

42. Border of the corolla one and a half longer than the tube. Herb bright green, ſmooth, rigid [a].

43. Leaves all radical, a foot long, enſiform, ſtriated, ſmooth, quite entire, withering at the tip. Scape almoſt two feet high, round, ſlender, many-flowered, ſometimes branched. Spathe ſmall, two-leaved. Corolla deeply ſix-parted; ſegments ovate-oblong, obtuſe, roſe-purple coloured, with a deep purple baſe [b].

The limb of the corolla is longer by half than the tube.

44. Limb of the corolla as long again as the tube [c].

45. Leaves all radical, very long, linear, graſs-like, ſmooth, glaucous green. Scape three or four feet high and more, round, ſimple. Flowers peduncled, and forming a denſe pyramidal ſpike [d]. Border of the corolla three times longer than the tube [b], deeply ſix-parted, green or blue-green, with a dark-purple baſe. It flowers from may to auguſt [e].

46. Limb of the corolla five times longer than the tube. Colour deep red.

47. Corolla vermilion-coloured with a variegated ſtar at the baſe: limb twice as long as the tube.

48. Corolla orange-coloured with a dark baſe. Limb one-third longer than the tube.

49. Corolla pale yellow: limb longer by half than the tube.

50. Limb of the corolla the ſame length with the tube.

51. This ſpecies is ſingular in its almoſt total want of a tube, but in other reſpects it has the characters of this genus.

52. This has its name from its flowering very ſlowly in our ſtoves. The limb of the corolla is ſix times longer than the tube.

53. Limb of the corolla three and a half longer than the tube.

54. Limb of the corolla three and a half longer than the tube.

The three laſt ſpecies, with the *crocata*, *ſqualida*, and *deuſta*, are very nearly allied, and ſeem to be produced from a mixture with each other [a].

Numerous as the above liſt of Ixias is, there are many more ſpecies not yet determined, beſides numberleſs varieties.]

Several flowered many years ſince in the Chelſea garden: one purple on the outſide and white within; another with white flowers, having a blue ſtripe on the outſide of each petal; a third white with yellow bottoms; beſides many more raiſed from ſeeds. More than thirty ſorts or varieties are mentioned in a catalogue of Herman's. The roots of moſt, if not all the ſorts are frequently eaten by the inhabitants at the Cape of Good Hope.

PROPAGATION AND CULTURE.

Several of the Ixias ripen their ſeeds here, and may be propagated that way, by ſowing the ſeeds in pots, and plunging them into a moderate hot-bed, which will bring up the plants much ſooner than when they are ſown in the full ground; when the plants are fit to remove, they ſhould each be ſet in a ſmall pot filled with light earth, and if they are placed under a frame till they have taken good root, it will greatly forward their growth. Afterwards they may be placed in the open air in a ſheltered ſituation, where they may remain till the autumn, when they muſt be placed under a frame to ſcreen them from froſt. In the ſpring the plants may be turned out of the pots, and planted in a warm border, where they will abide through common winters very well; but in ſevere froſts they are often killed, unleſs they are covered with tan, or ſome other covering; a few therefore of the plants ſhould be kept in pots, and ſheltered under a frame or in a dry ſtove in winter.

They multiply very faſt by offſets, ſo that when they are once obtained, there will be no occaſion to raiſe them from ſeeds. Moſt of them will thus flower the enſuing ſeaſon; whereas thoſe from ſeeds are three or four years before they flower.

The ſtalks and leaves of theſe plants decaying to the root in autumn, the roots in borders ſhould then be covered two or three inches thick with tan, to keep them from froſt, and alſo from mice, who are very fond of them. The ſpring, before the roots ſhoot, is the beſt time to remove and part them; but this ſhould not be done oftener than every third year, for when they are oftener parted they will be weak and not flower well.

Ixora parviflora.

Vahl symb. 3. 11. *t.* 52.

Leaves subsessile lanceolate-oblong, panicle terminating.]

DESCRIPTIONS, &c.

1. Stem woody, five or six feet high, sending out many slender branches covered with a brown bark. Leaves opposite or three or four at a joint. Flowers terminating in clusters; they have very long slender tubes, are cut into four ovate segments, and are of a deep red colour.

[According to Loureiro's description, the stem is shrubby, manifold, upright, three feet high. Leaves ovate, quite entire, opposite, smooth, sessile not embracing. Flowers scarlet, fascicle-cymed, sastigiate, terminating. Corolla salver-shaped rather than funnel-shaped, with a very long slender tube, and a small equally quadrifid limb. Calyx very small, quadrifid, of the same colour with the corolla. Style longer than the tube; with an oblong, bifid stigma. Filaments very short at the mouth of the tube, with oblong anthers.

Gærtner describes the berry as fleshy, ovate-globular, crowned with the four upright acuminate teeth of the calyx, black, two-celled: cells, clothed with their proper white membrane, entirely separate from the seeds. Receptacle a fleshy substance adhering to the perforation of the partition, and diffused over the whole internal surface of the seed. Seed in each cell one, ovate-rounded, on one side convex smooth and naked; on the other slightly concave, covered with a spongy substance from the receptacle, ferruginous or rufescent.

Linneus and Adanson assign four seeds to the fruit, according to the Hortus Malabaricus. Gærtner could never discover more than two. Loureiro says, the berry is small, emarginate, crowned, two-celled with one seed in each cell, rounded on the outside, flat on the inner side. Gærtner refers to the Flamma sylvarum of Rumphius (4. t. 46.) which is not our plant. Loureiro thinks the description in p. 105 of that work not very different; but fig. 47, not 46, likely to be the plant.

Native of the East Indies, China, and Cochinchina. Introduced here in 1690, by Mr. Bentick[a]. Cultivated by Mr. Miller in 1768; and since by Dr. Fothergill at Upton, Mr. Thoburn, nurseryman at Brompton, &c.[b]]

2. Stem woody, six or seven feet high, sending out weak branches. Leaves opposite, sessile. Flowers terminating in small clusters; they have long slender tubes, divided into four segments at top, and are white, without scent.

[Stem, according to Loureiro, shrubby, branched, upright, three or four feet high. Leaves ovate-oblong, acute, quite entire, smooth, opposite, subsessile. Flowers white, fascicle-cymed, terminating. Berry, according to Gærtner, twin, broadest transversely, crowned with the four-toothed calyx, fleshy, two-celled, red. Receptacle pulpy, from the partition, filling the cavity of the seed. Seeds solitary, hemispherical-bullate.

Native of the East Indies and Cochinchina. Cultivated by Mr. Miller in 1768.]

3. This rises with a shrubby stalk four or five feet high, sending out slender branches opposite. Leaves oppofite, six inches long, two inches and a half broad, on short foot stalks. Flowers at the ends of the branches in a loose spike; they are white, and have a scent like Jasmin, whence in Jamaica and other islands of the West Indies, where this is a native, it is called Wild Jasmin. [The Wild Jasmin however of Jamaica is Pavetta? *t*, of Browne (142), which is the Coffea occidentalis of Linneus.

In the amoenitates academicæ it is said to be a tree, with the leaves in threes, on long petioles, lanceolate-ovate, smooth, quite entire, with a stipule to each petiole; the seed involved in an arillus, whence it is allied to the Coffea; the tube and border of the corolla much shorter than in the other Ixoras.

4, 5. Both natives of Jamaica[c].

6. Stem shrubby, upright, branched, four feet high. Leaves broader at the end, blunt, cordate at the base, quite entire, smooth, oppofite, subsessile. Flowers terminating, scarlet. These and the fruit of the same form with the two first species, and perhaps only a variety.

7. This is a large climbing branched unarmed shrub. Leaves ovate-lanceolate, quite entire, nine-nerved, subsessile, oppofite. Flowers white, terminating, in hemispherical cymes. Tube of the corolla slender and very long; border quadrifid. Stamens above the throat. Stigma ovate, bifid. Berry inferior, two-celled, one-seeded.

8. This also is a large climbing branching unarmed shrub. Leaves lanceolate, nine-nerved, quite entire, hairy, subsessile, oppofite. Flowers violet-coloured in axillary cymes; with the corolla and calyx quadrifid. Berry inferior, two celled, with one ovate rough seed in each cell.—These three are natives of Cochinchina[d].

9. Branches smooth, jointed, round at bottom but compressed at top. Leaves on very short petioles, oppofite, from two to three inches in length, very smooth, shining above, veined, quite entire, acute. Stipule on each side short, acuminate. Panicle a hand in length, brachiate. Partial peduncles oppofite, remote, with a small leaf at the base of each, three-parted with the branches three-parted again; the last pedicels in bundles. Flowers scarlet (white). Calyx minute, with four blunt teeth. Corolla funnel-form: tube filiform, a little thicker at top; border four-cleft; segments linear, blunt. Stamens a little longer than the corolla. Style the length of the tube of the corolla, when examined by a magnifier appearing to have hairs thinly scattered over it. Stigma emarginate.

It is allied to I. coccinea (next to which it ought to be placed), but the flowers are only one-fourth of the size, and disposed in racemed elongated corymbs. The leaves in I. coccinea are sessile not embracing, and it varies with the segments of the corolla subovate and blunt, or lanceolate and acute.—Native of the East Indies[e].]

PROPAGATION AND CULTURE.

These plants are propagated by seeds, when they can be procured from the countries where they grow naturally, for they do not perfect any seeds in England. They should be sown in small pots as soon as they arrive, and plunged into a hot-bed; if they arrive in autumn or winter, the pots may be plunged in the tan-bed in the stove, between the other pots of plants, so will take up little room; but when they arrive in the spring, it will be best to plunge them in a tan-bed under frames; the seeds will sometimes come up in about six weeks, if they are quite fresh; otherwise they will lie in the ground four or five months, and sometimes a whole year, therefore the earth should not be thrown out of the pots till there is no hopes of their growing; when the plants come up, and are fit to remove, they should be each planted in a separate small pot, filled with light earth, and afterwards treated in the manner directed for the Coffee-tree.

They may also be increased by cuttings during the summer months, and planted in small pots planted into a moderate hot-bed, covering them close either with bell or hand-glasses to exclude the external air, shading them carefully from the sun during the heat of the day, until they have put out good roots, when they should be parted, and each put into a separate pot, treating them as the seedling plants.

[Mr. Curtis remarks, that it is customary in this country to treat the Ixora as a stove plant; but that it may perhaps be less tender than we are aware of.]

[a] Hort. kew. [b] Curtis. [c] Swartz. [d] Loureiro. [e] Vahl.

END OF THE FIRST VOLUME.

EXPLANATION

OF THE

BOTANICAL PLATES.

PLATE I.

ROOTS.

THE Root is properly that organ of a vegetable by which it draws in nouriſhment, and which produces the herb with the fructification. It is uſually compoſed of *Medulla* or Pith, Wood, *Liber* or inner Bark, and *Cortex* or outer Bark: and it conſiſts of the *Caudex*, ſtock or main body; and the *Radicles* or Fibres. See *fig.* 2.

FIG. 1. Fuſiform or Spindle-ſhaped root. Simple and tapering to a point. Illuſtrated by the *Radiſh*. Carrot, Parſnep, &c. are other familiar inſtances.—This is alſo a *Perpendicular* root, in oppoſition to that which ſpreads horizontally, as in *fig.* 3.—And *Simple* in oppoſition to branched.

FIG. 2. Præmorſe or End-bitten. Not tapering, but ending blunt, and thus appearing as if bitten off ſhort at the end: as in *Scabious*, *Plantain*, *Valerian*.

FIG. 3. Creeping root. *Repens*. Spreading horizontally, and putting forth fibres at the joints, *a. a.* As in *Mint*, *Quick-graſs*, &c.—The upper part of this figure exhibits a Toothed or Scaly root.

FIG. 4. A Tuberous or knobbed root; conſiſting of roundiſh fleſhy bodies, called *Tubers*, connected to the ſtock in a bunch by intervening threads; and either terminated by fibres, as in the *Peony* which is repreſented here, or having them iſſuing from the eyes, as in the *Potatoe*. Other inſtances of the Tuberous root, are *Hemerocallis*, *Filipendula*, and *Jeruſalem Artichoke*.

FIG. 5. Palmate root. Conſiſting of ſeveral oblong tubers or knobs, ſpreading out like the fingers: as in ſome ſorts of *Orchis*.

FIG. 6. Teſticulate root. Compoſed of two roundiſh or oblong tubers: as in other ſpecies of *Orchis*.

FIG. 7. Solid root. Of one fleſhy uniform ſubſtance, as in the *Turnep* here repreſented both entire and cut tranſverſely. It is in reality a ſingle roundiſh Tuber, with fibres iſſuing from the baſe.

FIG. 8. Granulate root. Conſiſting of many little tubers or fleſhy knobs, reſembling grains of corn: as in *Saxifraga* hence called *granulata*; here repreſented.

Theſe are all *Solid* roots, except fig. 3. which is *Fibrous*. Moſt of the Graſſes have roots conſiſting wholly of fibres.

FIG. 9 and 10. Are not properly Roots but Hybernacles, in which the embryo of the future plant is incloſed by a ſcaly covering, and ſecured from external injuries during the winter.

FIG. 9. A tunicated or coated Bulb, repreſented both whole and cut tranſverſely.

FIG. 10. A ſcaly Bulb; repreſented by the *Lily*.

PLATE II.

SIMPLE LEAVES.

Simple leaves have one leaf only on a petiole or foot-ſtalk, or proceeding from the ſame point. They are very numerous; ſome are obvious from their names or definitions, and others are better deſcribed than figured. The figures are drawn from real leaves.

FIG. 1. Ovate, or egg-ſhaped leaf. A longitudinal ſection of an egg. The longitudinal diameter exceeding the tranſverſe; and the baſe wider than the top. Exemplified in *Viburnum Tinus*.

FIG. 1. β. Ovate-oblong leaf. *Hypericum calycinum*. This ſhews the veins and midrib very diſtinctly.

FIG. 1. γ. Obovate leaf. *Saxifraga umbroſa*. This ſhews the Retuſe, and alſo the Crenate leaf.

FIG. 2. Oval leaf. Agreeing with the Ovate in having the longitudinal diameter exceeding the tranſverſe; but differing in having the ſame curvature at both ends. *Saxifraga craſſifolia*.

FIG. 3. Elliptic leaf. The Oval leaf is a real ellipſis; but Botaniſts by an Elliptic leaf underſtand one that is much longer in proportion to its breadth, or more eccentric than the oval. *Saponaria officinalis* repreſented in this figure is called an elliptic-lanceolate leaf.

FIG. 4. Spatulate. Copied from Linneus. Fig. 1. γ. gives a tolerable idea of the Spatulate or Battledore-ſhaped leaf.

FIG. 5. Wedge-ſhaped. *Cuneiforme*. The longitudinal diameter exceeding the tranſverſe, and narrowing

narrowing gradually downwards. *Hibiſcus ſyriacus.*

FIG. 6. Lanceolate. Like the head of a lance or ſpear. Oblong, and gradually tapering towards each extremity. *Amygdalus Perſica* or *Peach.*

FIG. 7. Linear. Long and narrow, of the ſame breadth throughout, except at one or both ends. *Graſs.*

The aceroſe differs not from the Linear in form, but only in being permanent. As the Scotch Fir.

FIG. 8. Subulate or Awl-ſhaped. Linear at bottom, but gradually tapering towards the end, to a fine point: as in the *Pink.*—This ſhews a Lineate leaf, or one ſlightly marked with parallel lines. *Folium lineatum*; which muſt not be confounded with *Folium lineare.*

FIG. 9. Deltoid or Rhomboid leaf. *Lombardy Poplar.*

FIG. 10. Reniform or Kidney-ſhaped. The ſection of a kidney. Roundiſh, hollowed at the baſe without angles. *Glecoma hederacea* or *Ground Ivy.*—This is a very good inſtance of a Crenate leaf.

FIG. 11. Cordate or Heart-ſhaped. The longitudinal ſection of the heart. Ovate or ſubovate, hollowed at the baſe without angles. *Pelargonium cordatum.* This figure ſhews the ramifications of the veins.

FIG. 11. β. Cordate-orbicular. Hollowed at the baſe without angles, but nearly round; that is, if one leg of a pair of compaſſes were placed in the centre of the leaf, the other leg would ſweep over the tips of the incifures. *Pelargonium zonale,* ſo called from a zone of a darker colour encircling the leaf. Hence in Engliſh *Horſe-ſhoe Geranium.*

FIG. 12. Lunulate or Creſcent-ſhaped. Roundiſh, hollowed at the baſe, with poſterior angles. Copied from Linneus.

FIG. 13. Sagittate. Shaped like the head of an arrow. Triangular, hollowed at the baſe, with poſterior angles. *Sagittaria ſagittifolia.* This leaf is nerved, not veined.

FIG. 13. β. Sagittate-truncate. Arrow-headed, but cut off at the baſe, inſtead of being lengthened to a point. A leaf of *Convolvulus ſepium* is here repreſented.

FIG. 14. Haſtate. Reſembling the head of a Halbert. Triangular, hollowed at the baſe and at the ſides, with the angles ſpreading. *Convolvulus arvenſis.*

FIG. 15. Panduræform. Viol-ſhaped. Oblong, contracted on the ſides, like the body of a violin. Exemplified in *Convolvulus panduratus* and *Rumex pulcher.* The latter is here figured. Compare this with Lyrate, *fig.* 20.

FIG. 16. Lobate or Lobed. Divided to the middle into parts diſtant from each other, with convex margins.—Theſe leaves are named from the number of their diviſions, bilobate or two-lobed, trilobate or three-lobed, &c. The latter is here repreſented by a leaf of *Anemone Hepatica.* —For the Cloven leaf, *fiſſum,* ſee *fig.* 23.

FIG. 17. Palmate or Hand-ſhaped. Reſembling the hand with the fingers ſpread. Divided beyond the middle into ſeveral (uſually five) nearly equal parts: as in *Paſſiflora cærulea* here figured. The *Cirrus* or Tendril is here repreſented.—The *Digitate* leaf (t. 3. f. 3.) reſembles the fingers ſpread without the hand, and has the leaflets ſeparate; whereas in the *Palmate* they cohere at the baſe.

FIG. 18. Pinnatifid. Divided tranſverſely by oblong horizontal ſegments or jags, not extending to the midrib: as in *Thlaſpi Burſa Paſtoris* or common Shepherd's-pouch here figured.—Compare this with the Pinnate leaves in the next Plate.

FIG. 19. Runcinate. A ſort of Pinnatifid leaf, with the diviſions convex before, and ſtraight behind, ſomewhat reſembling the teeth of the large croſs-cut ſaw uſed in ſawing timber, in Latin *Runcinâ,* according to Linneus. The leaf of *Leontodon Taraxacum* or common *Dandelion* is here figured as an inſtance.

FIG. 20. Lyrate. Like the body of a violin with the ſtops. Divided tranſverſely into ſeveral jags, the lower ones remote and much ſmaller than the upper one. *Eryſimum Barbarea* or *Winter Creſs* is here figured.

FIG. 21. Laciniate or Jagged. Divided irregularly, and the parts ſubdivided indeterminately. Copied from Linneus.

FIG. 22. Sinuate. Having wide curved breaks in the margin, like ſinuſes or bays: as in the Oak leaf, here figured.

FIG. 23. Parted. Divided almoſt down to the baſe. According to the number of diviſions called Bipartite or Two-parted, Tripartite or Three-parted, &c.—The leaf here figured (*Ranunculus acris*) is *Three-parted,* and each part is generally trifid, or has three linear ſinuſes, with ſtraight margins.

Folium fiſſum, lobatum and *partitum* are thus diſtinguiſhed. The firſt and ſecond are divided to about the middle, the former with ſtraight, the latter with convex margins. The third is divided almoſt to the baſe.

FIG. 24. Truncate. Ending in a tranſverſe line, ſo that it ſeems as if the top of the leaf had been cut off. The *Tulip-tree,* here figured, is a remarkable inſtance of the Truncate or Lopped leaf, as Dr. Withering names it.

FIG. 25. Emarginate or End-nicked. Having an acute notch at the end: as is frequently the caſe in the leaves of the Laurel (*Prunus Laurocerafus.*) —A *Retuſe* leaf ends in a blunt ſinus.—And a *Præmorſe* leaf ends very obtuſely, with unequal notches.

FIG. 26. Acuminate, or ſharp-pointed. Drawn out into an awl-ſhaped point at the end: as in *Lamium album* here figured. It is a good inſtance of the *Serrate* leaf. See *fig.* 28.

The *Acute* leaf merely ends in an acute angle, and is oppoſed to obtuſe or blunt.

FIG. 27. Spiny or Thorny. Running out at the edge into hard, ſtiff, ſharp points: as in the leaf of Holly, here figured.—Oppoſed to Unarmed, *inerme.*

FIG. 28. Serrate. Toothed like a ſaw. Having

ſharp notches about the edge, pointing towards the extremity. When they have not this direction a leaf is merely ſaid to be toothed, *dentatum*. The Crenate leaf has blunt or circular teeth or notches. See *fig.* 10.—The Serrate leaf is repreſented in *fig.* 26.—The *Elm* leaf here figured is *Doubly Serrate*; that is, has large teeth, with ſmall ones upon each.

FIG. 29. Repand. With a flexuoſe or ſerpentine margin: as in *Solanum repandum*, here figured.—To be carefully diſtinguiſhed from the *waving* leaf: the curvature in that reſpecting the diſk; but in this the edge only.

FIG. 30. Eroſe. Having the appearance of being gnawed by inſects. Linneus deſcribes it as a ſinuate leaf, having other very ſmall obtuſe ſinuſes on its edge. The figure is copied from *Philoſ. Bot.*—White Muſtard furniſhes an inſtance.

When a leaf has no ſinus, it is ſaid to be entire, *Integrum*: when it has no notches, but the edge is one uniform curve, it is then ſaid to be quite entire, *Integerrimum*.

FIG. 31. Peltate, or Target-ſhaped. Having the petiole, leaf-ſtalk, or foot-ſtalk inſerted into the diſk of the leaf, inſtead of the edge or baſe, as is moſt uſual, *Tropæolum majus*.

FIG. 32. Nerved. Having veſſels perfectly ſimple and unbranched, extending from the baſe towards the tip: as in *Plantago* or *Plantain* here figured.—It may alſo ſerve for an inſtance of the *Folium integerrimum*.

PLATE III.

COMPOUND LEAVES.

Compound leaves have two or more leaves proceeding from one petiole. The component leaves are called Leaflets, *Foliola*.

FIG. 1. Binate leaf. Having a ſimple petiole connecting two leaflets: as in *Bauhinia* here figured. Linneus conſiders this as one ſpecies of the Digitate leaf.

FIG. 2. Ternate. Having three leaflets on a ſimple petiole: as in *Trifolium* or *Trefoil*, ſo named from this circumſtance. The leaf here figured belongs to *Medicago arabica*.

Linneus makes this alſo a ſpecies of Digitate.

FIG. 3. Digitate. Having ſeveral diſtinct leaflets connected by a ſimple petiole, uſually five or thereabouts; ſometimes more, as in the Horſe Cheſtnut. When the leaflets are regularly five, this leaf is generally called *Quinate*. The leaf here figured belongs to *Cannabis* or *Hemp*.

FIG. 4. Pedate, or Bird-footed as Dr. Withering names it. Having a bifid petiole connecting ſeveral leaflets, on the inſide only; as in *Helleborus niger* here figured.

FIG. 5. to 10. Pinnate leaves. Having ſeveral leaflets on each ſide of a ſimple petiole. Of this there are ſeveral varieties.

FIG. 5. Unequally pinnate. Terminated by a ſingle or odd leaflet. *Paſtinaca ſativa*. Parſnep.

FIG. 6. Abruptly pinnate. Conſiſting of pairs of leaflets, not terminated either by leaflet or tendril.

FIG. 7. Alternately pinnate. Having the leaflets ranged alternately along the common petiole. In the two former figures they are oppoſite.—This is alſo an inſtance of the Cirrhoſely pinnate leaf; being terminated by a tendril. *Vicia ſativa*, common Vetch or Tare.

FIG. 8. Interruptedly pinnate. Having ſmaller leaflets interpoſed between the principal ones: as in *Agrimonia Eupatoria* here figured.

FIG. 9. Decurſively pinnate. When the leaflets run into one another along the common petiole.

FIG. 10. Articulately or jointedly pinnate. When the common petiole is jointed.

FIG. 11. Conjugate. Having only one pair of leaflets: as in *Lathyrus odoratus* or Sweet Pea, here figured; accompanied by a branching tendril.

The two next are *Decompound* leaves; that is, the primary petiole is ſo divided, that each part forms a compound leaf. Thus in *fig.* 12. each part is ternate; and in *fig.* 13. each part is pinnate.

FIG. 12. Biternate. When a petiole has three ternate leaflets: as in *Epimedium*.

FIG. 13. Bipinnate. When the common petiole has pinnate leaves on each ſide of it: as in many of the Ferns.

The two next are *Super-decompound* leaves; that is, the common petiole divides ſeveral times, and connects many leaflets; each part forming a Decompound leaf.

FIG. 14. Triternate, or Triply-three fold. When a petiole has three biternate leaves:

FIG. 15. Tripinnate. When a petiole has bipinnate leaves ranged on each ſide of it: as in common Fern, *Pteris aquilina*.

FIG. 17. Frond. *Frons* in Latin ſignifies the twig of a tree with its leaves. Linneus applies this term to the peculiar leafing of Palms and Ferns. He explains it to be a kind of trunk or ſtem, which has the branch united with the leaf, and frequently with the fructification. The Frond of a *Palm* is here figured. Fig. 13 and 15 repreſent the Frond of Ferns.

The remaining figures explain the *Determination* of leaves; from their place, ſituation, inſertion or direction.

I. The *Place* which they occupy on a plant.

1. *Seminal* or Seed-leaves: being the lobes of the the ſeed expanded. *fig.* 19. *a*.

2. *Radical* or Root-leaves: proceeding immediately from the root, or growing next the ground; commonly different from the other leaves. *fig.* 19. *b*.

3. *Cauline*

narrowing gradually downwards. *Hibiſcus ſyriacus.*

FIG. 6. Lanceolate. Like the head of a lance or ſpear. Oblong, and gradually tapering towards each extremity. *Amygdalus Perſica* or *Peach.*

FIG. 7. Linear. Long and narrow, of the ſame breadth throughout, except at one or both ends. *Graſs.*

The aceroſe differs not from the Linear in form, but only in being permanent. As the Scotch Fir.

FIG. 8. Subulate or Awl-ſhaped. Linear at bottom, but gradually tapering towards the end, to a fine point: as in the *Pink.*—This ſhews a Lineate leaf, or one ſlightly marked with parallel lines. *Folium lineatum*; which muſt not be confounded with *Folium lineare.*

FIG. 9. Deltoid or Rhomboid leaf. *Lombardy Poplar.*

FIG. 10. Reniform or Kidney-ſhaped. The ſection of a kidney. Roundiſh, hollowed at the baſe without angles. *Glecoma hederacea* or *Ground Ivy.*—This is a very good inſtance of a Crenate leaf.

FIG. 11. Cordate or Heart-ſhaped. The longitudinal ſection of the heart. Ovate or ſubovate, hollowed at the baſe without angles. *Pelargonium cordatum.* This figure ſhews the ramifications of the veins.

FIG. 11. β. Cordate-orbicular. Hollowed at the baſe without angles, but nearly round; that is, if one leg of a pair of compaſſes were placed in the centre of the leaf, the other leg would ſweep over the tips of the inciſures. *Pelargonium zonale*, ſo called from a zone of a darker colour encircling the leaf. Hence in Engliſh *Horſe-ſhoe Geranium.*

FIG. 12. Lunulate or Creſcent-ſhaped. Roundiſh, hollowed at the baſe, with poſterior angles. Copied from Linneus.

FIG. 13. Sagittate. Shaped like the head of an arrow. Triangular, hollowed at the baſe, with poſterior angles. *Sagittaria ſagittifolia.* This leaf is nerved, not veined.

FIG. 13. β. Sagittate-truncate. Arrow-headed, but cut off at the baſe, inſtead of being lengthened to a point. A leaf of *Convolvulus ſepium* is here repreſented.

FIG. 14. Haſtate. Reſembling the head of a Halbert. Triangular, hollowed at the baſe and at the ſides, with the angles ſpreading. *Convolvulus arvenſis.*

FIG. 15. Panduræform. Viol-ſhaped. Oblong, contracted on the ſides, like the body of a violin. Exemplified in *Convolvulus panduratus* and *Rumex pulcher.* The latter is here figured. Compare this with Lyrate, *fig.* 20.

FIG. 16. Lobate or Lobed. Divided to the middle into parts diſtant from each other, with convex margins.—Theſe leaves are named from the number of their diviſions, bilobate or two-lobed, trilobate or three-lobed, &c. The latter is here repreſented by a leaf of *Anemone Hepatica.*—For the Cloven leaf, *fiſſum*, ſee *fig.* 23.

FIG. 17. Palmate or Hand-ſhaped. Reſembling the hand with the fingers ſpread. Divided beyond the middle into ſeveral (uſually five) nearly equal parts: as in *Paſſiflora cœrulea* here figured. The *Cirrus* or Tendril is here repreſented.—The *Digitate* leaf (t. 3. f. 3.) reſembles the fingers ſpread without the hand, and has the leaflets ſeparate; whereas in the *Palmate* they cohere at the baſe.

FIG. 18. Pinnatifid. Divided tranſverſely by oblong horizontal ſegments or jags, not extending to the midrib: as in *Thlaſpi Burſa Paſtoris* or common Shepherd's-pouch here figured.—Compare this with the Pinnate leaves in the next Plate.

FIG. 19. Runcinate. A ſort of Pinnatifid leaf, with the diviſions convex before, and ſtraight behind, ſomewhat reſembling the teeth of the large croſs-cut ſaw uſed in ſawing timber, in Latin *Runcina*, according to Linneus. The leaf of *Leontodon Taraxacum* or common *Dandelion* is here figured as an inſtance.

FIG. 20. Lyrate. Like the body of a violin with the ſtops. Divided tranſverſely into ſeveral jags, the lower ones remote and much ſmaller than the upper one. *Eryſimum Barbarea* or *Winter Creſs* is here figured.

FIG. 21. Laciniate or Jagged. Divided irregularly, and the parts ſubdivided indeterminately. Copied from Linneus.

FIG. 22. Sinuate. Having wide curved breaks in the margin, like ſinuſes or bays: as in the Oak leaf, here figured.

FIG. 23. Parted. Divided almoſt down to the baſe. According to the number of diviſions called Bipartite or Two-parted, Tripartite or Three-parted, &c.—The leaf here figured (*Ranunculus acris*) is *Three-parted*, and each part is generally trifid, or has three linear ſinuſes, with ſtraight margins.

Folium fiſſum, *lobatum* and *partitum* are thus diſtinguiſhed. The firſt and ſecond are divided to about the middle, the former with ſtraight, the latter with convex margins. The third is divided almoſt to the baſe.

FIG. 24. Truncate. Ending in a tranſverſe line, ſo that it ſeems as if the top of the leaf had been cut off. The *Tulip-tree*, here figured, is a remarkable inſtance of the Truncate or Lopped leaf, as Dr. Withering names it.

FIG. 25. Emarginate or End-nicked. Having an acute notch at the end: as is frequently the caſe in the leaves of the Laurel (*Prunus Lauroceraſus.*)—A *Retuſe* leaf ends in a blunt ſinus.—And a *Præmorſe* leaf ends very obtuſely, with unequal notches.

FIG. 26. Acuminate, or ſharp-pointed. Drawn out into an awl-ſhaped point at the end: as in *Lamium album* here figured. It is a good inſtance of the *Serrate* leaf. See *fig.* 28.

The *Acute* leaf merely ends in an acute angle, and is oppoſed to obtuſe or blunt.

FIG. 27. Spiny or Thorny. Running out at the edge into hard, ſtiff, ſharp points: as in the leaf of Holly, here figured.—Oppoſed to Unarmed, *inerme.*

FIG. 28. Serrate. Toothed like a ſaw. Having

ſharp notches about the edge, pointing towards the extremity. When they have not this direction a leaf is merely ſaid to be toothed, *dentatum*. The Crenate leaf has blunt or circular teeth or notches. See *fig.* 10.—The Serrate leaf is repreſented in *fig.* 26.—The *Elm* leaf here figured is *Doubly Serrate*; that is, has large teeth, with ſmall ones upon each.

FIG. 29. Repand. With a flexuoſe or ſerpentine margin: as in *Solanum repandum*, here figured.—To be carefully diſtinguiſhed from the *waving* leaf: the curvature in that reſpecting the diſk; but in this the edge only.

FIG. 30. Eroſe. Having the appearance of being gnawed by inſects. Linneus deſcribes it as a ſinuate leaf, having other very ſmall obtuſe ſinuſes on its edge. The figure is copied from *Philoſ. Bot.*—White Muſtard furniſhes an inſtance.

When a leaf has no ſinus, it is ſaid to be entire, *Integrum*: when it has no notches, but the edge is one uniform curve, it is then ſaid to be quite entire, *Integerrimum*.

FIG. 31. Peltate, or Target-ſhaped. Having the petiole, leaf-ſtalk, or foot-ſtalk inſerted into the diſk of the leaf, inſtead of the edge or baſe, as is moſt uſual, *Tropæolum majus*.

FIG. 32. Nerved. Having veſſels perfectly ſimple and unbranched, extending from the baſe towards the tip: as in *Plantago* or *Plantain* here figured.—It may alſo ſerve for an inſtance of the *Folium integerrimum*.

PLATE III.

COMPOUND LEAVES.

Compound leaves have two or more leaves proceeding from one petiole. The component leaves are called Leaflets, *Foliola*.

FIG. 1. Binate leaf. Having a ſimple petiole connecting two leaflets: as in *Bauhinia* here figured. Linneus conſiders this as one ſpecies of the Digitate leaf.

FIG. 2. Ternate. Having three leaflets on a ſimple petiole: as in *Trifolium* or *Trefoil*, ſo named from this circumſtance. The leaf here figured belongs to *Medicago arabica*.

Linneus makes this alſo a ſpecies of Digitate.

FIG. 3. Digitate. Having ſeveral diſtinct leaflets connected by a ſimple petiole, uſually five or thereabouts; ſometimes more, as in the Horſe Cheſtnut. When the leaflets are regularly five, this leaf is generally called *Quinate*. The leaf here figured belongs to *Cannabis* or *Hemp*.

FIG. 4. Pedate, or Bird-footed as Dr. Withering names it. Having a bifid petiole connecting ſeveral leaflets, on the inſide only; as in *Helleborus niger* here figured.

FIG. 5. to 10. Pinnate leaves. Having ſeveral leaflets on each ſide of a ſimple petiole. Of this there are ſeveral varieties.

FIG. 5. Unequally pinnate. Terminated by a ſingle or odd leaflet. *Paſtinaca ſativa*. Parſnep.

FIG. 6. Abruptly pinnate. Conſiſting of pairs of leaflets, not terminated either by leaflet or tendril.

FIG. 7. Alternately pinnate. Having the leaflets ranged alternately along the common petiole. In the two former figures they are oppoſite.—This is alſo an inſtance of the Cirrhoſely pinnate leaf; being terminated by a tendril. *Vicia ſativa*, common Vetch or Tare.

FIG. 8. Interruptedly pinnate. Having ſmaller leaflets interpoſed between the principal ones: as in *Agrimonia Eupatoria* here figured.

FIG. 9. Decurſively pinnate. When the leaflets run into one another along the common petiole.

FIG. 10. Articulately or jointedly pinnate. When the common petiole is jointed.

FIG. 11. Conjugate. Having only one pair of leaflets: as in *Lathyrus odoratus* or Sweet Pea, here figured; accompanied by a branching tendril.

The two next are *Decompound* leaves; that is, the primary petiole is ſo divided, that each part forms a compound leaf. Thus in *fig.* 12. each part is ternate; and in *fig.* 13. each part is pinnate.

FIG. 12. Biternate. When a petiole has three ternate leaflets: as in *Epimedium*.

FIG. 13. Bipinnate. When the common petiole has pinnate leaves on each ſide of it: as in many of the Ferns.

The two next are *Super-decompound* leaves; that is, the common petiole divides ſeveral times, and connects many leaflets; each part forming a Decompound leaf.

FIG. 14. Triternate, or Triply-three fold. When a petiole has three biternate leaves.

FIG. 15. Tripinnate. When a petiole has bipinnate leaves ranged on each ſide of it: as in common Fern, *Pteris aquilina*.

FIG. 17. Frond. *Frons* in Latin ſignifies the twig of a tree with its leaves. Linneus applies this term to the peculiar leafing of Palms and Ferns. He explains it to be a kind of trunk or ſtem, which has the branch united with the leaf, and frequently with the fructification. The Frond of a *Palm* is here figured. Fig. 13 and 15 repreſent the Frond of Ferns.

The remaining figures explain the *Determination* of leaves; from their place, ſituation, inſertion or direction.

I. The *Place* which they occupy on a plant.

1. *Seminal* or Seed-leaves: being the lobes of the the ſeed expanded. *fig.* 19. *a*.
2. *Radical* or Root-leaves: proceeding immediately from the root, or growing next the ground; commonly different from the other leaves. *fig.* 19. *b*.

3. *Cauline*

3. *Cauline* or Stem-leaves. Inſerted into the ſtem itſelf. *fig.* 19. *c. c.*
4. *Branch* leaves. Growing on the branches. *fig.* 19. *d.*
5. *Axillary.* At the angle formed by the branch with the ſtem; or inſerted at the baſe of a branch: as at the foot of the branch *d* in *fig.* 19.

II. *Situation* or Diſpoſition of leaves.

1. *Stellate* or *Verticillate.* Leaves in whorls, or radiating like the ſpokes of a wheel: not fewer than three, but commonly from four to ſix or eight. *fig.* 21. *b. c.*
2. *Oppoſite.* In pairs. *fig.* 18 and *fig.* 21. *d.*
3. *Alternate.* One above another, in a regular gradation. *fig.* 20. *b. c.*
4. *Jointed. Articulatum.* When one leaflet grows from the top of another. *fig.* 21. *a.*
5. *Faſcicled.* In bunches or bundles from the ſame point: as in *Larix* or Larch. *fig.* 16.

III. The *Inſertion* of leaves.

1. *Peltate.* Having the petiole inſerted into the diſk of the leaf. *t.* 2. *fig.* 31.
2. *Petioled.* Growing on a petiole, leaf-ſtalk or foot-ſtalk. Oppoſed to ſeſſile. *fig.* 20. *a.*
3. *Seſſile.* Cloſe to the ſtem or branch, without the intervention of a petiole. *fig.* 20. *b.*
4. *Decurrent.* Having the baſe extending downwards along the ſtem. *fig.* 20. *c.*
5. *Embracing* or *Stem-claſping. Amplexicaule.* Surrounding the ſides of the ſtem or branch at the baſe. *fig.* 20. *d.*
6. *Perfoliate.* Encircling the ſtem or branch, ſo that it ſeems as if it had been driven through the leaf. *fig.* 20. *e.*
7. *Connate.* Two leaves ſo united at their baſes as to have the appearance of being one leaf: as in the Garden Honeyſuckle. *fig.* 20. *f.*
8. *Sheathing. Vaginans.* Inveſting the ſtem or branch by its baſe. *fig.* 20. *g.*

IV. *Direction* of Leaves.

1. *Inflected* or Incurved. Bent upwards in a curve at the end towards the ſtem or branch. *fig.* 18. *a.*
2. *Erect.* Pointing upwards. *fig.* 18. *b.*
3. *Spreading. Patens.* Forming an acute angle with the ſtem or branch. *fig.* 18. *c.*
4. *Horizontal.* Making a right angle with the ſtem. *fig.* 18. *d.*
5. *Reclined.* Curved downwards, ſo that the apex is lower than the baſe. *fig.* 18. *e.*
6. *Revolute.* Rolled back or downwards. *fig.* 18. *f.*

PLATE IV.

FLOWER.

The *Fructification* conſiſts of the *Flower* and *Fruit.* The Flower has four parts—the *Calyx*, *Corolla* with its *Nectary*, *Stamen* and *Piſtil.*

I. Calyx. The outer covering of the Flower.

1. *Perianth* or Calyx properly ſo called: contiguous to the other parts of fructification. *fig.* 1. *a. Tradeſcantia virginica. fig.* 7. *b. fig.* 8. *b. fig.* 12. *b. fig.* 13. *b.*
2. *Involucre.* Remote from the flower, particularly in the Umbel. *fig.* 2, 3. *General. fig.* 2. *a. Partial. fig.* 3. *a. Fool's Parſley* and *Chervil.*
3. *Ament* or *Catkin.* Conſiſting of many chaffy ſcales, ranged along a common receptacle. *t.* 5. *fig.* 21, 22.
4. *Spathe.* A Sheath opening longitudinally. *fig.* 4. *b. Narciſſus Tazetta.*
5. *Glume.* The calyx of Corn and Graſſes; formed of valves (uſually two) embracing the ſeed. *fig.* 5. *a. a. Dactylis glomerata.*
6. *Calyptre.* The calyx of Moſſes. *t.* 6. *f.* 24.
7. *Volva.* The calyx of a Fungus. *t.* 6. *f.* 26.

II. Corolla. The inner covering of the Flower: uſually of a more tender texture, with a variety of ſplendid colours. *f.* 4. and *f.* 6—13. *a.*

Petal in a monopetalous flower, the ſame with the corolla, excluſive of the Nectary, *f.* 6, 7. It conſiſts of the *Tube* and *Limb* or Border. *f.* 7.

In a polypetalous corolla, the Petal is one of the leaves of which the whole corolla is compoſed. *fig.* 8. *a. fig.* 12. *a. fig.* 13. *a, c, d, e.* In conſiſts of the Claw, *unguis. f.* 12. *d.* and the *Lamina. f.* 12. *c.*

Campanulate or *Bell-ſhaped* Corolla. Monopetalous, ſwelling or bellying out, without any tube. *Convolvulus ſepium. fig.* 6.

Funnel-ſhaped. Infundibuliformis. Monopetalous, with a conical limb, and tubular baſe. *fig.* 7. *Nicotiana Tabacum.*

Salver-ſhaped. Hypocrateriformis. Monopetalous, with a flat limb riſing from a tube. *fig.* 8. *Jaſminum officinale.*

Wheel-ſhaped. Rotata. Monopetalous, ſpreading flat, without any tube. *Veronica Chamædrys. fig.* 9.

Labiate. Monopetalous, irregular, with the lips gaping. *fig.* 10. *Lamium album.*

Perſonate. Monopetalous, irregular, with the lips cloſed. *fig.* 11. *Antirrhinum majus.*

Cruciform. Polypetalous, with four equal petals, ſpreading out in form of a croſs. *fig.* 12.—*c.* the *Lamina* or border; *d.* the *Unguis*, claw or tail of the petal. *Cheiranthus incanus.*

Papilionaceous. Irregular, uſually four-petalled. Shaped like a Butterfly with its wings expanded. *fig.* 13. *Piſum ſativum. a.* Corolla. *b.* Calyx. *c. Vexillum*, Standard or Banner; the upper Petal, ſpreading and riſing upwards. *d.* The two wings, *Alæ*, the two ſide petals, ſtanding ſingly; being ſeparated by the Keel, *Carina*, *e*, the lower petal, ſhaped like a boat: this is ſometimes ſplit, and then the corolla is five-petalled.

Nectary.

Nectarium, the Nectary, or melliferous part of the

the flower; commonly making a part of the corolla, but ſometimes diſtinct from it. Linneus has extended the name of Nectary to ſome parts of the corolla which do not appear to ſecrete a honied juice.

The forms which the Nectary puts on are various. Some of the moſt remarkable are the *Cup*, in Polyanthus Narciſſus, *fig.* 4. *Fiſtulous* bodies, two in number, concealed under the helmet-petal or hood in Aconitum. *a, a. fig.* 14. One of them is repreſented ſeparately at *b*. *Horn* or *Spur* at the back of the flower, as at *a* in *fig* 15. repreſenting a flower of *Delphinium Ajacis* or Garden Larkſpur. No appearance of the Nectary is more common than that of *Glands*. In Ranunculus, *fig.* 16. it is in the form of one large *Gland*, *a* juſt above the baſe of each petal, on the inſide.

Parnaſſia paluſtris, fig. 17. has five ſingular nectaries, *b*. They are heart-ſhaped, furniſhed with hairs, upon the top of which are little balls.

Fritillaria imperialis or Crown Imperial, *fig.* 18. has a large excavation at the baſe of each petal, which generally exhibits a large drop of nectareous juice.

Hellebore has ſeveral tubular Nectaries, like ſmall bottles, placed in a ring round the baſe of the ſtamens. In *Helleborus foetidus fig.* 19. there are from five to eight of theſe. One is repreſented ſeparately at *a*.

Aſphodel has ſix valves, each inſerted into the baſe of one of the petals, and forming a complete arch over the germ. A ſtamen ſprings from each. One of theſe valves, with its ſtamen, is repreſented at *b*.—*Aſphodelus luteus* is here figured.

Stamen.

An organ or viſcus for the preparation of the pollen, *fig.* 1. *b. fig.* 5. *fig.* 17, 19 and 20. The Stamen conſiſts of two parts, the *Filament* and *Anther*. Theſe are very diſtinct in *fig.* 5. and 20. See alſo *Plate* 7.

Pistil.

Piſtillum, *Piſtil* or *Pointal*. An organ or viſcus for the reception of the pollen. *fig.* 1. *c*. It conſiſts of the *Germ*, *Style*, and *Stigma*. See *Plate* 8.

Germ is the rudiment of the fruit yet in embryo.—*Style* is the middle portion of the piſtil, connecting the ſtigma with the germ.—*Stigma* is the top of the piſtil, pubeſcent and moiſt, in order to detain and explode the pollen or prolifick powder. Theſe three parts are ſeen diſtinctly in *fig.* 1, 4, 15, 17, 19, of *Plate* 8.

PLATE V.

PERICARP or FRUIT.

A Viſcus big with ſeeds, which it drops when ripe. It is the germ fecundated, or arrived to a ſtate of maturity, after the flower is paſt; containing ripe ſeeds analogous to fruitful eggs.—The moſt remarkable pericarps are the *Capſule*, *Silique*, *Legume*, *Follicle*, *Drupe*, *Pome*, *Berry* and *Strobile*.

Capſule a membranaceous hollow pericarp, opening in ſome determinate manner; or, differently in different plants. *fig.* 1—5. The parts are 1. The Valves or outer covering. 2. The Partitions, *Diſſepimenta*. 3. The *Columella* or central pillar. 4. The Cells, *Loculamenta*. Theſe parts are eaſily diſtinguiſhed in *fig.* 2 and 3. The former repreſents a Capſule of *Iris* (which is figured entire in *f.* 1.) cut tranſverſely, ſo as to ſhew the three cells with the partitions dividing them, and the ſeeds lodged in them. The latter repreſents it burſt open, and exhibiting the three valves, with the ſeeds ranged along the Columella.

Capſules are diſtinguiſhed from the number of their valves and cells. This here figured is a three-valved, three-celled capſule.

Some flowers are ſucceeded by more capſules than one. Such fruits are called *Bicapſular*, &c. That here figured at *f.* 4. is the fruit of the *Aquilegia* or Columbine; and is *Quinquecapſular*. A ſingle capſule is repreſented ſeparately.

Capſules are called *Dicoccous* and *Tricoccous*, which ſwell out in two or three protuberances, and are divided internally into two or three cells, with one ſeed in each cell.—*Fig.* 5. exhibits two views of the ſeed-veſſel of the Tea-tree; the firſt entire, the ſecond opening. This is a *Tricoccous* capſule.

Siliqua, Silique or Pod. An oblong, membranaceous, two-valved pericarp, having the ſeeds faſtened along both ſutures. *fig.* 6. A pod of Stock-Gilliflower, ſhewing the two valves, the partition with its ſutures, and the ſeeds.

Silicula, Silicle or Pouch, differs from the Silique only in form and ſize; the tranſverſe diameter is equal, or nearly ſo, to the longitudinal. It varies in ſhape, as ſhewn by three figures at *n*. 7. *Biſcutella auriculata*, *Thlaſpi Burſa Paſtoris*, and *Draba verna*.

Legume, Pod or Cod. Two-valved, having the ſeeds faſtened along one ſuture only. Uſually membranaceous and one-celled. *fig.* 8. *a a*. The two valves. *Piſum ſativum*. Garden Pea.

Follicle or *Conceptacle*. One-valved, opening longitudinally on one ſide, and having the ſeeds looſe in it. It is uſually double or two pericarps together, and membranaceous. *fig.* 9. *Aſclepias*.

The following are *moiſt* Fruits.

Drupe or Plum. A pulpy pericarp or fruit, without valves, containing a nut or ſtone incloſing a kernel. Uſually moiſt and ſucculent; but ſometimes dry, as *Almond*.

Fig. 10. *a—e*. *Phoenix dactylifera* or Date Palm. *a*. The Drupe entire. *b*. The ſame opened longitudinally. *c*. The Stone, Nut, or *Putamen*. *d*. The umbilical chord by which it hangs. *e*. The bag in which the Stone is incloſed.

Fig. 10. *f—b*. *Myriſtica officinalis* or Nutmeg. *f*. The Fruit opened longitudinally. *g*. The Nut involved in its aril, which is called *Mace*. *b*. The fleſh covering the nut with its aril; of a ſolid texture drying

drying to a leathery cruſt. In Linneus's genera it is called a drupaceous capſule. Gærtner names it a Berry, but allows that it would be a Drupe, were it not for the Aril.

Pome. A pulpy pericarp or fruit, without valves, containing a capſule. It includes all the moiſt fruits which have the ſeeds lodged in a core. *Fig.* 11. *Achras Sapota.* The fruit is figured entire, and cut tranſverſely: the latter ſhews the granular pulp, and the four cells in each of which a ſeed is lodged; there are ten cells in the unripe fruit, but all except three or four are abortive.

Berry, Bacca. A ſucculent or pulpy pericarp or fruit, without valves, containing naked ſeeds either looſe in the pulp, or placed on receptacles: *fig.* 12. Many fruits are improperly called Berries: and ſome which Linneus has ſo named do not agree with the deſcription.

Fig. 13. repreſents a *Compound Berry*; each component part or *Acinus* being a ſmall berry, containing one ſeed immerſed in the pulp. *a.* The entire fruit. *b.* The calyx. *c.* The common receptacle with the compound berry diſſected. *Rubus fruticoſus* or Blackberry.

Gærtner has other pericarps: as——*Utriculus.* One-celled and one-ſeeded; commonly very thin and almoſt diaphanous; always valveleſs: as in *Beta, Thaliſtrum, Zannichellia.*

Samara. Membranaceous, one or two-celled, never opening ſpontaneouſly, ſpreading out into a leafy form: as in *Elm, Aſh, Birch, Maple,* &c. See *Plate* 6. *fig.* 10.

Pepo. A fleſhy fruit approaching to the Berry, but having cells remote from the axis, and ſo placed near the periphery of the fruit, that the ſeeds are faſtened to it. It comprehends the *Pompion, Melon, Cucumber,* &c. Linneus calls them Pomes; but this fruit is diſtinct both from that and the Berry.

Gærtner's elegant and accurate work, *De Fructibus & Seminibus,* may be conſulted on this ſubject to great advantage.

PLATE VI.

FRUIT, SEED AND RECEPTACLE.

Strobile. A Pericarp formed from a female Ament, by the hardening of the ſcales.—In *Philoſ. Botan.* it is explained to be a Receptacle covered with indurated calycine ſcales. *Fig.* 1. *Magnolia grandiflora,* with the ripe ſeeds hanging by threads from the ſcales.

Cone, a ſpecies of Strobile, according to Linneus. The fruit of many evergreen trees, as *Fir, Pine, Cedar, Cypreſs.* Compoſed of woody ſcales, uſually opening, and having a ſeed at the baſe of each ſcale. It is broadeſt at the baſe, and tapers more or leſs to the end. *Fig.* 2. An entire Cone. *Fig.* 3. One of the ſcales magnified, with the ſeeds.

Nut. A hard bony Pericarp, not opening in general ſpontaneouſly. Or a ſeed covered with a ſhell. This term extends to the Acorn. *fig.* 4, and to all Stone-fruits.

Seed the rudiment or Embryo of a new plant: or, the deciduous part of a vegetable, containing the rudiment of another vegetable of the ſame ſpecies, vivified by the pollen; and analogous to the egg in animals. *fig.* 5—10. It conſiſts of three principal parts—1. The tegument or ſkin. 2. The Cotyledons or lobes. 3. *Corculum* or heart. *Fig.* 5. repreſents a ſeed of Horſe-Cheſnut, entire at *d:* naked or ſtripped of the ſkin, ſhewing the embryo at *a. b, c.* is the ſame cut through, diſcovering two very thick lobes at *c*; and the embryo at *b,* with the plume emerging from the radicle.

Beſides theſe three parts common to all ſeeds, ſome have a *Hilum* or eye; which is a ſcar made by the umbilical chord, or the point of adheſion to the pericarp: *fig.* 5. *d.* Remarkable in the Bean, Kidney Bean, Cardioſpermum, &c.—An *Aril. Plate* 5. *f.* 3, 10.—A Coronet, *Coronula, fig.* 6—10. Which is either a *Calycle* or the calyx adhering, *fig.* 10.—a *Pappus* or Down, *fig.* 6, 7, 8, which is either ſimple, as in *f.* 6, 7, or feathered as in *f.* 8.—ſtiped, as in *f.* 6, or ſeſſile, as in *f.* 7.—a Wing, as in *fig.* 10. the lower row.—a Tail, as in *f.* 9, which is often ſpiral, and throws off the ſeed with conſiderable force. —Hooks, as in *fig.* 11.—Theſe and other proceſſes aſſiſt much in the diſperſion of ſeeds.

Receptacle. The Baſe by which the other parts of the fructification are connected: *fig.* 13, 14. *Fig.* 13. is a compound Receptacle; in the Dandelion: as it connects many florets. *Fig.* 14. is that of the Fruit, or rather of the Seeds, in the Strawberry: for the ſeeds are inſerted on the outſide of the pulp.

PLATE VII.

LINNEUS'S CLASSES, OR

The Outlines of LINNEUS's System of Vegetables.

A. Plants with conſpicuous Flowers.
B. 1. All complete, or furniſhed with Stamen and Piſtil.
C. With Stamens ſeparate from the Piſtil.
D. And ſeparate from each other.
E. All of the ſame length, or not proportionably longer than each other.
F. In which the number only is to be conſidered.
I. MONANDRIA. One Stamen. *Fig.* 1.
II. DIANDRIA. Two Stamens. *Fig.* 2.
III. TRIANDRIA. Three Stamens. *Fig.* 3.
IV. TETRANDRIA. Four equal Stamens. *Fig.* 4.
V. PENTANDRIA. Five Stamens. *Fig.* 5.
VI. HEXANDRIA. Six equal Stamens. *Fig.* 6.
VII. HEPTANDRIA. Seven Stamens. *Fig.* 7.
VIII. OCTANDRIA. Eight Stamens. *Fig.* 8.
IX. ENNEANDRIA. Nine Stamens. *Fig.* 9.
X. DECANDRIA. Ten Stamens. *Fig.* 10.
XI. DODECANDRIA. From 11 to 19 Stamens incluſive. *Fig.* 11.
F. In which the ſituation is alſo to be conſidered.
XII. ICOSANDRIA. About 20 Stamens on the Calyx or Corolla. *Fig.* 12.
XIII. POLYANDRIA. Twenty Stamens or more on the receptacle or baſe of the Flower. *Fig.* 13.
E. Some Stamens proportionably longer than others.
XIV. DIDYNAMIA. Four Stamens, two longer. One Piſtil. Flowers ringent. *Fig.* 14.
XV. TETRADYNAMIA. Six Stamens, four longer. One Piſtil. Flowers cruciform. *Fig.* 15.
D. Stamens coherent at bottom only, or by the Filaments.
XVI. MONADELPHIA. Filaments united into one body. *Fig.* 16.
XVII. DIADELPHIA. Filaments in two bodies. Corolla papilionaceous. *Fig.* 17.
XVIII. POLYADELPHIA. Filaments in 3 or more parcels. *Fig.* 18.
D. Stamens coherent at top only, or by the Anthers.
XIX. SYNGENESIA. Anthers united, 5 Filam. diſtinct, 1 Piſtil, Flowers compound. *Fig.* 19.
C. With Stamens growing out of the Piſtil itſelf.
XX. GYNANDRIA. Stamens on the Piſtil, not on the Receptacle. *Fig.* 20.
B. 2. All incomplete; or which have Stamens only, or Piſtils only.
XXI. MONOECIA. Each ſort of Flower ſeparate, but on the ſame Plant. *Fig.* 21.
XXII. DIOECIA. Each ſort of Flower, on diſtinct Plants only. *Fig.* 22.
B. 3. Flowers of the firſt ſort, together with one both of the ſecond ſort.
XXIII. POLYGAMIA. *Fig.* 23.
A. Flowers inconſpicuous.
XXIV. CRYPTOGAMIA. Flowers very ſmall, inviſible, or not yet diſcovered.
XXV. PALMS. Flowers borne on a *Spadix*, and within a *Spathe*, moſtly incomplete.

Linneus's Claſſification is explained at length in Letters on the Elements of Botany, letter 9.

PLATE VIII.

LINNEUS'S ORDERS.

The Orders in the firſt thirteen Claſſes of Linneus's Syſtem are founded wholly upon the number of Piſtils, and are entiled—

1. *Monogynia.* Such flowers as have one Piſtil: *fig.* 1.
2. *Digynia.* Two Piſtils: *fig.* 2.
3. *Trigynia.* Three Piſtils: *fig.* 3.
4. *Tetragynia.* Four Piſtils: *fig.* 4.
5. *Pentagynia.* Five Piſtils: *fig.* 5.
6. *Hexagynia.* Six Piſtils: *fig.* 6.
7. *Heptagynia.* Seven Piſtils: *fig.* 7.
8. *Decagynia.* Ten Piſtils: *fig.* 8.
9. *Dodecagynia.* Twelve Piſtils: *fig.* 9.
10. *Polygynia.* Many Piſtils, indefinite: *fig.* 10.
11. *Didynamia Gymnoſpermia.* Four naked ſeeds at the bottom of the perianth: *fig.* 11. wherein the four ſeeds are repreſented in their natural ſituation in the figure on the left hand; and in that on the right hand, the calyx is laid open to ſhew them more plainly.
12. *Didynamia Angioſpermia.* The ſeeds in a ſeed-veſſel; which is two-celled, and the ſeeds, which are ſmall and many, are faſtened to a receptacle in the middle of it. The flowers are commonly Perſonate. In the former Order they are Labiate or Ringent. They have only one Piſtil in both.
13. *Tetradynamia Siliculoſa.* Fruit a *Silicle*, or ſhort two-valved pericarp, varying in ſhape, triangular, oval, ſpherical, &c. *fig.* 13.
14. *Tetradynamia Siliquoſa.* Fruit a *Silique*, or oblong narrow two-valved pericarp. *fig.* 14. The ſeeds are faſtened along both ſutures, in this and the ſilicle. The flowers are Cruciform, and have only one piſtil in both orders.

In the 16th, 17th, and 18th Claſſes, *Monadelphia*, *Diadelphia*, and *Polyadelphia*, the Orders are taken from the number of ſtamens; it is unneceſſary therefore to figure them.

The 19th Claſs *Syngeneſia*, ſo called from having the anthers united in a cylinder, has ſix Orders, five founded on the form, ſex and ſituation of the Florets; which are either ligulate or tubulous; hermaphrodite, male, female or neuter; ſituated in the diſk or the ray. The flowers are Compound, having ſeveral florets on a common receptacle, and incloſed within a common perianth.

15. *Syngeneſia Polygamia Æqualis.* The whole flower regular, all the florets alike, either ligulate or tubulous; all hermaphrodite and conſequently fertile. *Fig.* 15. repreſents a compound ligulate flower; and a ſingle floret, ſhewing its ſhape, with the germ crowned by its pappus, the cylinder of anthers, with the bifid curled ſtigma above it.
16. *Polygamia Superflua.* Florets of the diſk hermaphrodite and tubulous; of the ray or exterior part female, commonly ligulate, but ſometimes tubulous, or even naked. Always fertile or producing ſeed both in diſk and ray. *Fig.* 16. repreſents a radiate flower, together with a ſingle tubulous and ligulate floret. This Order is named *Superflua*, becauſe the florets of the ray, though fertile, are not wanted.
17. *Polygamia Fruſtranea.* Florets tubulous hermaphrodite in the diſk, producing ſeed; but imperfect, abortive or fruſtrate in the ray; wanting at leaſt the ſtigma, but frequently neuter, as in *fig.* 17. where beſides the entire flower, a ſingle floret, both fertile and neuter is repreſented.
18. *Polygamia Neceſſaria.* Florets in the diſk or middle tubulous and male, or at leaſt defective, and therefore barren; whilſt thoſe of the ray or towards the outſide of the flower, though female, are fertile; being impregnated by the barren flowers, which are therefore neceſſary. *Fig.* 18. beſides the entire flower, repreſents a floret of each ſort, together with a fertile and abortive ſeed.
19. *Polygamia Segregata.* Beſides the common calyx, as in the foregoing Orders, this has partial calyxes incloſing one or ſeveral florets, thus ſeparated (ſegregata) into diſtinct parcels in a manner different from the other Orders. *Fig.* 19. beſides the whole flower repreſents a ſingle tubulous floret, both ſurrounded by its calyx, and ſtripped of it.

Theſe Orders are ſtyled *Polygamia*, becauſe the flowers have many florets, incloſed by one common perianth. In oppoſition to the laſt Order.

20. *Monogamia*, which conſiſts of *Simple* flowers: *fig.* 20. Linneus placed this Order here in conformity with the principles of his artificial ſyſtem, becauſe the Anthers are united; but it is to be lamented that he thus deformed a Claſs otherwiſe truly natural.

The Orders of the three following claſſes being founded upon the ſtamens, and taking their names from the foregoing claſſes, it is unneceſſary to explain or figure them.

21, 22. The 23d Claſs *Polygamia* has three Orders, from the triple mode in which the three ſorts of flowers may be arranged—on the ſame plant, *Monœcia*—on two plants, *Dioecia*—or on three ſeparate plants of the ſame ſpecies, *Trioecia*. *Fig.* 21, 22 repreſents a plant of the third Order, wherein the figure moſt to the right has male flowers only; that in the middle female flowers only; and that marked 21, hermaphrodite flowers only.
23. *Cryptogamia Filices.* Ferns. Having the fructification upon the back of the leaf. *fig.* 23. and *fig.* 24. *Plate* 7.
24. *Cryptogamia Muſci.* Moſſes, *fig.* 24.
25. *Algæ*, *fig.* 25.
26. *Fungi*, *fig.* 26.

See Letters on the Elements of Botany, letter 10.

EXEMPLIFICATION

OF

LINNÆAN CLASSES.

PLATE ONE TO PLATE SEVEN INCLUSIVE.

PLATE I. Exhibits the Claſſes Monandria, Diandria, Triandria, and Tetrandria.

FIG. 1. A ſmall ſprig of Lopezia racemoſa. (Monandria Monogynia.)

FIG. 2. A ſingle flower magnified.

FIG. 3. Flower of Canna Indica. (Monandria Monogynia.)

FIG. 4. The ſame with the calyx and lower parts removed.

FIG. 5. Hippuris vulgaris. (Monandria Monogynia.)

FIG. 6. and 7. Flowers of the ſame.

FIG. 8. Flower of Circæa Lutetiana. (Diandria Monogynia) in its natural ſize.

FIG. 9. The ſame magnified.

FIG. 10. A ſprig of Veronica Beccabunga. (Diandria Monogynia) in its natural ſize.

FIG. 11. Magnified flowers.

FIG. 12. Flowering ſpike of Anthoxanthum odoratum. (Diandria Digynia.)

FIG. 13. Magnified flower.

FIG. 14. Flower of Crocus vernus. (Triandria Monogynia) laid open.

FIG. 15. Flower of Moræa tripetala. (Triandria Monogynia.)

FIG. 16. Flowering ſpike of Cynoſurus criſtatus. (Triandria Digynia.)

FIG. 17. Separate unopened flowers.

FIG. 18. The ſame magnified.

FIG. 19. Magnified open flower.

FIG. 20. Part of a flowering panicle of Briza media. (Triandria Digynia.)

FIG. 21. Magnified flower of the ſame.

FIG. 22. Head or ſpikelet of unopened flowers, in their natural ſize.

FIG. 23. Flowering head of Scabioſa arvenſis. (Tetrandria Monogynia.)

FIG. 24. Single floret, magnified.

FIG. 24. Cuſcuta Europæa. (Tetrandria Monogynia.)

FIG. 26, 27. Separate flowers, both in their natural ſize and magnified.

FIG. 28. Sagina Ceraſtoides. (Tetrandria Tetragynia.)

FIG. 29. The ſeveral parts of the flower, with the ſeed-veſſel and ſeeds.

PLATE II. Exhibits the Claſſes Pentandria, Hexandria, and Heptandria.

FIG. 1. Azalea nudiflora. (Pentandria Monogynia.)

FIG. 2. Stamens and Style of the ſame.

FIG. 3. Hottonia paluſtris (Pentandria Monogynia,) with a view of Corolla, Calyx, Stamen, and Germ ſeparate.

FIG. 4. Mirabilis Jalapa. (Pentandria Monogynia.)

FIG. 5. Gentiana Amarella. (Pentandria Digynia.)

FIG. 6. Corolla, Calyx, and Germ ſeparate.

FIG. 7. Athamanta Libanotis. (Pentandria Digynia.) with a magnified view of the flower and germ.

FIG. 8. Parnaſſia paluſtris. (Pentandria Tetragynia.)

FIG. 9. Lilium Chalcedonicum. (Hexandria Monogynia.)

FIG. 10. Alſtroemeria Pelegrina. (Hexandria Monogynia.)

FIG. 11. Trillium erectum. (Hexandria Trigynia.)

FIG. 12. Trientalis Europæa. (Heptandria Monogynia.)

FIG. 13. Septas Capenſis. (Heptandria Heptagynia.)

FIG. 14. Diſandra proſtrata. (Heptandria Monogynia.)

PLATE III. Exhibits the Claſſes Octandria, Enneandria, and Decandria.

FIG. 1. Fuchſia coccinea. (Octandria Monogynia.)

FIG. 2. Gaura biennis. (Octandria Monogynia.)

FIG. 3. Vaccinium Oxycoccus. (Octandria Monogynia.)

FIG. 4. Erica Daboecii. (Octandria Monogynia.)

FIG. 5. Paris quadrifolia. (Octandria Tetragynia.)

FIG. 6. Butomus umbellatus. (Enneandria Hexagynia.)

FIG. 7. A ſeparate flower.

FIG. 8. The advanced germens.

FIG. 9. Rhododendron Chamæciſtus. (Decandria Monogynia.)

FIG. 10. Kalmia glauca. (Decandria Monogynia.)

FIG. 11. Dianthus cæſius. (Decandria Digynia.)

FIG. 12, 13. Petal, ſtamens, &c. ſeparate.

PLATE IV. Exhibits the Claſſes Dodecandria, Icoſandria, and Polyandria.

FIG. 1. Sempervivum tectorum. (Dodecandria Polygynia.)

FIG. 2. Lythrum Salicaria. (Dodecandria Monogynia.)

FIG. 3. A flower of the ſame laid open.

FIG. 4. Pyrus Malus. (Icoſandria Pentagynia.)

FIG. 5. Calyx laid open, to ſhew the inſertion of the ſtamens.

FIG. 6. Metroſideros citrina. (Icoſandria Monogynia.)

FIG. 7. Rubus odoratus. (Icoſandria Polygynia.)

FIG. 8. Capparis ſpinoſa. (Polyandria Monogynia.)

FIG. 9. Helleborus Foetidus. (Polyandria Polygynia.)

FIG. 10. Helleborus hyemalis. (Polyandria Polygynia.)

FIG. 11. Papaver Rhoeas. (Polyandria Monogynia.)

FIG. 12. Germ and Stamens of the ſame (the corolla being taken away.)

PLATE V. Exhibits the Claſſes Didynamia and Tetradynamia.

Fig. 1. Melittis grandiflora. (Didynamia Gymnoſpermia.)

* * Calyx and Corolla laid open.

Fig. 2. Stachys coccinea. (Didynamia Gymnoſpermia.)

Fig. 3. Teucrium latifolium. (Didynamia Gymnoſpermia.)

Fig. 4. Antirrhinum majus. (Didynamia Angioſpermia.)

* * Stamens and Style of the ſame.

Fig. 6. Orobanche major. (Didynamia Angioſpermia) with the parts of fructification ſeparate.

Fig. 7. Thlaſpi campeſtre. (Tetradynamia Siliculoſa) with the germen and ſtamens magnified, and a view of the capſule in its natural ſize, with a tranſverſe ſection of it.

Fig. 8. Braſſica oleracea. (Tetradynamia Siliquoſa) with the parts of fructification ſeparate.

PLATE VI. Exhibits the Claſſes Monadelphia, Diadelphia, and Polyadelphia.

Fig. 1. Ferraria Tigridia. (Monadelphia Triandria.) The ſpecies of the genus Ferraria are differently arranged by authors, ſome being placed in the Claſs Triandria, and others in the Claſs Gynandria, in which Linneus had ſtationed them. The preſent ſpecies is placed in the Monadelphia Triandria by the ingenious conductor of the Botanical Magazine, the ſtyle in this flower paſſing through the column ſupporting the anthers.

Fig. 2. Hibiſcus ſpecioſus. (Monadelphia Polyandria.)

Fig. 3. Geranium pratenſe. (Monadelphia Decandria.)

Fig. 4. Stamens of the ſame, ſeparate.

Fig. 5. Polygala vulgaris. (Diadelphia Octandria.)

Fig. 6. 7. Parts of fructification ſeparate.

Fig. 8. Lathyrus odoratus. (Diadelphia Decandria.)

Fig. 9. Stamens viewed ſeparate.

Fig. 10. Spartium junceum. Diadelphia Decandria.)

Fig. 11. Hypericum Aſcyron. (Polyadelphia Polyandria.)

Fig. 12. Calyx, with germen and ſtyles.

Fig. 13. A group of ſtamens.

PLATE VII. Exhibits the Claſſes Syngeneſia, Gynandria, Monoecia, Dioecia, Polygamia, and Cryptogamia.

Fig. 1. Cichorium Intybus. (Syngeneſia Polygamia Æqualis.

Fig. 2. A ſeparate floret.

Fig. 3. Bellis perennis. (Syngeneſia Polygamia Superflua.)

Fig. 4, 5, 6. Parts of fructification of the ſame, with a male and female floret magnified.

Fig. 7. Centaurea Cyanus. (Syngeneſia Polygamia Fruſtranea.)

Fig. 8. Florets of the ſame viewed ſeparately.

Fig. 9. Dahlia coccinea. (Syngeneſia Polygamia Superflua.)

Fig. 10. Echinops Sphærocephalus. (Syngeneſia Polygamia Segregata.)

Fig. 11. Floret of the ſame.

Fig. 12. Lobelia Dortmanna. (Syngeneſia Monogamia.)

Fig. 13. Corolla, Calyx, and Stamens ſeparate.

Fig. 14. Orchis Morio. (Gynandria Diandria.)

Fig. 15. View of Stamens of the ſame.

Fig. 16. Magnified view of a Stamen, to ſhew the ſingular appearance of the Anther.

The genus Orchis is by ſome modern botaniſts referred to the Claſs Diandria. Willdenow places it in the Order Monandria of this Claſs.

Fig. 17. Ariſtolochia Clematitis. (Gynandria Hexandria.) Willdenow places it in the Claſs Monadelphia.

Fig. 19. Corylus Avellana. (Monoecia Polyandria,) ſhewing the male flowers in ſpikes or catkins, and the female ones in the form of a ſmall tuft, at a diſtance, on the ſame ſprig.

Fig. 20. Salix caprea. (Dioecia Diandria,) ſhewing the male catkins.

Fig. 21. A ſingle male flower magnified.

Fig. 22. The female catkins of the above ſpecies, on a ſeparate individual.

Fig. 23. A ſingle female flower magnified.

Fig. 24. Valantia cruciata. (Polygamia Monoecia.) This is placed by Dr. Smith and others among its kindred Galiums in Claſs Tetrandria.

Fig. 25. Trichomanes Tunbrigenſe. (Cryptogamia. *Filices.*)

Fig. 26. Hypnum ſerratulum. (Cryptogamia. *Muſci.*)

Fig. 27. Hypnum taxifolium. (Cryptogamia. *Muſci.*)

Fig. 28. A ſeparate piece of the ſame.

Fig. 29. A ſpecies of Lichen. (Cryptogamia. *Algæ.*)

Fig. 30. A ſpecies of Agaricus. (Cryptogamia. *Fungi.*)

CORRECTIONS AND ADDITIONS.

Acanthus 8. For 195 read 295.
After Agallocha—add, *Agallochum*, ſee *Aquilaria*.
To Agroſtis—add, Agroſtis coccinea. *Symes Ava*, 479.
After Aloe—add, *Aloexylum*, ſee *Aquilaria*.
Amomum. After *Gærtn. t.* 12.—add, Claſs. 1. 1. Monandria Monogynia.
Anthemis maritima. After Montpellier—add, and England.
Aſperula calabrica. Add Pavetta foetidiſſima. *Cyrilli*.
Athanaſia *n.* 14 and *n.* 18. have the ſame trivial name, but are different ſpecies.
Bauhinia. Add Bauhinia dyphylla. *Symes Ava*, 476.
Carex Cyperoides, *n.* 6. repeated in *n.* 54.
After Ceanothus, add, *Ceanothus arborefcens* ſee *Rhamnus*.
After Chærophyllum—add, *Chætocarpus* ſee *Labatia*.
Chelone Pentſtemon. *Dele* Digitalis *Mor. hiſt.*—and, For *P. lævigata* read *Pentſtemon pubeſcens. Hort. kew.* 2. 360.
Ciſſus marifolius—add—*Berk. outl. ed.* 1. *vol.* 2. 150. *Engl. bot. t.* 396. *Smith brit.* 572. Weſtmoreland, Cumberland and Carnarvonſhire.
After Codon—add, *Codonium* ſee *Schœpfia*.
For *Convallaria* (*n.* 2.) read *Convallaria*.
Crinum teneſſum (*n.* 4.) See *Leucoium ſtrumoſum*.
Dracontium 3 read 3.
Epidendrum—add, E. moſchatum. *Symes Ava*, 478.—At the end of the deſcription of *n.* 121. add a reference to Thunberg—at the head of the next deſcription add 122—for 122 *read* 123—and, for 123 *read* 124.
Erodium, Eroteum, Ervum. See theſe articles at the end of Letter E.
Eryſimum: For Claſs 14. *read* Claſs 15.
Ervum ſolonienſe. *See Vicia lathyroides*.
Galaxia. For κυκλῳ *read* κυκλος.
Ginkgo. *See* Saliſburia.
For Glycine caribæa *read* G. *caribæa*.
Graſs *vol.* 3. *par.* 2. at the end—for LAND read MEADOW.
After Guilandinoides—add, *Guinea-graſs* ſee *Panicum*.
After IXIA ſee *Dilatris*, *Gladiolus*—add *Moræa*.
For Laurus foeteus *read* Laurus foetens.
Ledum latifolium. For Labrador Tree *read* Labrador Tea Tree.
For Lobelia Columneæ *read* Lobelia Columnæ.
Mentha—after *Juſs.* 118. *inſert Claſs.* 14. 1. Didynamia Gymnoſpermia.
Meſembryanthemum 68. *a.* for requires *read* acquires.
After Moræa ſee *Ariſtea*—add, *Siſyrinchium*.
Napæa lævis. For Malva *read* Althæa.
After NERIUM ſee *Echites*, &c.—add *Tabernæmontana*.
Orchis 11. numbered twice, and thence the numbers proceed wrong.
For Orobus 6 *read* 5.
For PANACRATIUM *read* PANCRATIUM.
In Paſſerina ciliata *dele* Sanamunda 1. *Cluſ. hiſt.* 1. 88.
Phlox. 8. deſcr. for 1788 *read* 1768.
Poa brizaides (n. 68.) *read* Poa brizoides.
Polygala mexta (n. 28.) *read* Polygala mixta.
Rhododendrum maximum: for Mill. fig. t 229. *read* 228.
Sambucus, deſcr. for the ſecond n. 3. *read* 4.
After Sebeſtena—add, *Schiſtera* ſee *Tomex*.
Smithia ſenſitiva—after 496. add *t.* 13.
For Solanum racemoſum *read* S. racemoſum.
Turnera Pumilea—leaves uniglandular.
